INFORMATION FOR CONTRIBUTORS

GENERAL

All manuscripts should be addressed to the Editor, *Current Science*, P. B. No. 8001, C. V. Raman Avenue, Bangalore 560 080. Submission of an article will be held to imply that it has not been previously published and is not under consideration for publication elsewhere; and further, that if accepted, it will not be published elsewhere. *Three copies of contributions of all categories* are required, with a letter of transmittal giving (i) names and complete addresses of the authors and (ii) title of the contribution and the category in which it is submitted (see below).

Current Science is a multidisciplinary journal and therefore research and review papers of general significance that are written clearly and well organized will be given preference. All papers will be first assessed by a Reviewing Editor. Papers found unsuitable in terms of the overall requirements of the journal will be returned to the authors. The others will be sent for detailed review. *Both solicited and unsolicited material will be reviewed.* Authors of these papers will be notified of acceptance, rejection, or need for revision of the paper. Returned papers cannot be resubmitted.

Illustrations and other material to be reproduced from other publications must be properly credited; it is the authors' responsibility to obtain permission for reproduction (copies of letters of permission should be sent).

CATEGORIES OF MANUSCRIPT

General articles (not exceeding 5000 words) discuss current trends in research in a field that will be of interest to readers outside the field; interdisciplinary topics: science policy and administration; or some aspect of the application of science and technology to human needs or the impact of science and technology on society/ecosystems/life. They should include a summary not exceeding 100 words, introductory paragraph(s), brief subheads at appropriate places to point to what follows, illustrations that will help a general reader, and references.

Review articles (not exceeding 5000 words) are expected to survey and discuss recent developments in a field. They should be well focused and organized, and avoid a general, 'textbook' style.

Research articles (not exceeding 4000 words) should report research results of fairly major significance. They should include an abstract not exceeding 100 words, introductory paragraph(s), and brief subheads.

Research communications (not exceeding 2000 words) should contain important findings that are novel and of fairly broad interest. They should include a brief abstract and an introductory paragraph. Text should not be broken up under subheads.

Correspondence includes letters, not exceeding 500 words, that are of general interest to scientists. All letters cannot be published.

Scientific correspondence contains technical comments, including those on articles or communications published in *Current Science* within the previous six months. Letters may be reviewed and edited.

Research news articles are intended to inform nonspecialists about recently published advances or important findings discussed at a meeting. Authors should also send a copy of the paper(s) on which the article is based. Meeting reports should avoid merely listing brief accounts of topics discussed, and must convey to readers the significance of an important advance.

Research accounts articles are intended to be personalized reviews of research from the authors' own laboratory, based on a body of published work. The articles must provide appropriate background to the area in a concise introduction, which should also serve to place the author's work in proper perspective. Articles will normally not exceed 8 to 10 printed pages.

Opinion articles present views on issues related to science and scientific activity. **Commentary** articles should contain expository notes on issues related to science and scientific activity.

Book reviews. Unsolicited reviews will also be considered. Reviews that merely 'list' brief descriptions of the contents cannot be published. Reviews should have 'context' and convey some information about the subject of the book.

Historical commentary and notes inform readers about interesting aspects of personalities or institutions of science or about watershed events in the history/development of science; most are expected to relate to India. Illustrations are welcome. Brief items will also be considered.

MANUSCRIPT PREPARATION

Manuscripts should be typed double-spaced on one side of white bond paper (21 × 28 cm). The pages should be numbered consecutively, starting with the title page and through the text, reference list, tables and figure legends. The **title** should be brief, specific and amenable to indexing. Not more than five **keywords** should be indicated separately; these should be chosen carefully and must not be phrases of several words. **Summary** and **abstract** should not have more than 100 words and should convey the main point of the paper, outline the results and conclusions, and explain the significance of the results.

Text. All papers should have a brief introduction. The text should be intelligible to readers in different disciplines and technical terms should be defined. Tables and figures should be referred to in numerical order. All **symbols** and **abbreviations** must be defined, and used only when absolutely necessary. Superscripts and subscripts and ambiguous characters should be clearly indicated. **Units of measure** should be metric or, preferably, SI. Methods should, as far as possible, be described briefly in appropriate table and figure legends.

Figures. In the case of line drawings one set of originals (without any lettering) is sufficient, with two copies containing lettering. In the case of photographs good prints are required with each copy of the manuscript; photocopies are not acceptable. Line drawings should be roughly twice the final printed size. The correct orientation should be indicated if not clear.

Photomicrographs and other photographs that require it must have a scale bar, which should be defined clearly in the legend. Primary data should be submitted as far as possible (e.g. actual photographs of electrophoretic gels rather than idealized diagrams).

References should be numbered in the order in which they appear, first through the text and then through table and figure legends. The following are examples of ways of writing references.

1. Mukundan, T. and Kishore, K., *Curr. Sci.*, 1991, **60**, 355–362.
2. Constantine. G., in *Biology of Bats* (ed. Wimsatt. W. A), Academic Press, New York. 1970. vol 1, pp. 319–322.

Acknowledgements should be brief. Footnotes are not allowed except to identify the corresponding author if not the first.

Cover photographs. Good photographs (colour or black and white) that pertain to a submitted paper will be considered for use on the cover. Good *prints* and a legend should be submitted with the manuscript. In the case of a colour picture, a transparency will be required for printing if accepted.

PROOFS AND PUBLICATION

Two sets of galley proofs are sent to the corresponding author. A reprint order form accompanies the proofs.

Pressure-induced phase changes in $CdWO_4$

Studies in pressure-induced phase transformation in sheelite type ABO_4 compounds by Raman spectroscopy have demonstrated that such transformations are a rule in these systems. Do Wolframite type ABO_4 compounds exhibit pressure-induced transformation (PIT) is a logical question. A. Jayaraman *et al.* answer this question in their article 'New pressure-induced phase changes in $CdWO_4$ from Raman spectroscopic and optical microscopic studies' on **page 44**.

Employing a gasketted Mao–Bell type diamond cell, the behaviour of $CdWO_4$ (Wolframite structure) at high pressures have been studied up to 40 GPa with the help of high pressure Raman spectra. The results show that wolframite phase disappears above 30 GPa and reappears at 16 GPa on release of pressure. This transition is completely reversible at room temperature and the high pressure phase is not quenchable. It is a first order transition and is hysteritic.

Identifying the highest wave number peak with ν_1 mode of WO_6, the authors argue that the decrease of the frequency of this peak by about 120 cm^{-1} in the high pressure phase (as compared to the wolframite phase) is indicative of a truly octahedral W–O coordination in the high pressure phase. They point out that the description of octahedrally coordinated WO_6 as building blocks in wolframite $CdWO_4$ is a highly distorted picture. It should really be regarded as tetrahedral and that is also consistent with the Raman frequency of WO_4 in wolframite $CdWO_4$.

Comparing their results with the ν_1 mode of the octahedral WO_6 in Ba_2CaWO_6, they conclude that in the high pressure phase of $CdWO_4$, the coordination of W becomes truly octahedral. They suggest that the WO_6 octahedrons may form chains in the structure sharing four corners with the neighbouring octahedra or from zig-zag chains sharing the edges to preserve the W–O ratio. They point out the need for additional input from high pressure X-ray study to identify the other weak peaks of Raman spectrum.

Optical observations under microscopic (in unpolarized and crossed polarized light) with thick (~ 50 μm) as well as thin (~ 20 μm) samples of $CdWO_4$ revealed a remarkable PIT near 10 GPa. This is also shown in Raman spectra, in a less pronounced way, as small changes of slope in pressure vs Raman shift plot. This subtle transition in the wolframite phase is interpreted as the wolframite lattice 12/a taking on the C2/c symmetry of $HgWO_4$.

The authors show in the case of sheelite $CdMoO_4$, the sheelite to wolframite transition near 12 GPa. Near 25 GPa, $CdMoO_4$ exhibits another transition similar to that observed in $CdWO_4$.

Based on the above results, the authors suggest that the picture for the high pressure transition sequence in $A^{2+}B^{2+}O_4$ compounds is sheelite to wolframite or wolframite-like phase and then to a phase with truly octahedrally coordinated BO_6 units.

Enzymes, Pharmaceuticals & Industrial Chemicals Ltd., BOMBAY

EPIC is an Indo-German joint venture company listed on the Bombay Stock Exchange with a turnover of about Rs.40 crores. Its main manufacturing unit and R & D Laboratories are located at Lohop, about 70 kms. South of Bombay near Panvel and with a second unit at Taloja, near Bombay. The Company produces a broad line of speciality chemicals, bulk drugs, pesticides and chemical intermediates, some of them exclusively for its European collaborators.

Of the 150 employees of the Company over 100 are grade engineers and chemists from institutions like the Indian Institute of Technology, Bombay University, Tufts University and Harvard University.

The Company has several vacancies at its R & D Laboratories at Lohop.

RESEARCH SCIENTISTS

Organic Chemists having proven ability for independent research as evidenced by publications. Minimal qualification is M.Sc. with 10 years experience and consistently good academic record or Ph.D. with three years post doctoral experience in a University or Industry. The Scientists are expected to develop innovative and cost-effective processes and procedures for making various Organic Chemicals used as pesticides, drugs and intermediates. They should be capable and willing to work with their own hands in addition to guiding junior scientists and technicians.

The position is in the Management Grade. Minimal salary and allowance is Rs.1.00 lakh per annum. Housing and transport provided.

QUALITY CONTROL MANAGER

M.Sc./Ph.D. in Organic or Analytical Chemistry with minimum 5 years of post qualification experience in the development of Analytical Test methods or Quality Assurance. He should have hands-on familiarity with HPLC, GLC and other instrumental methods of analysis. He should be able to lead a team of technicians and will be responsible for releasing materials required for production and despatch. A good working knowledge of GLP and ISO-9000 validation criteria is preferred. Excellent oral and written communication skills and the ability to work as part of a team are essential.

The position is in the Management Grade. Minimal salary and allowance is Rs.1.00 lakh per annum. Housing and transport provided.

RESEARCH OFFICERS

M.Sc. in Organic or Analytical Chemistry with minimum two years post qualification experience in Organic synthesis, Quality Control or Instrumentation. They are expected to develop synthetic and analytical methods for various speciality chemicals under the guidance of Research scientists. Starting gross salary is Rs.5000/- per month.

RESEARCH ASSISTANTS/TRAINEES

B.Sc./M.Sc. with consistently good academic record with or without research experience. Fresh candidates will be absorbed as trainees on a monthly stipend of Rs.2000/- to Rs.3000/-.

THERE IS NO LAST DATE FOR APPLICATION. EXCELLENT GROWTH PROSPECTS FOR BRIGHT HARD WORKING CANDIDATES.

HIGHER STARTING SALARY FOR DESERVING CANDIDATES.

Fancy and facts in science and art

Science is often defined as the search for truth. In a true sense, art can also be considered as the search for truth. This leads us to the often-debated fundamental question – What is truth (*'Satyam'*)? *'Sat'* in the Sanskrit word *'Satyam'* means 'that which exists forever'. This eternal fact was aptly presented by our predecessors as – *'Ekam sat vipra bahudhavadanti'* (Truth is one; scholars present it in many ways).

It is, therefore, not uncommon to feel the intermingling of the scientific quest for precision with artistic values of aesthetics. History does provide many inspiring examples. I was impressed by a statement from Charles Lindberg, whose exploits with aircrafts are legendary: 'Science, freedom, beauty, adventure: What more could you ask of life? Aviation combined all the elements I loved. There was science in each curve of an airfoil, in each angle between strut and wire, in the gap of a spark plug or the colour of the exhaust flame. There was freedom in the unlimited horizon, on the open fields where one landed. A pilot was surrounded by beauty of earth and sky. He brushed treetops with the birds, leapt valleys and rivers, explored the cloud canyons he had gazed at as a child. Adventure lay in each puff of wind'.

Barbara McClintock, undoubtedly one of this century's outstanding scientists, is a shining example whose work has embodied the elements of beauty and adventure. She dared to think differently and firmly placed her work and vision on genetic instability, duly earning a Nobel prize in 1983, though it is almost 34 years late! Aren't the anthocyanin colour patterns on the maize kernels, which incited the interest of McClintock, aesthetically appealing and beautiful in their own right?!

Probably, every scientist who takes pride in his/her work consciously realizes the innate artistic beauty of the subjects. I was, therefore, not so surprised to read the following statement by Chandrashekaran[1] in an article on biological research: 'What under the sun can possibly surpass the beauty of the feedback physiological principles involved in the capture of a moth by an insectivorous bat in the pitch darkness of a new moonlight?'

Doesn't art involve scientific elements? What better example can there be but the graphic work of M. C. Escher? Although he declared himself as 'absolutely innocent of training or knowledge in the exact sciences', Escher's drawings in the early part of this century gave expression to abstract concepts of infinity from finity, symmetry, self-similarity, precision and periodicity, stimulating the interest of mathematicians and crystallographers[2]. Aren't all these elements reflected in a good measure in the biological world as 'pattern formation', whether it is the colour patterns in the butterfly wings, anthocyanin patterns on a maize kernel, spatial periodicity of plant organs or the exine architecture of pollen?! So much so, Nijhout[3], a pioneer researcher on wing colour patterns, remarks: 'Few things in nature match the beauty and variety of the patterns on the wings of the butterflies and moths.'

Although there are several unifying principles in science and art, an important point to consider, in this context, is the degree and freedom of 'creativity'. I do find (as many must have) a basic difference in the 'creative potential' of science and art. Although science does give every scientist unlimited opportunities (at least theoretically) for demonstrating his own ego, talent, imagination and industry as in arts, the creative potential and the freedom of imagination of a poet or a writer are indeed far greater than that of a scientist. A poet could thus grant imaginative boons to a *'rakshasa'* (Hiranyakaship) that he could neither be killed by man nor by an animal, neither by a living nor by a dead weapon, neither in the day nor at night, neither on the earth nor in the sky and neither in the house nor outside. Having set all these variables, he comes out with a wonderful answer by creating a marvel of imagination – *'Narasimha'* (the Lion God) and the rest is an awe-inspiring mythological story. It is, therefore, said: *'Apaare kavyasamsare kavireva prajapathihi; ethamsmyi rochite viswam tathedham parivartate'*, broadly meaning that poet is a 'brahma' of the vast literary family; as he wishes, so he creates.

The imagination and the infinite expressions from a finite means thus depend on the talent of an artist, whether in music, painting, poetry or even in film-making, where a Spielberg can recreate dinosaurs (aided by computer technology, of course), give 'life ' to these and instantly appeal to a worldwide audience.

The ability of a scientist in playing the role of a 'creator' has increased manifold in the recent years in the biological field after the advent of genetic engineering. For instance, let us consider the recent manipulations of floral colour patterns through molecular techniques, termed 'molecular flower breeding'[4]. In nature, we do not find brick-red petunias or blue roses for the simple reason that these plants lack appropriate enzymes that catalyse certain chemical reactions in the anthocyanin biosynthesis to produce respective colour pigments. Researchers have been recently successful in introducing and expressing the gene coding for the enzyme dihydroquercetin reductase from maize into petunia, thus producing a novel brick-red petunia variety. This is

a fairly successful, commercially beneficial and environmentally harmless (apparently) application of plant genetic engineering. In contrast, several restrictions do exist in carrying out similar exercises in the animal world. The point I make is that a scientist cannot and perhaps should not have a free hand in his 'creations' as much as an artist has, and his pursuits are most often, if not always, limited by nature and other regulations imposed by man himself. Except for this variable degree of 'freedom', there may not be any fundamental difference between scientific and artistic quests for truth. The underlying similarities between science and art have been presented in a brilliant portrayal of Newton and Michelangelo by Prof. Chandrasekhar[5].

Finally, it is tempting to quote Leonardo da Vinci (cited by Dobzhansky[6]), the multifaceted personality par excellence: 'Even though the genius of man might make various inventions, attaining the same end by various means, it will not invent anything more beautiful or more economical or more direct than nature, for in nature's inventions nothing is wanting and nothing is superfluous.'

Distortion of Indian degrees

It is rather common to find that authors of research papers who are of Indian origin but now settled abroad mention their Indian degrees in a distorted form in their biographies. Here are some examples from recent IEEE publications:

1. '... received the B Eng from the Indian Institute of Science, Bangalore, in 1964 ...'
2. '... received the B S E E degree from the Indian Institute of Science in 1976 ...'
3. '... received the B S E E degree in Electrical Engineering from Bangalore University, India, in 1969 ..'
4. '... received the B S degree in electronics from the Bangalore University in 1981 ...'
5. '... received the B Eng (Electronics and Telecommunication Engineering) degree from the Bengal Engineering College, University of Calcutta in 1980 ...'
6. '... received the B S degree from Agra University, India in 1969 and M S degree from Aligarh University, India ...'
7. '... received a B S (Honours) degree in Physics from the University of Delhi, St. Stephens's College, in 1956 ...'
8. '... received the B S in Electrical Engineering from the University of Madras, India ...'

The names and references have been suppressed for obvious reasons. All the degrees mentioned above are distorted versions, as one may easily verify. IISc neither offers a B Eng nor a B S E E; neither does Bangalore University award a B S E E or B S in Electrical Engineering or a B S degree in Electronics. Calcutta University awards a B E and not a B Eng degree. None of the three Universities at Agra, Delhi or Madras offers a B S degree. Also, Aligarh University does not award an M S degree.

Why do these authors, who are some of our very best products, distort their Indian degrees? Is it their wish to conform to the US/Canadian degree? If so, why? If conformity is important, why is it that scientists of European origin do not have to resort to such distortions? Or, is it a reflection of an inferiority complex? Are B Sc, M Sc and B E inferior nomenclatures as compared to B S, M S and B S E E?

It is my impression that Indian degrees are well understood and well respected throughout the world. Such disrespect for Indian degrees, as shown by some authors, is, in my opinion, totally uncalled for, and almost amounts to falsification. What would happen to the individual concerned if one of our institutions writes to his/her employer that he/she was never awarded the stated degree?

S. C. DUTTA ROY
Electrical Engineering Department
Indian Institute of Technology
New Delhi 110 016, India

On 17 April 1995 the National Working Group on Patent Laws (NWGPL) – a nationwide non-government organization active in the area of Intellectual Property Rights (IPRs) – issued an appeal for preservation of the essential elements of the Indian Patents Act, 1970. Although it is no one's case that changed circumstances do not call for reappraisals, the scientific community has, so far, been admitted to only the outer periphery of the present debate and national decision-making on IPRs. This is all the more surprising because the generators, preservers, advancers, users, transmitters and first owners of the products of the intellect – intellectual property – are, in large measure, scientists and engineers, working within, and receiving approbation and remuneration from, the larger polity.

— Editors

Ammending the Patents Act – An appeal from the National Working Group on Patent Laws

In its appeal, the National Working Group on Patent Laws reiterated that what is at stake is not a narrow technical or legal issue. 'We are witnessing nothing short of an ever-expanding annexation of our sovereign spaces of vital decision-making. The proposed amendment of the Patents Act is being imposed on the nation. ... in line with the exclusionist and inequitable approach of the industrialized countries and their transnational corporations. The TRIPs agreement is nothing but a comprehensive and meticulous embodiment of that approach. ... [the] proposed amendment to the Indian Patents Act of 1970 [is] to make it consistent with the TRIPs agreement.'

'The issue is political and transcends "technical" or "legal" considerations. It is therefore, inappropriate to think of introducing "safeguards" in the proposed amendment. ... For the same reason, it is misleading to confine one's outlook to sectoral or superficial adverse effects and then to plead that there will be no real damage for say "seven" years.'

'There is also no question of our country ceasing to be a member of the World Trade Organization (WTO) automatically if the proposed amendment falls through [in Parliament]. Leaving aside the question of whether it is the national interest to be member of the WTO, with all its detrimental contents and its continuing, intrusive legislative mandate overriding the sovereignty of its members, there is no way of our being expelled from the WTO, only because our sovereign Parliament has decided not to approve the amendment. In many international agreements, the US executive committed itself to the requirements of these agreements after thorough negotiations, but such commitments were rejected or modified by the US legislature in the exercise of its sovereign power. The result was that the agreements were amended to accommodate US and *not* that the US was expelled from the agreements. Moreover, the expulsion from the WTO requires a decision by a three-fourths majority of its members. Such mobilization in WTO against India on this issue is next to impossible. ...'

'An apprehension is voiced that unilateral punitive action may follow. First, for any WTO-legal action, the member concerned will have to follow the route of dispute settlement procedures, which can be activated only if there is a specific cause of action. Moreover, the normal working of a democratic process can hardly provide such a cause of action for other members. However, this does not rule out unilateral, WTO-illegal action on the part of any member who wishes to bully us. But *ab initio* such action is WTO-illegal. And all the so-called protection of a rule-based system then becomes a mirage.'

A detailed analysis by the NWGPL of the provisions of the Patents (Amendment) Bill, 1995, follows.

S. no	Provision in the Patents (Amendment) Bill, 1995	Remarks
1	Preamble Whereas India is a signatory to the Agreement for the establishment of the World Trade Organization including the Agreement on Trade Related Aspects of Intellectual Property Rights for the purpose of reduction of distortions and impediments to international trade and promotion of effective and adequate protection of intellectual property rights.	There is nothing to show that the Indian Patents Act, 1970, creates distortions and impediments to trade. In the light of this it would not be desirable to resort to self-condemnation of our Patent Laws.
2	Section 24A(1) Notwithstanding anything contained in sub-section (1) of Section 12, the controller shall not, under that sub-section, refer an application in respect of a claim for a patent covered under sub-section (2) of Section 5 to an examiner for making a report till the 31st day of December 2004 and shall, where an application for grant of exclusive right to sell or distribute the article or substance in India has been made in the prescribed form and manner and on payment of prescribed fee, refer the application for patent, to an examiner for making a report to him as to whether the invention is not an invention within the meaning of this Act in terms of Section 3 or the invention is an invention for which no patent can be granted in terms of Section 4.	It would not be desirable to keep the patent application unattended. It is important to examine the patent applications in accordance with Section 12 of the principal Act, in addition to Sections 3 and 4. The TRIPs Text specifies that exclusive marketing right is to be given and not exclusive right to 'sell or distribute'. Exclusive right for distribution may not be tenable under the MRTP Act. It is important to examine whether the article or substance is not in public domain. The invention has to be new, involve an inventive step and should be capable of industrial application to qualify for an exclusive marketing right.

3 Section 24A(2)

Where the Controller, on receipt of a report under sub-section (1) and after such other investigation as he may deem necessary, is satisfied that the invention is not an invention within the meaning of this Act in terms of Section 3 or the invention is an invention for which no patent can be granted in terms of Section 4, he shall reject the application for exclusive right to sell or distribute the article or substance.

as above

4 Section 24A(3)

In a case where an application for exclusive right to sell or distribute an article or a substance is not rejected by the Controller on receipt of a report under sub-section (1) and after such other investigation, if any, made by him, he may proceed to grant exclusive right to sell or distribute the article or substance in the manner provided in Section 24B.

In the TRIPs Text, the connotation used is exclusive marketing right and not exclusive right to sell or distribute. Public objection should also be invited.

5 Section 24B(1)

Where a claim for patent covered under sub-section (2) of Section 5 has been made and the applicant has:
(a) where an invention has been made whether in India or in a country other than India and before filing such a claim filed an application for the same invention claiming identical article or substance in a convention country on or after the 1st day of January, 1995 and the patent and approval to sell or distribute the article or substance on the basis of appropriate tests conducted on or after the 1st day of January 1995, in that country has been granted on or after the date of making a claim for patent covered under sub-section (2) or Section 5; or

(i) Patent must be obtained in the country of invention on a product prior to the claim made under sub-section (2) of Section 5.

(ii) If the patent application has been rejected in other convention countries, it would be desirable to know the status of such applications.

6 Section 24B(1) (b)

Where an invention has been made in India and before filing such a claim, made a claim for patent on or after the 1st day of January 1995 for method or process of manufacture for that invention relating to identical article or substance and has been granted in India the patent therefor on or after the date of making a claim for patent covered under sub-section (2) of Section 5,

Process patents are already granted in India and therefore EMR on products arising out of patented processes cannot be granted.

7 Section 24B(1) (b) – sub-para

and has received the approval to sell or distribute the article or substance from the authority specified in this behalf by the Central Government, then he shall have the exclusive right by himself, his agents or licensees to sell or distribute in India the article or the substance on and from the date of approval granted by the Controller in this behalf till a period of five years or till the date of grant of patent or the date of rejection of application for the grant of patent, whichever is earlier.

(i) The relevant authority, e.g., Drug Controller, from whom marketing approval is to be taken should specifically be mentioned in the text.

(ii) Public opposition to marketing approval should be invited.

8 Section 24B(2)

Where the specifications of an invention relatable to an article or a substance covered under sub-section (2) of Section 5 have been recorded in a document or the invention has been tried or used, or the article or the substance has been sold, by a person, before a claim for a patent of that invention is made in India or in a convention country, then the sale or distribution of the article or substance by such a person, after the claim referred to above is made, shall not be deemed to be an infringement of exclusive right to sell or distribute under sub-section (1).

Since the article or the substance is already in the public domain, no exclusive right can be given.

9 Section 24C

The provision in relation to compulsory licences in Chapter XVI shall, subject to the necessary modifications, apply in relation to an exclusive right to sell or distribute under Section 24B as they apply to and in relation to a right under a patent construed accordingly, namely: to sell or distribute and for that purpose the following modifications shall be deemed to have been made to the provisions of that chapter and all their grammatical variations and cognate expressions shall be construed accordingly, namely:

(i) Indian Patent Act, 1970, provides for Licences of Right which is more appropriate as compared to compulsory licences.

(ii) Licences of Right should only be granted to encourage local production and not marketing.

(a) throughout Chapter XVI,
  (i) working of the invention shall be deemed to be selling or distributing of the article or substance,
  (ii) references to 'patents' shall be deemed to be references to 'right to sell or distribute',
  (iii) references to 'patented article' shall be deemed to be references to an 'article for which exclusive right to sell or distribute has been granted'.

Local production, and not 'selling and distribution', should be considered as working.

Binding and release of polypeptides during groEL-mediated folding: Its cellular significance?

Amitabha Chaudhuri

groEL is an *E. coli* homologue of the hsp-60 family of chaperone proteins called chaperonins. Besides groEL, the chaperonin family of proteins includes rubisco subunit-binding protein and hsp-60, which share 60% amino acid identity among themselves[1,2]. The eukaryotic protein t-complex polypeptide-1 (TCP1), although unrelated to hsp-60 class of proteins, is also a member of the chaperonin family[3].

The groEL protein was originally identified in *E. coli* as a component whose deficiency resulted in defective morphogenesis of bacteriophage λ, T4 head structures and T5 tail structures[4,5], thus suggesting for it a role in protein assembly. The gene encoding the groEL protein, groE, is essential for bacterial growth at both normal and heat shock temperatures[6]. During heat shock, the groEL protein increases 10-fold, thereby constituting 10% of the total cytoplasmic proteins[7]. The induction of groEL under stress suggests that the function of the protein is required to a greater extent under stressful conditions, when cellular proteins are likely to be destabilized with the loss of their native structure.

Evidence for the participation of groEL in protein folding comes from experiments done both *in vivo* and *in vitro*. Mutants of groEL failed to promote proper folding of their cytoplasmic proteins[8], suggesting that groEL assists newly synthesized cytoplasmic proteins to reach their native tertiary structure. groEL also promotes oligomerization of rubisco[9] and folding of a host of other unfolded *E. coli* proteins *in vitro*[10].

groEL is a large cylindrical oligomeric protein with 14 subunits arranged as two-stacked rings of seven subunits each[11,12]. Each ring forms a cage-like structure[13] which binds polypeptides in a central cavity[14] (Figure 1). Cryoelectron microscopy of groEL and complexes of groEL with ATP and groES have revealed conformational changes in the molecule with the formation of each complex[15]. Each subunit of groEL probably has an ATP-binding site[16]. The stoichiometry of substrate binding indicates that the 840 kDa groEL particle binds one or two substrate molecules. The substrate protein is believed to be sequestered in a 6 nm central cavity as a compact-folding intermediate[17].

The crystal structure of groEL at 2.3 Å resolution[18] has thrown light on the structure–function relationship of the chaperonin protein[19]. Each ring of seven subunits is folded into three distinct domains: the apical domain, which binds the substrate polypeptide; the equatorial domain, that forms the contact surface between the two rings; and the intermediate domain that connects the apical to the equatorial domain. The latter harbours the ATP-binding site.

The structure of groEL has been used as a framework for an extensive mutational analysis by Fenton *et al.*[20]. Mutant groEL molecules defective in the binding of one or more of its three ligands – unfolded polypeptide, groES and ATP – have been obtained. The polypeptide-binding domain mapped exclusively to that segment of the apical domain that faces the central channel. In this domain there are eight highly conserved hydrophobic amino acids, and changing any one of them is sufficient to abolish polypeptide binding. The amino acid composition of the polypeptide-binding domain confirms the prediction that the chaperonin protein interacts with the substrate polypeptide through hydrophobic patches.

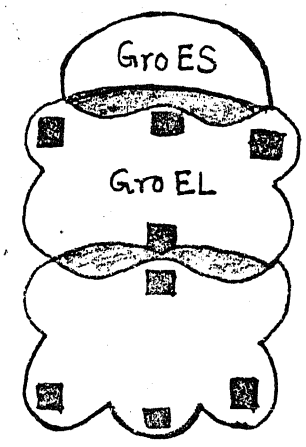

Figure 1. A diagrammatic representation of groEL–groES–ATP complex. groEL is shown as two-stacked rings with bound ATP (■). The shaded region represents the cavity within the groEL cylinder in which the substrate polypeptide is sequestered.

The same mutations that abolish polypeptide binding also affected the binding of groES. This raises the interesting possibility that the release mechanism of the polypeptide may involve a physical displacement by groES. The crystal structure of groEL and the mutational analysis has, therefore, vindicated many of the predictions that were derived from biochemical evidences.

Contribution of groEL in protein folding

The classic *in vitro* studies of Anfinsen[21] showed that folding of proteins is apparently a spontaneous process solely dictated by the primary structures. This conclusion seems now to be an oversimplification owing to markedly different conditions of protein folding *in vitro* and *in vivo*.

Whereas *in vitro* folding reactions are initiated at low temperatures, at low protein concentrations and with a complete polypeptide chain, *in vivo* folding occurs at high temperatures, at high protein concentrations and even before complete synthesis of polypeptide has occurred. As a consequence of the conditions *in vivo*, a nascent unfolded polypeptide chain is likely to interact with other unfolded protein molecules through their interactive surfaces, forming aggregates. The role of the chaperonin protein is to prevent unproductive incorrect interactions between these polypeptides which would otherwise act as kinetic dead-end traps[3]. This function is accomplished by noncovalent binding of groEL to exposed interactive surfaces of proteins, producing stable complexes. groEL might also interact with proteins trapped in misfolded forms, enabling them to assume productive correctly folded conforma-

tions[22]. These functions of the chaperonin protein require that they interact with the substrate proteins promiscuously and also bind unfolded proteins with higher affinity than their native counterparts.

groEL binds to a large fraction of denatured *E. coli* proteins[10]. Using labelled pre-β-lactamase and chloramphenicol acetyl transferase it was shown that upon their synthesis in a bacterial translation system, these proteins form complexes with groEL. The bound proteins could be displaced only by denatured myoglobin, indicating affinity of groEL for denatured substrates[23]. groEL also prevents proteins from undergoing aggregation upon dilution from a denaturant. Using rhodanese and dihydrofolate reductase it was shown that both the proteins bound groEL in a state intermediate between unfolded and the native state as characterized by proteinase sensitivity[17], affinity to ANS and intrinsic fluorescence properties[16, 24]. Thus, groEL provides a microenvironment where unfolded proteins are kept isolated from the bulk milieu, preventing unproductive interaction and thereby enabling proper folding.

The binding of unfolded proteins to groEL does not assure their proper folding. Complete folding requires the participation of a co-chaperonin groES, and ATP hydrolysis[25, 26]. The role of groES is not well-characterized except that it increases the cooperativity of binding and hydrolysis of ATP by groEL[27].

The hydrolysis of ATP during groEL-mediated folding suggests that unlike protein folding *in vitro*, protein folding *in vivo* is energy-consuming. This energy barrier is likely to serve three functions: (a) preventing free exchange of groEL-bound proteins with the other unfolded polypeptides; (b) allowing limited folding of the polypeptide on the surface of groEL and (c) facilitating the release of the protein from groEL.

The release of the protein from the chaperonin protein raises the question of whether the protein is released in its native or nonnative conformation. If a protein is released in its native conformation, it will not interact further with the chaperonin protein. However, if the protein is released in a nonnative conformation, it is likely to interact with other groEL molecules till it reaches the native state. Therefore, groEL-mediated folding of proteins involves either one or several rounds of binding and release of the polypeptides. How does one distinguish between these possibilities?

This question has been addressed rather elegantly in a paper by Weissman *et al.*[28], who have developed a technique to capture partially folded substrate proteins should they be released intermittently during their folding in the presence of groEL. In this technique mutant groEL molecules are employed, which bind substrate proteins only in their unfolded/partially folded form but do not release them even in the presence of Mg-ATP. Using ^{35}S-labelled rhodanese and ornithine transcarbamylase, they have shown that when mutant groEL protein is added in a folding reaction initiated with wild-type groEL, groES and Mg-ATP, it results in the capture of labelled proteins by the mutant groEL. In the absence of either groES or Mg-ATP, the mutant groEL fails to trap the enzymes. This observation suggests that the substrate protein is indeed released from groEL during folding and this release requires the participation of groES and ATP hydrolysis. A kinetic analysis of the process revealed that whereas complete folding requires 7 min (judged by the recovery of enzyme activity), the mutant groEL was able to trap the folding intermediates within 0.5 min of initiating the folding reaction, indicating that the substrate protein was unable to attain its native conformation upon interaction with one chaperonin molecule. To determine whether the process of binding and release of polypeptides occurs throughout the folding reaction, mutant groEL was added at different time intervals after the folding reaction was initiated. Addition of mutant groEL to the folding reaction 2 min after initiation resulted in the capture of more than 60% of the substrate polypeptides. When the mutant groEL was added 5 min after the initiation of the folding reaction, about 50% of the substrate protein was captured. This observation of Weissman *et al.*[28] suggests that the release of the polypeptide occurred throughout the folding reaction, and with increased time interval the amount of unfolded protein in the reaction mixture declined. Therefore, chaperonin-mediated folding of proteins involves several rounds of binding and release from groEL. Each cycle of binding and release is expected to require hydrolysis of 14 ATP molecules, suggesting that the requirement of 100 ATP molecules for the *in vitro* folding of one rhodanese molecule may not be an overestimation[16].

Why cannot a protein complete its folding without going through iterative cycles of binding and release? It could save the cell a substantial amount of energy. The fact that this process has been selected for in spite of it being energy-inefficient suggests that there may be something important associated with this process such that the cycles of binding and release become indispensable. The iterative interaction of a polypeptide with groEL may help to serve the following important functions:

1. As mentioned earlier, the host polypeptide is noncovalently associated with groEL through its interactive surfaces. These surfaces are, therefore, unavailable for any intramolecular interaction during the folding of the polypeptide. This is likely to result in an impasse in which the release of these interactive surfaces from groEL becomes a prerequisite for folding to proceed. In such a situation, the partially folded polypeptide has two options: (i) it can fold within the cavity of groEL by sequential release of the interactive surfaces from one or more subunits of the groEL molecule, as has been suggested by Hendrick and Hartl[17]; (ii) or it can get released from the chaperonin protein into the bulk milieu and undergo intramolecular interactions to reach their native state. The first option to be fruitful requires that the noncovalently associated interactive surfaces of the polypeptide be released from groEL in a sequential manner as defined by the folding pathway of the protein. Since this is difficult to achieve mechanistically, the second option of dissolving all interactions simultaneously and releasing the polypeptide in the bulk solution is expected to occur.

2. In the assembly of oligomeric proteins individual subunits interact with each other to form the oligomer. The interaction between subunits during oligomerization requires that each subunit bear specific patches on themselves that are recognized by other subunits. The presence of such exposed interactive patches is likely to promote aggregation, especially if the subunits are allowed to interact with each other randomly. The role of the chaperonin protein is, therefore, to hold the monomers, thereby preventing any unproductive interaction, and release them at a time when fruitful interaction

will result in proper oligomerization.

3. Proteins with sulphydryl groups or proline residues undergo thiol/disulphide exchange reaction and proline *cis/trans* isomerization during folding[29, 30]. These reactions are catalysed by the enzymes protein disulphide isomerase and proline *cis/trans* isomerase, respectively. Release of partially folded polypeptide from groEL is a prerequisite for it to interact with these enzymes.

4. Proteins may be marked for degradation during rounds of binding and release from the chaperonin molecule. The participation of groEL and groES in the breakdown of CRAG (a fusion protein containing at its amino terminus 12 amino acids of the cro repressor, followed by a truncated form of protein A and 14 amino acids of β-galactosidase at its carboxy terminus) has been demonstrated[31]. Although the mechanism is not understood, association of CRAG with groEL seems to be the rate-limiting step in CRAG degradation. This observation reveals yet another complexity in the function of groEL.

5. The release of a polypeptide from groEL may be important in limiting the amount of time a polypeptide may spend on the chaperonin molecule. This is likely to prevent the chaperonin proteins from remaining locked up in a bound state for a long time, thereby making them unavailable for other unfolded proteins. This is expected to assume importance during stressful conditions, under which the unfolded proteins are likely to outnumber the chaperonin molecule. In the groEL-mediated folding, the release of polypeptides, therefore, assumes importance in defining the number of cycles of interactions each polypeptide undergoes before reaching its native state. In other words, some proteins may require one round of binding and release while other proteins may require many before reaching their respective folded conformations.

The requirement of groEL in assisting the folding of a host of proteins both *in vivo* and *in vitro* raises the question whether all proteins require chaperonins for folding *in vivo*? If not, how do chaperonins distinguish between these proteins, especially when every protein molecule starts its life from an unfolded polypeptide chain? One explanation can be that a protein which does not require a chaperonin for folding *in vivo* has less interactive surfaces for the binding of the chaperonin protein, or the interactive surfaces may become inaccessible during early steps of folding. These proteins, therefore, not only obviate the need of a chaperonin but also avoid unproductive interactions with other protein molecules during the course of folding. In this light, one can, in fact, classify proteins as being slow- or fast-folding, and in line with

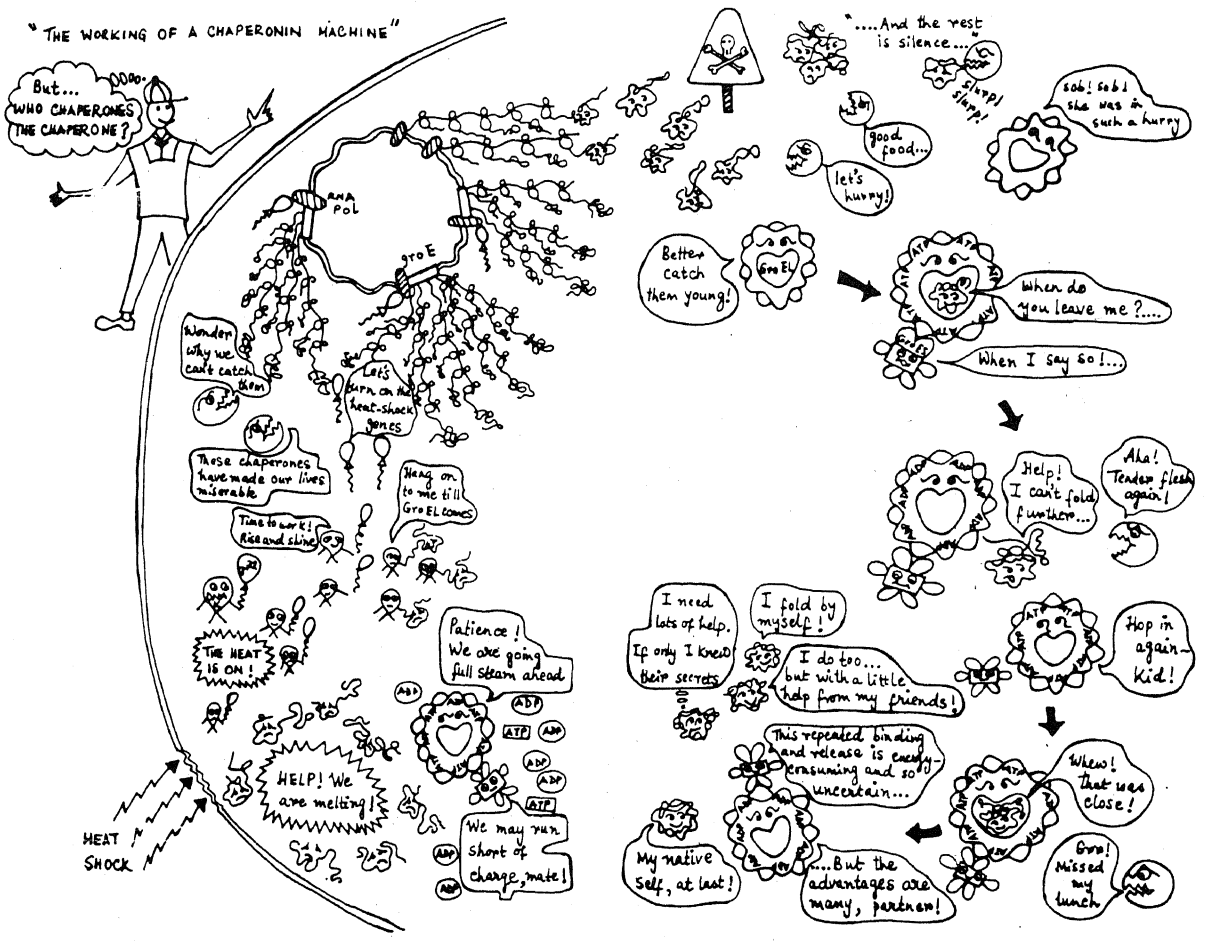

Figure 2. The working of a chaperonin machine.

this argument, the slow-folding type is likely to require the assistance of chaperonin proteins for their proper folding. The trapping method developed by Horwich's group will be invaluable in classifying proteins into these two groups. This can be achieved by determining the relative amount of time a protein spends on a chaperonin molecule before completion of chaperonin-mediated folding. For this, different proteins can be tested for their ability to fold *in vitro* in the presence of groEL. After the folding reaction is initiated with wild-type groEL, groES and Mg-ATP, the mutant groEL can be added to the reaction mixture after different periods of time and the relative amount of substrate protein that is trapped by the mutant groEL determined. A protein which goes through less number of iterative cycles of binding and release before reaching its native structure will be inefficiently trapped by the mutant groEL in contrast to proteins which complete fold through many such iterative cycles. The former can be classified as fast-folding and the latter as slow-folding types. A comparison of the sequences of these two classes of proteins is likely to reveal sequence motifs that are important in limiting the interaction of any protein with the chaperonin.

In conclusion, the detailed working of a chaperonin machine is depicted in Figure 2 with the help of a cartoon diagram.

COMMENTARY

Importance of basic research in the context of global change*

R. Chidambaram

This is a time of transition for Indian science. There is economic liberalization at home and there is the end of the cold war – at least in its earlier avatar – abroad. And there is a demand for environmentally benign and eco-friendly sustainable development. How should the Indian science and technology system react to these changes?

Any activity – political, military, economic, scientific or cultural – must have only one objective in view, namely, how to improve the quality of life of our citizens while ensuring the security of the country. We should quickly put India on to the fast track of national development and keep it there, without sacrificing the values for which the country has always stood for. We have the unfortunate tendency, as Indians, to denigrate ourselves too much. I do not think we have done too badly in any sphere since independence, though our talents and our resources could have made higher levels of achievements possible.

The attack on the Indian university system explicit in the proposal for the National Science University – discussed so well in recent issues of *Current Science* – is a case in point. The arrogance of that proposal is matched only by its absurdity. How can one ignore the excellent work done by a very large number of Indian scientists who have spent all the time of their professional careers in this country and imagine that a group of NRI scientists, working part-time and starting from scratch, will transform the scientific education scenario in the country? Have these people heard of

*Based on the lecture given at the Symposium on S&T Policy and Economic Reforms, organized by Dr P. S. Lokanathan Memorial Society, Bangalore, on 15 March 1995.

the green revolution and the oil exploration effort which led to the discovery and exploitation of Bombay High? Are they aware of the impact that some national laboratories like the NCL and some university departments like the UDCT of Bombay University have had on the Indian chemical industry? How have Indian scientists and technologists been able to build nuclear reactors, launch satellites or build sophisticated missile systems, using young men trained indigenously?

And these achievements have been possible in spite of technology control regimes that are operating now in strategic areas of high technology, which deny India some kinds of equipment and technologies in the name of non-proliferation and missile technology control. They also serve the interests of rich and developed countries by preventing diffusion of technologies needed for development by other countries. As long as Indian industry in non-strategic areas tends to generally use yesterday's technology, it will not be affected much by these technology control regimes. But as India becomes globally more competitive, Indian industry will find such regimes becoming operational for commercial reasons also and outside sources of technology will dry up. That is when the Indian industry will begin to feel more and more the need for indigenous R & D support.

What we are talking about above is applied research (where the motivation is to gather new knowledge with utilitarian objectives) and technology development (where the motivation is to create a product or a process). The reasons to support basic research (where the motivation is to gather new knowledge to satisfy curiosity) have to be sought elsewhere.

Support to science

The spurt in support to science, both basic and applied, in USA and in erstwhile USSR, was driven by the exigencies of the Second World War and then by the Cold War. There is perceptible change now in their approach to science – perhaps temporary – which seems to be caused by systemic boredom, accompanied by personal disinterest, with only a few young native Americans and Russians opting for a career in scientific research. In USA there seems to be a feeling 'What more can Science deliver?'. In Russia, whose economy has collapsed for the present in spite of their outstanding achievements in science and technology, the tendency could be to blame the latter for their present difficulties. The situation in India is very different.

We should not lose sight of our long-term perspective while pursuing short-term goals. In pursuing short-term and essential objectives, we should also not forget that India is *not* a small country. I am convinced that there is no frontier area of science and no area related to any high technology to which India should not commit itself – the extent of the commitment should depend on how far in the future such areas are likely to have an impact on India. To take a few examples, we should take measures to eliminate vitamin A deficiency in children and pursue other aspects of preventive health care but also participate in the global search for cures for AIDS and cancer. There is also no conflict between delivering economical non-conventional energy systems to rural areas and doing research on fast breeder reactors. India's relatively higher thrust must, of course, be in areas related to critical and strategic technologies and to agriculture, biotechnology, information technology and materials technology. But other areas must not be neglected.

Basic and applied research

The distinction between basic research and applied research is often blurred. The study of the origin of life or of the origin of the universe are fascinating fields but are clearly examples of basic research. But there are many situations where motivations for both kinds of research coexist. One of my colleagues is studying the structure of the HIV protease enzyme using the X-ray crystallography technique, which is an interesting basic research problem in itself. But his other purpose is to design an inhibitor for this enzyme which is the one which opens the protein coat of the AIDS virus and makes it infectious. My own studies on the equation of state and phase transformations at high pressures have had both a basic research motivation and an earlier applied research one related to peaceful nuclear explosion phenomenology. Similarly other studies in BARC on fission phenomena have had both basic research interest and an applied one related to the design of better and safer nuclear reactors.

Why support basic research?

The primary motivation for government or industry support to research is to help technology development for peaceful or defence purposes. But government support to basic research should have other motivations, which should be analysed in a national perspective. There is, of course, the duty of the state in any civilized country to allow intellectuals the opportunity to let their curiosity wander in trying to understand natural phenomena or ask and to answer questions of all kinds. Imagine the possible achievements of Srinivasa Ramanujan – 'the magical genius' as Kak once called him – if he had been supported by the government.

After a lecture by Michael Faraday (1791–1867) in the Royal Society, on the newly discovered phenomenon of electricity, a politician asked him: 'That was very interesting, but will it ever be used for anything?'. Faraday replied: 'Sir, one day you will tax it'. Some results of basic research do get converted into products and processes producing a great deal of wealth. But the support to basic research in India cannot be based on such possibilities.

Basic research is needed in Indian Universities to improve the quality of teaching. A teacher who is also doing research is much more in touch with the latest developments in his subject. Basic research is needed in national laboratories to support applied research and technology development and to attract the best intellects. In both the Manhattan Project and the Pokharan PNE Experiment Project, there was need for basic research scientists. The gaps in advanced applied research and technology development efforts can often be filled only by the expertise and knowledge available with basic research scientists.

International interactions and flow of information

Success in basic research at the international level is a matter of national pride. Applied research scientists and technology developers, though they create national wealth, are unfortunately less visible.

The national psyche needs eminent scientists like C. V. Raman, Srinivasa Ramanujan, M. N. Saha, S. N. Bose, Hargobind Khorana and S. Chandrasekhar to make us feel proud. But these are

basic research scientists. So was H. J. Bhabha, who transformed himself from a basic research scientist to a science manager.

There is another important aspect of basic research which is very relevant to Indian interests. The flow of information is free in the international basic research community and this is the knowledge that could form the basis for future technology development. Information flow gets restricted when you come to applied research and is totally blocked, unless you pay for intellectual property rights, once technology development is complete. In the field of crystallography, for example, with which I am familiar, a great deal of information on drug design is freely available in the basic research community and could be profitably used by the Indian pharmaceutical industry for its own technology development.

It may appear a contradiction of sorts but it is a fact that the latest technologies are needed for basic research and are, therefore, often first developed in large basic research laboratories. It is in India's interest to participate in international mega-projects in science.

Conclusion

Basic research is, of course, the fountainhead of ideas for technology development. The applied research edifice in India today is weak, except in mission-oriented agencies. Its growth in the future will be sustained by building a strong basic research foundation *now*. Otherwise, we run the risk of stifling our future S & T agenda. Of course, the S & T community must have a commitment to indigenous technology development. And the nation and its political system must have faith in the scientists. As Frederick Seitz once said: 'The advance of science requires money given with appreciation and wisdom.'

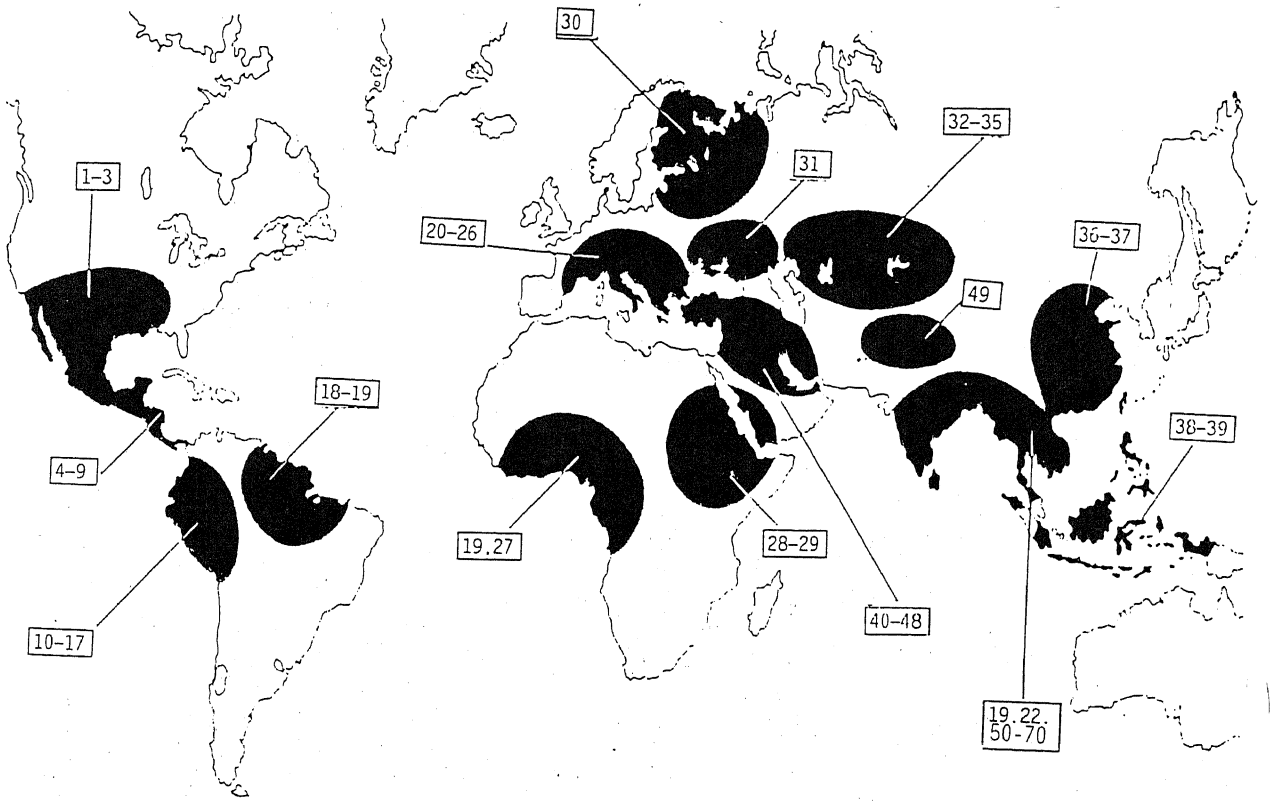
Census of India's biodiversity: Tasks ahead

T. N. Khoshoo

There are varying and often conflicting estimates floating around nationally and internationally regarding India's biodiversity, particularly the number of animal species. Thanks to A. K. Ghosh (Director, ZSI), reliable information has been collated on animal species. Based on the current knowledge as summarized by Ghosh[1], Khoshoo[2] and Singh[3], the total number of living species identified in India so far is 126,188 (Table 1). With the publication of this table, speculations about the extent and nature of species richness in India should be set to rest till such time a formal census is undertaken.

According to the World Conservation Monitoring Centre (WCMC)[4], the total number of species described at the global level so far is 1,604,000. However, this Centre estimates that at the global level there are likely to be 17,980,000 species. i.e. about 11 times more than the presently known species. The increase is likely to be primarily from the tropics and subtropics. However, a more realistic and a working figure for species[4] at the global level is around 12,250,000.



Out of the 126,188 species described from India (Table 1), Monera (bacteria) are 850 species (0.67%), Protista (Protozoa only: minus their multicellular descendants) 2577 species (2.04%), Fungi 23,000 species (18.23%), Animalia 74,875 species (59.27%) and Plantae 24,886 species (19.79%). Nearly 72% of India's biowealth is constituted by fungi (18.23%), insects (40%) and angiosperms (13.50%). This tallies generally with the overall trend seen in tropics and subtropics. Although India has only 2.4% of the land area of the world as a whole, according to the present estimates, India's contribution to the global biodiversity is around 8% species. While India stands seventh as far as the number of species contributed to agriculture (including animal husbandry) is concerned, qualita-

Table 1. Number of biota in India[1–3]

Taxon	Number of species	Percentage
Bacteria	850	0.67
Algae	2500	2.00
Fungi	23,000	18.23
Lichens	1600	1.30
Bryophyta	2700	2.14
Pteridophyta	1022	0.80
Gymnosperms	64	0.05
Angiosperms	17,000	13.50

tively India's contribution to agribiodiversity is indeed very impressive[5]. Among other species, Indian region has contributed zebu, mithun, chicken, water buffalo, camel, rice, sugarcane, banana, tea, mango, cucumber, egg plant, citrus, jute, minor millets, Asiatic vignas, brassicas, rice bean, tree cotton, jackfruit, edible dioscoreas, alocasia, colocasia, amorphophallus, cardamom, black pepper, ginger, turmeric, vegetable amaranths, cucurbits, several umbellifers, bamboos, a number of medicinals, aromatics and ornamentals, etc. (Figure 1; refs. 5 and 6). Besides, India has also been a secondary centre of domestication for horse, goat, sheep, cattle, yak, donkey, tobacco, potato, red pepper, grain amaranths, maize, soyabean, oil palm, etc. Some of these species are very early introductions into India. These have undergone evolution in the Indian region and have been selected in historical time to meet the human needs suiting Indian conditions. India has also contributed very important genes to world agriculture and animal husbandry which have made significant difference to better the human welfare[2].

All the present-day crops and domesticated animals known today were spotted and initially domesticated by the so-called early humans (particularly women). There have not been any additions to the traditional crop and domesticated animal species for the last 10,000 years. This shows the intuitive power of the ancient agriculturists for picking the right kind of animals and plants for domestication. Thereafter, modern science of genetics and breeding has not added any new crop or domesticated animal, but has no doubt increased their productivity beyond measure. However, in time to come, new additions are likely to be from amongst microorganisms for providing new products. They are likely to be the future biofactories as is the case for human insulin. Microorganisms have a big arsenal of enzymes which can perform varied and often weird tasks. Furthermore, these organisms have been performing a unique function from the day plants began to first emerge from sea and colonize totally sterile and barren land devoid of any organic matter. This was rendered possible on account of the mutualistic association between plants on the one hand, and bacteria and fungi on the other, thus helping in the uptake of nutrients by plants. Such mutualistic associations between land plants and microorganisms is seen in most of the fossil species of the then land plants colonizing the earth

nearly 408 to 387 million years ago. For instance, microscopic examination of most fossil plants shows ectomycorrhiza and endomycorrhiza.

Taxonomists: A vanishing tribe

At present good taxonomists are indeed highly endangered specialists among biologists, although India is among the very few countries to have Botanical and Zoological Surveys (BSI and ZSI) which have been rendering yeoman service against all odds. These Surveys in particular and taxonomists in general are today overshadowed by the so-called and more often second-rate biotechnologists and environmentalists. There is, however, no doubt that more investments (accompanied by strict accountability) have to be made in genetics, breeding, biotechnology, and pharmaceutical sciences for gene and drug prospecting and product development. But the country has to realize that *all wisdom begins by calling all living (including humans) and nonliving things by their proper names*. This makes the role of taxonomists most important for all development involving biologicals.

Up to early 1980s, Indians have made world-class contributions in modern taxonomy, biosystematics, experimental taxonomy, circumscription of gene pools and the allied applied aspects. From this work a large number of products (by way of new cultivars) were developed which helped the country in food self-sufficiency and better varieties in horticulture and floriculture and economic animals. Such contributions emerged from some universities in general, but principally from some of the laboratories under the Indian Council of Agricultural Research (ICAR) and the National Botanical Research Institute under the aegies of the Council of Scientific and Industrial Research (CSIR).

Apart from taxonomists, a large number of persons in different trades use taxonomic and floristic information in their work. These are: teachers from primary to adult, to college and to university level for purposes of education in biology, land-use managers, environmental surveyors, geneticists and breeders, biotechnologists, biochemists, microbiologists, pathologists, anatomists, palynologists, embryologists, physiologists, pollination biologists, seed laboratories, nurserymen, forest managers, silviculturists, weed and pest control specialists, fertilizer manufacturers, food quality controllers, agricultural consultants and extension workers, animal feed companies, indigenous medical herbalists using natural medicine, pharmacognostical and pharmaceutical researchers, drug companies, natural dye specialists, dermatologists, toxicologists, allergy specialists, forensic science specialists, ecologists, environmentalists, mining engineers, real-estate appraisers, municipal and regional planners, recreation planners and managers, sports-field managers, landscapists, architects, civil engineers, interior designers, water-way managers, flood control engineers, craftsmen, custom officials, border and enforcement agencies, lawyers, mathematicians, computer scientists and a host of other specialists[7].

The kind of information needed for basic biological, agricultural, biotechnological and pharmaceutical research is: correct identification and accurate naming, reference, systematic relationship, information on intraspecific variation, cultivars, hybrids, size of population, host–parasite relationship, phenology, economic factors, variation, distribution, habitat preference, protection status, etc. This involves many disciplines like anatomy, chemistry, embryology, palynology, cytology/cytogenetics, crossability, genetics, ecology, evolutionary biology, molecular biology, population biology, size of gene pool, etc. Such information need not be generated for all the species, but for those that are related to agribiodiversity and drug industry. Furthermore, conservation biology is becoming a very important field of study and taxonomy is the first and foremost input into this emerging discipline.

Biology at molecular and cellular levels has to be funded, particularly because in India there are some outstanding performers at two or three centres in the country. India has a major stake in this area so as to acquire bargaining power while buying and selling biotechnology and its products. However, the general clan of biotechnologists is not likely to make any worthwhile contribution in the foreseeable future despite heavy investments. This is clear from a critical appraisal of the work done so far with not much on the horizon. However, biology at a grosser level poses equally interesting problems which are likely to be of immediate benefit to science and society. Bawa[8] has rightly concluded that in India world-class work has been done in the past and can be done in future also in such areas involving much less fiscal inputs but with equal if not greater utility.

Partly, the decline in taxonomy is the result of apathy of the biologists themselves, who have willingly taken to the bandwagon of second-rate environmental and biotechnological work. Then followed the increasingly lower priority given to taxonomy and allied subjects not only by the Ministry of Environment and Forests (MoEF) but also by the University Grants Commission, CSIR and ICAR, Department of Science and Technology (DST), etc. According to Father C. Saldanha, taxonomy is unfortunately now regarded as 'tax-on-me'. Such an image of this subject must change at the earliest.

In USA, thanks to the Systematics Agenda 2000 (SA 2000)[9], taxonomy has got a shot-in-the-arm and is poised to become a money-spinner. Proper identification of taxa is of fundamental importance and is going to be a lucrative business on account of tremendous stress on biological products.

SA 2000 is an important study which involved three American Societies of taxonomists and systematists supported by the US National Science Foundation. Initially, they resolved themselves in 27 Standing Committees involving over 300 scientists representing a broad array of institutions and specialities. Their reports were reviewed critically both nationally and internationally. The result was identification of three interrelated missions: namely, (1) to discover, describe and inventorize global species diversity (i.e. discovering biological diversity); (2) to analyse and synthesize the information derived from this global discovery effort into a predictive classification system that reflects the history of life (i.e. understanding biological diversity); and (3) to organize the information derived from this global programme in an efficiently retrievable form that meets the needs of science and society (i.e. managing systematic knowledge).

The value of the study lies in the use of biodiversity for human health, medicine and pharmaceuticals, agriculture, genetic resources, forestry, fisheries, species economics, understanding and conserving earth's life support system, enhancement of quality of everyday life and scientific

research base, etc. In short, this effort is an initiative to discover, describe and classify the biota of the world.

In India, special attention has also to be paid to the marine biodiversity, including mangroves. Let us not forget that our country has been endowed with a long coastline and an extended economic zone (EEZ) which is nearly as large in area as the country itself. We know almost next to nothing about this treasure trove.

It is high time that Indian authorities (especially DST and MoEF) consider bringing together a group of informed biologists to do some deep introspection and chalk out a strategy to halt the decline in taxonomy, and revitalize the subject so as to meet the newer and unforeseen challenges of the future.

Biological Survey of India

Another task that merits attention of such a committee is to bring together BSI and ZSI into one connected whole, as Biological or Ecological Survey of India, where botanists, zoologists, ecologists, conservation biologists and others using the most modern tools and skills, including space science, bring out a consolidated picture about Indian biota, their distribution, composition, endemism, rarity, extent and nature of bioenrichment/biodepletion, early warning signals and 'hot spots' of the Indian biota in space and time. Furthermore, based on their study, they establish trends so that meaningful action can be planned for an overall ecological restoration in general, and restoration of endangered species in particular. Gone is the time when the members of the five kingdoms (Monera, Protista, Fungi, Animalia and Plantae) occupying a common habitat and existing as in interacting system are treated as bits and pieces. One cannot delink a flowering plant from its pollinator or mycorrhiza, a carnivore from its prey, a herbivore from herbage that it eats, above all different biota from their common habitat, and numerous other associations. There is a need to understand processes like mutualism, co-adaptation, co-evolution, predation/parasitism and competition, and speciation together with fundamental processes of mutation, recombination and natural selection leading to survival of the fittest. Equally important are the ecological processes and the role of people living harmoniously in an ecosystem, and especially the lessons to be learnt from such associations.

This does not mean that there is a need to disband the staff of the Surveys, but the need is to revitalize and establish a cadre of taxonomists who look at all biota in a given habitat as an interacting, interconnected, interrelated, interdependent and holistic system rather than as isolated bits and pieces. This would need creating a new brand of dedicated taxonomists who do not look at plants, animals and microorganisms with a dry lens and a dry mind, but as ecologic and economic entities. There will have to be specially designed and designated training centres. This has to be done even if it requires the advice and help of foreign experts and agencies. In time to come, enormous gains would accrue out of this exercise. Advanced genetics, breeding, biotechnology and pharmaceutical sciences have to be backed by advanced taxonomy, both classical and experimental.

SCIENTIFIC CORRESPONDENCE

Record of opal phytoliths and associated palynofossils from Indian crude oils

Opal phytoliths are recorded from the crude oils along with palynofossils. These indicate the Paleogene source for the Bassein crude oils of the Bombay offshore area. The phytoliths, the associated palynofossils and dominant humic organic matter suggest a terrestrial origin for the crude oils.

Five new phytoliths are recorded and described. They are grouped as oval, triangular, ellipsoidal, circular and polygonal phytoliths.

The study of crude oils is an effective tool to determine the age of source rock and source organics of these oils. It is termed as oil palynology. Different types of spores, cellular structures, cuticular structures and wood fragments have been extracted earlier from the crude oils of Digboi field of Assam, India, to find out the source of the oils[1]. Panicoid and elongate type of phytoliths have been recorded from the subsurface sediments of North Bassein Well No. A, Bombay

offshore area, and the historical background of phytolitharians has been discussed[2]. Microfossils have been extracted from the nine crude oils of Jurassic, Triassic and Permian reservoirs in Australia to explain the controversy of Permian/Jurassic origin of oil. Crude oil studies have demonstrated that the oils were derived from the Jurassic source and not from a Permian source[3]. The presence of the spore and pollen assemblages in hydrocarbons from southern Israel indicates a common generation and migration in all the sampled oils[4]. It is concluded that the study of crude oils plays an important role in investigating the age of source rock and the time of migration of the hydrocarbons. The palynological assemblages have also been recorded from the crude oils of the buried hills of China[5]. They discussed the dating of the source bed, oil and gas migration and oil source in the paper.

Kolbe[6] suggests that the better oil sources have better number of fossils in the crude oil and *vice versa.*

The opal phytoliths and other palynofossils were recorded from three crude oils. The crude oils A, B and C were obtained from BA-A, BA-B and BA-C wells, respectively. The wells are located on south Bassein structure of the Bombay offshore area (Figure 1). The crude oils were diluted by using suitable solvents. Then the residual matter was recovered by sieving the solution through a 8–10 μm sieve. The solution was again centrifuged on higher RPM for the recovery of macerate. The solvents used were: xylene (hot/cold), chloroform, petroleum ether and absolute alcohol. The recovery of the macerate was meagre. Permanent slides were prepared by the usual palynological technique and examined under the Leitz microscope using oil immersion objectives.

The main objective of the study was to record phytoliths; however, it also yielded palynofossils, organic matter and other organic remains. The slides are deposited in the repository of Palynology Laboratory, KDMIPE, ONGC Ltd., Dehradun, numbered as IPE/PALY/93/OILA(1-3), OILB(1-4), OILC(1-5).

Phytoliths are the silicified casts of epidermal cells of terrestrial plants, mainly grasses[6,7]. Indian corn produces several morphotypes of panicoid and elongate phytoliths[8]. Subsequently, these microscopic bodies of opaline silica, are seen in seeds, fruits and bracts of many families of angiospermous higher plants of tropical climate. The role of phytoliths is increasing tremendously for providing an independent source of palaeoecological interpretation. They have limited biostratigraphic values[9,10].

The nomenclature of the phytoliths is unsettled; however, five classes have been proposed in the literature[11,12]. They are

grouped as follows: (1) festucoid, (2) chloridoid, (3) panicoid, (4) elongate, (5) agrostoid and (6) nardoid. Out of these six phytoliths only panicoid-type were observed in the present study. The distribution of phytoliths and the associated palynofossils is shown in Table 1. Five new types of phytoliths and the panicoid phytolith are illustrated in Figure 2. A brief morphological description of these new groups of phytoliths and their occurrence is presented below.

Oval phytolith (Figure 2, Plates 7, 12). Description: shape oval; inner body thick, prominent and having size 12.5 µm; 1.3 µm long spinous projections at the periphery; outer opaline surface 2.5 µm and the overall size 16–22.5 µm. Occurrence: crude oils A and C.

Triangular phytolith (Figure 2, Plate 10). Description: shape triangular; inner body prominent having maximum length 34 µm; 4–5 small projections of about 0.5 µm at the periphery of the inner body; outer opaline surface smooth and 2 µm thick; overall longer side 36 µm and smaller side 25 µm. Occurrence: crude oil A.

Ellipsoidal phytolith (Figure 2, Plates 9, 16, 19, 20, 23–25). Description: shape ellipsoidal; inner body prominent and ranging in size from 20 to 75 µm; numerous projections of 2.5–3.8 µm size seen at the periphery and on the surface of the inner body; outer opaline surface smooth and the overall size 31–80 µm. Occurrence: crude oils A, B and C.

Circular phytolith (Figure 2, Plates 8, 11, 13). Description: shape more or less circular; inner body thick and prominent size 18 µm; 8–22 small-sized projections of about 0.5 µm protruding from the peripheral surface of the inner body; outer opaline surface smooth and ranging in size from 22.5 to 25 µm. Occurrence: crude oils A and C.

Polygonal phytolith (Figure 2, Plates 14, 15, 26). Description: It has 5–6 sides in the outer surface. Inner body thick and prominent; maximum size of the inner body in the range 20–37 µm; 10–16 projections of 1–3.5 µm size seen at the periphery of the inner body of phytoliths; the two sides of the outer surface at junction are projecting; overall size including projections is in the range of 29–45 µm. Occurrence: crude oils B and C.

Palynofossils. Palynofossils are documented from crude oil. The distribution is shown in Table 1 and illustrated in Figure 2. Trilete spore (Plate 1, 2); *Proteacidites* sp. (Plate 6); *Polyvestibulopollenites* sp. (Plate 5); *Palmaepollenites* sp. (Plate 4); fungal spore (Plate 3).

Organic matter. Humic organic matter is present in all the three crude oils. It has not been illustrated.

Other assemblages. Collenchymatous plant cells, common (Figure 2, Plates 18, 22, 27, 28); sclereids with projections, rare (Plate 29) and lignified trichomes, rare (Plate 30). For distribution see Table 1.

The assemblages of phytoliths and palynofossils are diversified in crude oils A and C as compared to crude oil B (Table 1). A common to good percentage (30%) of phytoliths in crude oils indicates probably one genesis for these studied crude oils. The organic matter yield is dominated by humic facies (40%). The frequency and diversity of palynofossil is comparatively low (15%). The presence of palynofossils *Proteacidites* sp., *Polyvestibulopollenites* sp. and *Palmaepollenites* sp. suggests that crude oils are derived from Paleogene source rocks of terrestrial nature, which are mainly shales. It indicates a wide age range. The dating is tentative due to the paucity of data. Other assemblages constitute 5% and organic matter of sapropelic nature is about 10%. The main reservoir rock in the basin is the limestone of the Miocene age. The constituents in the crude oils are dominated by phytoliths and humic organic matter and show rare occurrence of other palynofossils.

The study is based on the occurrence of phytoliths and palynofossil assemblage. About thirty per cent of variously shaped opal phytoliths are recorded in the crude oils of the three wells, indicating terrestrial origin for all the three crude oils. The combined presence of the opal phytolith, humic organic matter, palynofossils and other terrestrial forms shows that the crude oils A, B, and C are terrestrially sourced of Palaeogene age.

Five new groups of phytoliths, viz. oval, triangular, ellipsoidal, circular and pentagonal phytoliths, were recorded from the crude oils of Bombay Offshore Basin, India.

Massif-type anorthosite near Ayialur, Dindigul, Anna District, Tamil Nadu, South India

A new anorthosite mass is found as differentiated massif pluton near Ayialur, Dindigul Anna District, Tamil Nadu (longitude between 78°6′ and 78°9′ and latitude between 10°32′ and 10°35′). The massif-type anorthosite mass shows fine-grained border gabbroic facies to coarse-grained anorthosite core through medium-grained gabbroic anorthosite and anorthositic gabbros. The anorthosite mass exhibits foliated fabric in marginal zones with even-grained, granular fabric in core. Ilmeno–magnetite–pryoxenite rocks occur as thin layers in association with anorthosites.

The area is composed of metasediments including metaquartzite, quartz schists, biotite gneiss, amphibolites and calc gneisses. The trends of metasediments reveal two generations of folds with E–W axial trend plunging to the west and NNE–SSW trend plunging to the north.

The anorthosite massif-type body found emplaced as a dome-like mass occupies the antiformal cross-folded structure in the midst of quartzites. It is encircled and caped by metaquartzites and quartz schists. The quartzites trend in ENE–WSW through NE–SW to NW–SE directions, indicating two periods of folding generated in the area.

Petrography

Anorthosites and related rocks are coarse- to fine-grained leucocratic to melanocratic rocks. Anorthosite is chiefly composed of labradorite with subordinate hornblende. Gabbroic anorthosite and fine-grained gabbro contain diopsidic pyroxene. Common accessories are opaques (magnetite + ilmenite) and zircon. There is a general variation in the relative proportion of mafics and felsics from anothosites to gabbros.

Table 1. Estimated modal composition of the anorthosites and related rocks

	Anorthosite	Gabbroic anorthosite	Anorthositic gabbro	Fine grained gabbro
Plagioclase (labradorite)	95.00	78.00	65.00	55.00
Hornblende	3.50	16.50	25.00	30.00
Diopside (relict and discrete phases)	—	3.20	6.50	10.50
Ores (magnetite, ilmenite)	1.50	2.30	3.50	4.50
	100.00	100.00	100.00	100.00

The estimated modal compositions of the anorthosites and related rocks are shown in Table 1. The data show a close agreement with Buddington's classification of anorthositic rocks of Adirondack[1] and Kadavur anorthosites[2].

A technique for axenic culture of *Puccinia romagnoliana* – A potential bioherbicide for purple nutsedge

Purple nutsedge (*Cyperus rotundus* L.) is the most troublesome weed in all agricultural production areas of the world having a large vegetative growth capacity through underground tubers. None of the control measures available against this weed are efficient as well as economical. A rust caused by *Puccinia romagnoliana* Maire and Sacc. has been reported for its possible use as biocontrol agent of the nutsedge[1]. Observations with this rust showed significant reduction in tuber number and tuber weight by 34 and 83%, respectively[2]. However, rust being an obligate pathogen, success of developing it into biological control agent depends on many factors, the foremost being the ability to produce abundant inoculum for storage and application in the field. Keeping this in view, an attempt was made to develop axenic culture of *P. romagnoliana*. Different culture media were tested and for the first time a technique has been developed to culture this rust on artificial growth medium.

The leaves of *C. rotundus* were inoculated with rust uredospore suspension,

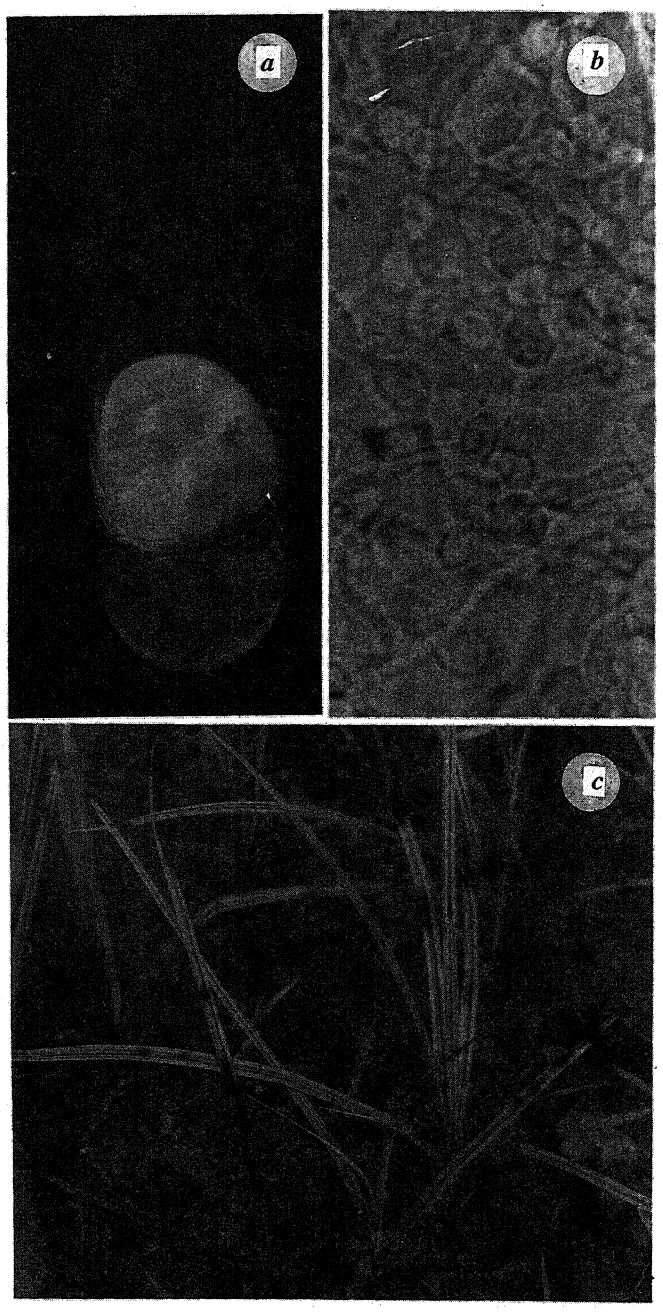

Figure 1 *a–c*. *a*, Axenic culture of *P. romagnoliana* on supplemented MS medium; *b*, Chlamydospore formation of *P. romagnoliana* in culture (225 ×); *c*, Necrotic lesions development on *C. rotundus* leaves after artificial inoculation with chlamydospores of *P. romagnoliana*.

Table 1. Effect of temperature on mycelial growth and chlamydospore formation of *P. romagnoliana*

covered with wet polythene bags for 48 h to provide high relative humidity and incubated at room temperature (approx. 30°C). Olive brown necrotic, nonsporulating lesions were seen to develop in 15–20 days. These lesions were cut into small bits 5–10 mm, surface-sterilized with 0.1% $HgCl_2$ for 2 min, rinsed thrice with sterilized water and plated on MS basal medium[3] (pH 5.8) in petri plates. The medium was supplemented with 2 ppm 2,4-D and 0.5 ppm kinetin. The plates were incubated at 26 ± 1°C. The mycelial growth started in 48 h. A thick stroma of fungus developed on the medium in 5–6 days (Figure 1 *a*). The colony was white in colour, raised and wrinkled and did not penetrate the medium. The cleavage of protoplast and formation of chlamydospores started after 3 days and abundant spores were formed in 10–15 days (Figure 1 *b*). The chlamydospores were initially hyaline, thin-walled but became dark brown and thick-walled in 25–30 days.

Fungus growth and spore formation were studied at different temperatures, viz. 20, 25, 30 and 35°C. Four mm diameter mycelial discs of 10-day-old culture were plated on supplemented MS-basal medium in petri plates and incubated at different temperatures. Maximum mycelial growth was at 20°C (Table 1), whereas at 35°C it was negligible. Chlamydospore formation started after 3 days of incubation at 25°C and after 4 days at other temperatures. Maximum spores, per unit area of mycelial mat, were formed after 14 days at 25°C; although at 35°C it was after 9 days, the mycelial growth forming chlamydospores was very scanty at this temperature.

Plants of *C. rotundus* were artificially inoculated with the chlamydospores obtained in culture. The leaves were rubbed with a wet cotton swab to remove the wax layer, sprayed with chlamydospore suspension, covered with wet polythene bags for 48 h and incubated in isolation under natural conditions (temperature approx. 30°C). Yellow necrotic spots started appearing after 15–20 days which later turned dark brown and necrotic (Figure 1 *c*). These symptoms were similar to the ones from which the fungus was originally isolated and were also observed in naturally infected plants in the field. Reisolations from these spots yielded the same fungus. *P. romagnoliana* significantly reduced the growth of *C. rotundus*.

With the development of axenic culture of *P. romagnoliana* on hormone-supplemented MS medium, one major obstacle in its development as a biocontrol agent against purple nutsedge has been overcome. Although mycelial growth and sporulation are better at 20 and 35°C, respectively, the objective of this study was to obtain maximum sporulation in minimum time. For this, 25°C is the optimum temperature. Further studies are needed to standardize the application technology of this axenic culture.

Polyphenolic components of flowers of *Helichrysum bracteatum*

Helichrysum bracteatum (Asteraceae) is a stout annual herb, naturalized in high altitudes. It is commonly available in the Nilgiris and Kodaikanal hills of south India[1]. The flowers are large, everlasting and appearing in golden yellow, pink and ivory white shades. *Helichrysum* species are rich in secondary metabolites and have good medicinal value[2]. Previous reports reveal that *H. bracteatum* contains lignin and aurones[3,4]. There is no record of isolation of any other constituent. In view of the reported medicinal values of *Helichrysum* species, three differently coloured (golden yellow, pink, ivory white) flowers were examined for their polyphenolics.

Fresh flowers of *H. bracteatum* var. *bracteatum* collected from the Nilgiris hills in south India were refluxed with 90% boiling ethanol and concentrated under reduced pressure. The aqueous crude extract was fractionated into benzene, ether and ethyl acetate solubles. Ether and ethyl acetate soluble fractions tested positive for polyphenolics. These fractions were mixed together, concentrated and kept in an ice chest, where they gave a yellow solid, which on PC and TLC indicated the presence of UV-active compounds. Separation was carried out by preparative cellulose TLC[5] with 50% acetic acid as the developing solvent. The separated zones were eluted with hot methanol and the residue recrystallized from MeOH. The compounds characterized[6] and the methods[7] used are given in Table 1.

^{1}H NMR spectral data (400 MHz, $CDCl_3/CD_3OD$, TMS as int. std., δ, ppm) for the two rare flavonoids showed the following characteristic signals: Bractein: 6.71 (s, 2H, H-2′,6′), 6.31 (s, 1H, =CH–), 6.04 (d, J = 2 Hz, 1H, H-7), 5.98 (d, J = 2 Hz, 1H, H-5), 4.66 (d, J = 8 Hz, 1H, anomeric glucose proton), 3.65–3.17 (m, 6H, other glucose protons); cernuoside: 7.22 (d, J = 2 Hz, 1H, H-2′), 6.98 (dd, J = 8,2 Hz, 1H, H-6′), 6.60 (d, J = 8 Hz, 1H, H-5′), 6.42 (s, 1H, =CH–), 6.09 (s, 1H, H-7), 6.02 (s, 1H, H-5), 4.68 (d, J = 8 Hz, 1H, anomeric glucose proton), 3.68–3.19 (m, 6H, other glucose protons). A survey of the distribution flavonoids in Asteraceae reveals the predominance of apigenin and luteolin along with their 7-glucosides[8]. The present finding of luteolin and its 7-glucoside is in further support. The co-occurrence of phenylpropanoid, aurones and flavonoids in *H. bracteatum* is in agreement with the biogenesis of these types of compounds involving common precursors like mevalonic acid, shikimic acid and phenylalanine. The present study revealed that three morphologically similar varieties of *H. bracteatum*, differing only in the colour of the flower, biosynthesize three different flavonoid compounds – aurone glycosides and flavone in golden yellow, aurone glycosides, and flavone O and C-glycosides in pink and flavone-O-glycoside in ivory white and thus correspond to three chemotypes differentiated by chemical constituents. Bractein was screened for anti-cancer and anti-HIV properties with the help of

MEETINGS/SYMPOSIA/SEMINARS

1995 Society for Industrial and Applied Mathematics (SIAM) Annual Meeting

Place: Adam's Mark Hotel
Charlotte, North Carolina
Date: 23–26 October 1995

Meeting themes include: Computational science and engineering, Education-CSE Degree Programs, Multidisciplinary design optimization, Computational biology, Control of large systems, Numerical algorithms, Numerical software, Environmental modelling.

Contact: Society for Industrial and Applied Mathematics
3600, University City Science Centre
Philadelphia, PA 19104–2688
Phone: 215-382-9800
Fax: 215-386-7999
e.mail: meeting@siam.org

Institution of Chemists (India): Associateship Examination, 1996

The Associateship Examination of the Institution of Chemists (India) will be held in November 1996. The last date for registration is 30 November 1995. For further enquiries regarding this and for Membership:

Reviving experimental physics in the universities – The IUC initiative

S. Ramaseshan

*There is widespread concern about the state and future of science in the universities – witness the recent presentation and discussion of the National Science University (NSU) proposal in these pages. One of the measures taken by the University Grants Commission (UGC) to provide improved opportunities for research level work in the university sector is the creation of several Inter-University Centres where unique facilities are shared by workers from all over the country. The Inter-University Centre for Astronomy and Astrophysics (IUCAA) is an example and a brief report by J. V. Narlikar appeared in Current Science some time ago (1993, **65**, 730). The author of this article recently visited the Inter-University Centre for DAE facilities (IUC-DAEF) located on the university campus in Indore and was struck, as many others before him have been, by the many unique features of this institution, where a serious effort is being made to revive first-rate experimental condensed-matter physics in the universities, in a quiet, low-key, low-publicity style. The following sections on the origin of this institution and its facilities and activities have been compiled based on detailed information kindly provided by the staff at IUC-DAEF.*

Origin of IUC-DAEF

It is undeniable that experimental research in physics in universities in India, barring a few notable exceptions, is in very dire straits today. Condensed-matter physics is an area in which experimental work of reasonable quality can be pursued by small teams with not too expensive equipment. Though the majority of the existing universities do pursue research in condensed-matter physics, facilities for characterization of the materials prepared and for carrying out a reasonably complete range of experiments on materials at different temperatures are very often not available to most researchers. This means that the standard of the research as well as the stimulation that it offers to students and faculty at the university both suffer.

On the other hand, first-rate experimental facilities are often established outside the university system. For example, DAE has built a variety of neutron spectrometers on the Dhruva reactor. Protons, deuterons and alpha particles can be accelerated to several MeV energies with the Variable-Energy Cyclotron in Calcutta (VECC). There are plans to build a superconducting cyclotron. The Centre for Advanced Technology (CAT) in Indore is developing synchrotron radiation sources Indus 1 and Indus 2. It was felt both in the DAE and outside that these frontline research facilities must be available to university scientists. University scientists must be slowly inducted to work with scientists from DAE in developing different types of accelerators, beamlines, etc. One can add that elsewhere in the world this kind of university participation is a rule rather than an exception. The Very Large Array Telescope, which in many senses the world's most powerful radio telescope, is even run by an association of universities, and many accelerators like CERN have large teams of university researchers building and using giant detectors.

Aims

To improve the quality of experimental research in physics in universities and to provide access to the major DAE facilities to the researchers from universities, the UGC set up the Inter-University Consortium for DAE Facilities (IUC-DAEF) in 1990. This is an autonomous society fully funded by UGC. IUC-DAEF has three centres, at Bombay, Calcutta and Indore, the last one being the headquarters.

The IUC-DAEF supports projects from university researchers to use the major national DAE facilities at BARC and VECC and also the upcoming DAE facilities at CAT. To make the best use of these expensive facilities, it is necessary to work with well-prepared and characterized materials and to carry out other experiments which will be complementary to those obtained with the major DAE facilities such as the neutron

S. Ramaseshan is in the Raman Research Institute, Bangalore 560 080, India.

spectrometers at BARC or cyclotron at VECC. Therefore, the IUC-DAEF has the task of setting up supporting facilities. The IUC-DAEF also participates in certain development projects of DAE. Periodic workshops on current topics of research for the benefit of young faculty and research scholars of universities are another important activity.

Utilization of DAE facilities

In the last four years the number of university projects on the Dhruva reactor at BARC has increased to 30. There is a steady stream of university scientists visiting BARC for carrying out experiments with the neutron spectrometers. The majority of the projects use the profile analysis powder diffractometer, the small-angle neutron scattering spectrometer, the high-Q diffractometer for the study of amorphous materials and the neutron spectrometers for magnetic studies, in that order. The SANS (small-angle neutron scattering) spectrometer is being used by chemists from different universities. The IUC-Bombay centre conducts each year in association with BARC scientists a three-week workshop in which about 20–25 scientists from universities and other institutions participate. Two weeks are devoted to lectures on various aspects of neutron scattering and diffraction. In each workshop one aspect of neutron scattering is emphasized. During the discussions that follow the lectures and tutorials, the participants are encouraged to come out with ideas for projects. In the third week of the workshop the participants are taken to BARC so that they can see actual demonstrations of the different spectrometers. This method of generating proposals has proved effective. The proposals are often prepared after a detailed discussion between the investigator from the university and the scientists from BARC. Every year the progress in a project is reviewed at a Project review meeting at which all project investigators and scientists from the Solid-State Division of BARC are present. From 1992–1994 ten papers have been published in journals on results obtained in these projects. The number of presentations at the annual DAE symposium on solid-state physics is 20. Till recently K. R. Rao and P. R. Vijayaraghavan, with the cooperation of their colleagues in the Solid-State Physics Division of BARC, were looking after the administrative and scientific aspects of these projects. Dhananjai Pandey joined as the Centre Director of the IUC-Bombay Centre in the middle of 1994.

In Calcutta, activities started from February 1992, when S. N. Chintalpudi was appointed the Centre Director. There are now 32 projects on the Variable-Energy Cyclotron, including projects in nuclear physics, materials science, chemistry and biology. These projects are also reviewed each year. Seven publications have appeared in international journals and eleven papers have been presented at national symposia so far. Discussion meetings on pre-equilibrium phenomena and in-beam γ-ray spectroscopy have been held to evolve group projects.

Starting from 1993, seven projects were sanctioned on the low-energy accelerators at IGCAR, Kalpakkam. This was done after holding a workshop on the type of experiments that can be done with low-energy accelerators. The projects were reviewed in November 1994. Students from different universities have stayed for extended periods in Kalpakkam and have helped in setting up the various beamlines on the accelerators, and it is expected that useful scientific results will soon be forthcoming.

IUC Indore

The Indore Centre started in July 1990 with V. G. Bhide in charge and R. Srinivasan took over the Directorship in December 1990. This Centre, which is also the headquarters, has independent materials preparation and characterization facilities as well as supporting facilities of EXAFS, ESCA, soft-X-ray spectroscopy, transport properties and AC susceptibility measurements, etc. The centre is involved in developing beamlines for synchrotron radiation for users from universities. One current project is to build a beamline for photoelectron spectroscopy (PES) on Indus 1. The wavelength range in which this PES beamline will work is from 60 to 1600 Å. After an evaluation of the various types of gratings, mountings, etc., it was decided to use a toroidal grating monochromator with three interchangeable gratings to cover this wavelength range. To get adequate resolution for PES work the TGM 2600 design of Bessy has been chosen. The toroidal grating monochromator has been purchased from Jobin Yvon in France and the turbo and sputter ion pumps were attached to it, and ultra high vacuum achieved. The grating has been aligned and the expected resolution checked with He I and He II sources. The design for the mirror chambers, the laser alignment chambers, etc., have been made by scientists from IUC. These are under fabrication. It is expected that the entire beamline, which will be 12.1 m in length, will be assembled and tested by December 1995 in conformity with the expected time schedule of completion of Indus 1. To carry out some basic photoelectron spectroscopy experiments the IUC-DAEF has given a project to D. D. Sarma and M. S. Hegde of IISc, Bangalore, to construct a set-up consisting of a sample preparation chamber, sample analysis chamber, and analyser with provision for putting a twin X-ray anode and a He UV source. This spectrometer has been constructed and is being assembled.

With this beamline one can study the core level

spectroscopy of K levels of light elements, L levels of elements of medium atomic weight and M levels of heavy elements. A discussion meeting on the type of projects to be undertaken has been held in Indore.

The second major project is to build a complete soft-X-ray system to study transmission and reflection of thin films at different angles of incidence. This is of interest from the point of view of mirror coatings for the synchrotron radiation source. This project is partially supported by DST. In this project the rotating magnetic seal with an aluminium anode has been imported from Rigaku and the filament assembly, the vacuum chamber and the power supply have been built locally. It is designed to operate at 3 kW. The soft-X-ray continuous radiation coming out of the rotating anode source will be monochromatized with a double crystal monochromator with a fixed entrance and exit slit. Such a monochromator operated by a single screw driven by a DC motor has been designed and fabricated with a positioning accuracy of 5 μm. The large d spacing crystals have been imported. The channeltron detector has been imported and successfully tested. The experimental chamber with $\theta - 2\theta$ mount is currently being fabricated. The whole system will be operational by October 1995.

Materials preparation and characterization

The IUC-Indore centre has set up materials preparation, characterization and measurement facilities listed below:

1. An EXAFS (extended X-ray absorption fine structure) spectrometer with the mechanical movements designed in Pune University and built by a company there. This is a bent-crystal Johansson-type spectrometer using a Si crystal. This spectrometer is mounted on one window of a 12 kW rotating anode X-ray generator. Since the generator has Cu and Co anodes, EXAFS for elements whose absorption edges fall in the appropriate wavelength range can be carried out. This instrument has been used to study the EXAFS of copper-containing organic complexes, copper-containing chalcogenide glasses, As–Se glasses and glassy bismuth copper oxide materials. Users are from universities, IITs and the IISc.

2. A powder diffractometer mounted on the second window of the Rigaku rotating-anode generator. This is equipped for use at temperatures varying from 80 to 1000 K and allows grain size determination, strain determination, etc. This has been widely used by several university groups to characterize their samples. Last year nearly 500 diffractograms at different temperatures were taken for university users.

3. An ESCA unit from VSW, UK, has been functioning for the last three years. This has provision for XPS with a twin-anode source, UPS (ultraviolet photoemission spectroscopy) with He I and II light source and an electron gun for Auger spectroscopy. There were several problems with this instrument, but all the problems have been solved with the expertise available in Indore. This facility has been availed of by nearly 15 university users so far, mainly for core-level spectroscopy work. It is planned to improve the facility by providing a scraper unit, a variable-temperature attachment and a high-energy Argon ion gun for depth profiling.

Facilities developed in-house

4. A fully automated AC susceptibility set-up with variable temperature in the range 80–300 K and with provision for recording the in-phase and 90° out-of-phase components up to the seventh harmonic. With this, studies have been made on the AC susceptibility of sintered pellets of high-T_c materials. The set-up can be used to study magnetic ordering and the growth of harmonics close to the ordering temperature.

5. An automated low-frequency AC conductivity set-up with a precision of 1 part in 10^5 with temperature control to 0.1 K in the range 80–300 K.

6. A dielectric constant and loss set-up to work in the temperature range 80–600 K and in the frequency range 10–13 MHz. This is being automated.

7. A low-temperature resistivity set-up built on a closed-circuit refrigerator. The resistivity of three (metallic or semiconducting) samples can be measured at the same time with temperature controlled to 10 mK in the range 15–300 K.

8. A low-temperature thermopower set-up mounted on a closed-circuit refrigerator and automated to operate between 15 and 300 K. The thermo-emf can be measured to a precision of 0.1 μV. A set-up for high-temperature thermo-emf measurement is available. A provision for evacuating the sample chamber and filling it with an inert gas needs to be made.

9. A vibrating-reed set-up for measuring internal friction and elastic constant is working and has been automated.

10. An adiabatic pulse calorimeter has been set up and automated to work in the range 80–300 K. This requires samples of 0.5 g to set a good accuracy.

Very soon the temperature range in which the above facilities will be operational will be extended to 4.2 K with cryostats fabricated by a Madras firm.

In addition, there is a ball mill, temperature-controlled resistive furnaces, and an arc furnace for preparation of samples. A thin-film coating unit is also available.

Nearly 60 groups from various universities, IITs and IISc have used the facilities in the last two years.

Low-temperature facility

The entire low-temperature facility for production of cryogens has been set up using second-hand machines obtained as gift from IIT, Madras, the Free University, Berlin, and the Max-Planck Institute for Solid-State Research in Stuttgart. A 25-year-old nitrogen plant obtained as a gift from IIT, Madras, has been installed and has produced in the last two years 8000 l of LN_2. An old helium plant obtained from Free University, Berlin, was commissioned in May 1994 and is working satisfactorily. The IUC has supplied liquid helium to NCL, Pune, twice (60 + 70 l).

In Calcutta facilities have been set up for making targets for users of the cyclotron and many university groups have used these facilities. Temperature-controlled diffusion furnaces for making Si(Li) detectors have been set up and some detectors made. Their performance is being evaluated. Several NIM electronic modules are made available for users of the VECC. A Mössbauer spectrometer has been commissioned and is being regularly used by scientists from different institutions around Calcutta. A positron annihilation set-up and a time differential perturbed angular correlation set-up are being established with the help of several university groups. Laboratories for radiochemistry, general chemistry and toxic chemistry have been set up. Attempts to prepare Mössbauer and positron sources are underway.

The three centres together have conducted nearly 30 workshops/discussion meetings/national symposia in the last four years. More than 700 research scholars and scientists from universities and other research institutions drawn from most of the states of the country have participated in these workshops.

Some special features

Even the rather bald factual account of IUC-DAEF activities given above is impressive, given the short time that it has been in existence. But visitors to the Indore Centre quickly learnt that this is only a part of the story. The way in which the centre was built up and is being run has some special features which may be of wider interest. One important aspect was that even before the main building was complete, the first laboratory activities had started. The recruitment was carried out in a phased manner, so that everyone who joined had plenty of work to do. This situation prevails even at present, and is in healthy contrast to others, alas not uncommon in our country, when a large building and recruitment programme precedes active research. It also appears that the administration is small in size, uses modern means of communication, and is charged with helping the scientists procure what they need with the minimum possible delay. The scientists themselves can devote up to 30% of the time to their own research, which is of course a good incentive to keep the equipment in good condition. This is a lesson for those who would set up pure 'facilities' and appoint people to do only routine work. At the same time, the opposite situation of the facilities being all used in-house, with only lip service to outside users, can also arise! There seems to be no risk of this at IUC at present – if anything, it was clear that enormous effort was being put in to see that the university users went away with the data they wanted. Another important point is the presence of IUC's own research students, who, like the staff, are enthusiastic about their work and spend long hours in the laboratories. Many years ago, C. V. Raman described some of our laboratories as 'graveyards of scientific equipment'. The sight of so much equipment well maintained *and fully utilized* would have warmed his heart. It should be mentioned that there is a strong emphasis on the workshop and on fabrication of many things in-house. *The entire low-temperature facility is based on equipment which had been discarded elsewhere.* By making it work, the staff at IUC have earned the right to ask for new equipment in a manner which is again not common elsewhere!

What of the future?

While the achievements of IUC are laudable, one should also utter a word of caution. By providing such ready-made facilities, one may be depriving the researcher from learning to do good experiments himself. In such a case the IUC will not be promoting the growth of expertise in experimental physics. Perhaps the IUC should think of organizing experimental courses for two to three weeks whereby young scientists are made to handle equipment and do their experiments themselves. This may not be easy because it would mean setting up a duplicate set of less expensive facilities for handling by the students and may cost money. But if the culture of doing good experiments is to grow, the UGC *must* find money for such a programme.

The IUC with its expertise must try to involve young students in designing equipment and, if such designs are successful, it must find a way of involving small-scale industry in fabricating and selling such equipment. Unless we try to make our own equipment, Indian science will be captive.

The workshops organized by IUC have generally been well received. IUC pays for the travel and boarding of the participants. Possibly due to financial constraints, too much is attempted to be covered in too short a time and enough reading material is not given to the participants. Also, due to lack of guest house facilities it has not been possible to put the participants and speakers together. This can hinder the development of interactive participation. A guest-house with a sufficient

number of rooms seems to be an essential requirement. If IUC could restrict the topics to be covered and make the lectures truly pedagogical, the purpose of organizing such workshops will be served better.

IUC should put some effort in improving the laboratory curriculum of B Sc and M Sc classes. It is involved in one such education project which is restricted to five colleges of Madhya Pradesh. The project has just started. It will be interesting to watch how this project succeeds.

Finally, it may not be inappropriate to caution IUC about the dangers of doing too many things in too short a time. IUC must now consolidate the gains it has achieved so far. The experiment of getting university people to work together is alien to our prevailing culture. Hence, one must wait for sufficient time for the idea to take root. Sometimes pushing an idea too fast may generate an adverse reaction!

The success of any venture depends on the initiative and dedication of the leadership. IUC has been lucky in that the first two directors have shown qualities of dedication and purposeful action. To nurture IUC, which is a young plant today, into a spreading tree tomorrow with well-entrenched roots, great care must be taken in selecting the next Director of IUC-DAEF. He must be an experimental physicist of repute and must command the respect of the physics community as a whole. He must be deeply committed to the cause of providing service to the university community and to strengthening the bonds between the scientists of DAE and the universities. He must have administrative competence and should keep in check the universal, ever-present tendency for the growth of red-tapism in any organization. It is to be hoped that the IUC-DAEF will be fortunate in having a succession of such leaders.

Modern science and technology: The public perception

V. Govindarajulu

Positive public perception and attitude towards modern science and technology (S&T) is a vital link in the all-round economic, industrial and cultural development of a nation. Public hostility and/or indifference towards modern S&T, on the other hand, is a drag on the growth of economic productivity of any nation. Public policy options, as derivatives of public perceptions, can be the basis for formulating effective and productive development programmes. The results of this DELPHI study, conducted in the State of Kerala, highlights the public perceptions and attitudes towards modern S&T, productivity and industrial development. The public in the State of Kerala possesses a positive and desirable perception that modern S&T is the key to productivity and national development. The results are comparable to the studies done elsewhere and, therefore, universally valid. This study provides a broad spectrum of philosophical and sociological foundations of modern S&T and industrial development. In-depth areawise, sectorwise and disciplinewise impact assessment studies are required before initiating large-scale investment-oriented S&T projects in the states and in the country.

SCIENCE and technology (S&T), nowadays, plays a vital role in the daily routines of our lives. Industrial development, economic productivity and thus national prosperity depend much on the vital role played by S&T. Efficiency and productivity of our nation's economy are functions of social technology of the people. Social technology is the level of knowledge base, entrepreneurship and social consciousness acquired by the people, that continuously helps them to raise the quality output of goods and services per given quantum of resources as input. The gross domestic product (GDP) per capita or per capita income at any given time is the index of the level of social technology of the people and their economic productivity attained. Thus, per capita income of some Asian countries – in 1993, for example, Japan

V. Govindarajulu is in the Regional Research Laboratory, Industrial Estate P.O., Trivandrum 695 019, India.

$ 23,800, Singapore $ 10,450, Taiwan $ 8500, Malaysia $ 2160, China $ 650, India $ 340 – indicates their level of economic productivity, social technology, entrepreneurship, social consciousness and public perception and attitude towards modern S&T. Accordingly, public hostility and/or indifference to S&T is an insurmountable hurdle to nation's economic and industrial development. The economics of underdevelopment and the politics of communalism, which sustain each other, are the characteristics of stagnant and/or low productive economy. And when they are reinforced by the hostile and/or indifferent public perception and attitude towards modern S&T, they lead the country to a negative entropic decline as seen nowadays. On the other hand, the economics of development and the politics of democratic secularism, which are complementary to each other, are the characteristics of increasing orders of productive economy. And when reinforced by a positive public perception and attitude towards modern S&T, they lead the country to a positive entropic growth. One could infer such an all-round growth in the early stages of many civilizations. Therefore, a positive public perception and attitude towards modern S&T is imperative for shaping more effective public policy options[1]. Such effective S&T and public policy options could make powerful guidelines for action plans and accelerated growth of national economy.

Scope and objective

We have initiated this research project to assess and map out public perceptions and attitudes towards modern S&T by DELPHI study in Kerala and help the development agencies in the state(s) and in the country to harmonize various group interests by a process of reconciliation, while implementing large-scale investment-oriented S&T projects.

Methodology

The methods adopted here to assess and map out the public perception are: DELPHI study, i.e. seeking intuitive views of the concerned public, statistical aggregate analysis of the data received and cross-comparison and correlation with similar studies. A structured questionnaire was prepared and circulated to as many as 3000 volunteers in Kerala drawn at random and a 10% response was received, which is considered to be fairly good.

Though many participants were from in and around Trivandrum district, they were the people representing all parts of the state and the country with wide exposure to world developments. Hence, the study results could represent the public perception of the state as well as of the nation. The presentation, made here in two parts, follows a pattern of stating general principles, followed by public perception and attitude as assessed, and then is concluded by derived public policy options as guidelines for future action plans. Part 1 deals with public perception on modern S&T and economy while Part 2 deals with people's perception and attitude towards development issues and action plans.

The respondents

The public who responded to this DELPHI study were the volunteers with tremendous enthusiasm in the social function of S&T. About 88% are males and the rest females. The participants to this study were aged between 20 and 60 years, of which 38% belonged to the age group 40–49 years, followed by 26% in the age group of 30–39 years, 20% in the age group of 20–29 years, 14% in the age group of 50–59 years and 2% in the age group of 60 years and above. Majority of the respondents (56%) were postgraduates, followed by 28% doctoral, 10% graduates and 6% undergraduates. Currently, 44% of the participants are engaged in scientific research, followed by 18% in engineering, 12% in government bureaucracy, 10% in teaching, 4% in management and 12% in other professions.

Part 1: Modern S&T and economy

Given the freedom: The choice of profession

Given the freedom, the respondents would like to accord first ranking (R1) to scientific research as choice of their career and profession, followed by teaching (R2), engineering (R3), social services (R3), journalism and mass communication (R4), business and industry (R5), so on and so forth (Table 1). It indicates the occupation prestige attributed by the public to different professions and careers. Similar trends to occupation prestige, in recent studies, were also attributed by the public in China and United States[2,3]. It indicates the universal nature of occupational prestige attributed by the public.

Table 1. Given the freedom: choice of profession

First five professions	Respondents (%)	Rank accorded
Scientific research	36	1
Teaching	35	2
Engineering	12	3
Social service	12	3
Journalism and mass communication	13	4
Business and industry	25	5

World problems: Role of S&T

World develops by a process of constant struggle, unity and struggle. Constant struggle and unity are the processes of resolving contradictions that exist in nature, society and human thought, thereby raising economic productivity by many orders. These contradictions are perceived as societal problems. Recognition of such societal contradictions itself is half the solution. Therefore, it is heartening to see here that 88% of respondents to this study do recognize that the people of the world in general face innumerable problems. And 86% of them perceive that such problems do pose potential threats to ecology, environment and human habitat. An equal proportion of respondents assert that such threatening problems could provide ample opportunities to S&T and other professions in searching for feasible solutions.

When asked to rank the groups which are capable of providing more feasible solutions to such threatening problems, the majority accorded R1 to scientists (Table 2). It is followed by technologists (R2), engineers (R3), decision makers in business and industry (R4) and decision makers in the government (R5).

The ordering of ranking by the public is precise, as scientists, as a group capable of understanding the basic laws that govern the development of nature, society and human thought, technologists, as a group capable of developing viable and feasible models and systems to advance the knowledge base to the application levels, engineers, as a group capable of converting these models and systems of knowledge base on a social scale; decision makers in business and industry, as a group of social entrepreneurs converting such a knowledge base into productive investment projects, and, finally, the decision makers in the governments to put the politics in the right perspective (i.e. the art and science of making desirable things possible) to mobilize the resources of states, nation and world to convert all such societal contradictions into socially useful productive opportunities. But, as the saying goes, for every economic problem there is a political solution. That means putting politics in command but on the firm understanding of the knowledge base. Therefore, what is needed here is a mix of all disciplines commencing from all directions, each one taking lead from strengths of its own discipline and merging with strong points of others at appropriate stages.

Table 2. Groups capable of providing more feasible solutions

Groups capable of providing feasible solutions	Respondents (%)	Rank accorded
Scientists	35	1
Technologists	29	2
Engineers	34	3
Decision makers in business and industry	31	4
Decision makers in the government	21	5

S&T development: Decision by whom?

The public has given good regard to scientists, technologists and engineers. As these groups are capable of offering more feasible solutions to the world-threatening problems, the public desires scientists, technologists and engineers to take the first three places of responsibility of decision making in the process of S&T development (Table 3). It is also important to see that the bureaucrats in the governments, people in non-governmental organizations (NGOs) and industries are accorded R4th, R5th and R6th, respectively, to hold responsibilities of decision making in S&T development.

But a synthesis of roles of all the groups is necessary to obtain synergestic effects by striking harmony of interests.

S&T: People's motives

People's motives towards certain disciplines are conditioned by certain internal urges inherent to them besides the opportunities for material and spiritual gains. Accordingly, the response here is more positive and corresponds to Maslow's desirable hierarchical theory of motivation. About 48% of the respondents accord R1 to the disciplines of S&T as they give them opportunities for achieving self-accomplishment (Table 4). It is followed by social recognition (R2), excitement (R3) and security and basic needs (R4). It is a surprising but desirable response, in the present days of crisis-ridden and poverty-dominant society, where the majority of the people are generally driven by the basic and security needs. It indicates people's willingness towards self-accomplishment by advancing the knowledge base despite all-round

Table 3. Groups to hold responsibility of decision making in S&T development

Groups	Respondents (%)	Ranking
Scientists	54	1
Technologists	48	2
Engineers and professionals	44	3
Bureaucrats in the government	38	4
Others (NGOs)	16	5
Business and industrialists	14	6

Note: Multiple responses accepted.

Table 4. S&T and people's motives

Motive factors	Respondents (%)	Rank accorded
Self-accomplishment	48	1
Social recognition	38	2
Excitement	27	3
Basic needs and security	35	4

backwardness and limitations. People understand that knowledge is the source of wealth and one should advance it by all means and sacrifices. Therefore, one has to consolidate and strengthen this urge for self-accomplishment by superimposing Herzberg's two-factor hygiene theory of motivation on Maslow's desirable hierarchical theory of motivation. That is achieved by providing a conducive work environment. And such an environment will raise the economic productivity of people at par with that of advanced countries.

S&T progress: Does it benefit modern life?

Four decades back a vast majority of people in the country, particularly in the rural areas, were ignorant, suspicious and even hostile to modern S&T. One could recall such suspicions and hostilities, by the rural folk, towards vaccination to small pox. But today the scene is the reverse. Growth in literacy and awareness through mass media and cultural exchanges by travel and tourism have made all such desirable changes possible.

Accordingly, an overwhelming majority (98%) of the respondents here agree that S&T progress has immensely benefited the mankind and modern life. However, 56% of the respondents assert that such benefits extended to the whole cross-sections of the society, while 44% assert that it covered certain pockets only. Over 54% of the participants to this study assert that S&T progress has brought more of good impacts on society while 40% assert that there are both good and harmful impacts in equal proportions and 6% express nil opinion. Fortunately, none of the respondents attribute the occurrence of harmful societal impacts to S&T progress alone. Hence, the need for consolidating good impacts by weeding out bad ones by proper technology assessment and technology forecasting exercises and mass awareness campaigns. It should also be ensured that the good impacts spread to the whole spectrum of society benefiting one and all.

Societal benefits: The direct derivatives of S&T efforts

People's perception and attitude towards modern S&T is conditioned by their direct experiences with the modern amenities. Thus, public perception of societal benefits, as direct results of S&T efforts, is more realistic and positive (Table 5). About 70–80% respondents attribute to modern medical aids, better transportation and communication network, electrical domestic appliances and family planning and child birth control devices as societal benefits derived directly from the results of S&T efforts. About 50–60% respondents assert that better educational facilities, urban public utilities, declined infant mortality and better food preservation methods are other societal benefits. And 40–50% view that extended life expectancy and modern methods of recreation are direct societal benefits due to S&T progress. This is an index of people's priorities to life-styles and systems, which deserve more attention. Raise in the people's per capita income can enhance the demand for such modern amenities much beyond the present level. Accordingly, cost-effective and more productive technologies are needed to produce such quality amenities at competitive prices.

Societal harmful effects: Inherent or by-product of S&T?

Societal harmful effects, in some cases, are both inherent and by-product of S&T. The first-generation technologies, which were energy-inefficient, exhibited both the characteristics. They get intensified when disregard is given to public safety under the presumption that they do not add to the benefits. But they can be overcome by the present-generation technologies when a balance is struck between social costs and social benefits. Thus, the public expresses its concern and alarm over the present-day harmful societal effects derived as direct results of S&T efforts (Table 6). About 60–80% of the respondents assert that arms race, militarization of industrial economy and environmental pollution and ecological imbalances are the societal harmful effects resulting directly from S&T progress. Another 40–60% respondents attribute the abuse of pesticides, insecticides and chemical fertilizers and excessive dependence on medicines and abuse of drugs as

Table 5. Social benefits as direct results of S&T efforts

Societal benefits as direct results of S&T	Respondents (%) attributing
Modern medical aids	82
Better transport and communication network	78
Electrical domestic appliances	76
Family planning and child birth control devices and systems	66
Better educational facilities	62
Urban public utilities	54
Declined infant mortality	54
Better and effective food preparation and food preservation methods and systems	52
Extended life expectancy	48
Modern methods of recreation	40

Note: Multiple responses accepted.

Table 6. Societal harmful effects as direct results of S&T efforts

Societal harmful effects as direct results of S&T	Respondents (%) attributing
Arms race and militarization of industrial economy	77
Environmental pollution and ecological imbalances	66
Abuse of pesticides/insecticides/ chemical fertilizers	58
Excessive dependence on medicine and abuse of drugs	44
Food adulteration and low-quality foods	34
Degradation and withering of traditional values	26

being direct results of S&T. And 25–40% respondents believe that food adulteration, low-quality foods and degeneration and withering of traditional values are the direct results of S&T progress. Direction of S&T efforts determines its results, whose impacts can be either good or harmful. Sometimes the nature of impact can be the inherent characteristics of the type of technology itself. So what is needed is to do technology assessment and technology forcasting exercises, anticipate the nature of impacts, overcome the negative and consolidate the positives and educate the masses.

Societal problems: The root causes

Societal harmful impacts due to S&T obviously cause societal problems as well. They need to be thoroughly understood and properly tackled. Public perception here is that 38% respondents assert a few societal problems, while 34% think that some societal problems are caused by S&T progress, 6% assert most of the problems, 2% assert no problem and 6% express nil opinion. When asked to identify some such societal problems caused by S&T progress, 58% say the hampered human relationship, followed by 46% saying the environmental pollution, 27% the economic imbalances and 23% each the misuse of drugs, adverse media impacts and increased warfare.

Such societal problems and harmful effects do emerge due to the inherent contradictions that exist between the competitive but cooperative nature of the progress of productive S&T worldwide on the one hand, and the monopoly appropriation of the gains on the other. This does not permit one to give more thrust to prevent harmful effects. So, one has to resolve this contradiction by harmonizing production relations and not resist S&T progress as such.

S&T: Its substantial contributions

Public perception on certain areas in which S&T could make substantial contributions is conditioned by their direct experiences. It is more logical but a simplistic view. About 60–80% of respondents assert that S&T could make substantial contributions to certain areas such as increased production and productivity of goods and services, exploration of space, earth and ocean and optimum utilization of resources, better, fast, safe and economical means of transportation and communication and better and cost-effective child birth control methods and devices. About 50–60% respondents think that S & T could make substantial contributions in providing better, effective and economic learning systems, improving the availability of quality food, control and prevention of environmental degradation and ecological imbalances, complement labour productivity, help better understanding of the laws that govern the development of nature, society and human thought, and reduce labour intensity and substitute labour force in production of goods and services. Still there are about 30–40% respondents who think that S&T could not make any substantial contributions in reducing natural disasters, in crime control and global wars by increasing international cooperation, in promotion of global trade and promotion of democratization of society by competitive and cooperative ventures. An equal proportion of the respondents express nil opinion.

On the other hand, crime is naturally controlled when the material and knowledge base of the society is democratized. That is, when people's entitlement to material and knowledge base is enhanced according to their capabilities and contributions, a more civilized and humane society is evolved. Such an entitlement is related to compulsory and universalization of education and employment. Reduction of threats from wars, in turn, is conditioned by the globalization of capabilities through competitive and cooperative spirits. This demands for promotion of global peace, understanding, harmony and respect for human values and rights. This, in turn, is conditioned by the knowledge and material base of the world people in general.

Such interdependences and interconnections among S&T and multiple human dimensions of world people are still in the meta-physical (abstract) state of development. It is due to the widespread disparities in capabilities among the world people. Hence, the need for correcting the negative and indifferent public perceptions and attitudes by proper education and mass awareness campaigns.

S&T areas: Public funding

Public perception on public funding in S&T areas is conditioned by the objective realities of the current societal issues. The public perception correlates to the thrust of research areas the country should focus while

allocating funds. About 70–80% of respondents assert that public funding in S&T should be towards areas like improving health care and population control systems, prevention of environmental pollution, ecological imbalances and strengthening of agriculture and food. About 50–70% stress on improving education, increasing economic productivity, developing better and cost-effective means of transportation and communication, clean and reliable sources of energy, remote sensing and weather forecasting, cost-effective and ethnically adaptive housing, and exploration of space, ocean and earth for optimal use of resources. However, a large section of respondents, 20–40%, express nil opinion. Neutrality of such a large section of population towards such topical issues could often be hurdles to the initiation of large-scale S&T projects which are otherwise needed for fulfilling the basic needs of the people. And India should increase its S&T expenditure, on accelerated basis, equal to or greater than 2% of GNP or 4 times the remittances for imported technologies, to reach the threshold level of technological assimilation and diffusion capability[4].

S&T fields: India in the lead

India was one of the ancient civilizations, whose contributions to world knowledge base, since Indus Valley Civilization, are well known to all of us. India was a centre of learning which gave birth to many philosophical connotations that changed the social dimensions of many countries in Asia and elsewhere. Rise of Buddhism is one such example. Such was our tradition till the dawn of the Middle Ages of Feudalism and British Colonialism. Though there was a setback to this tradition since industrial revolution in Europe and its colonial expansion, the Indian brains still possess creative talents, which are now latent and which can blossom any time given the right fertile conditions. Thus, relatively favourable conditions in the form of vast S&T, educational and industrial infrastructure created since independence has helped India to regain the lost vigour. This is reflected in the assertion of India's S&T capabilities in many key sectors. Thus, 52% of the respondents assert that there certainly are a few S&T fields in which India is in the lead. And 10% of the respondents assert that India is in the lead in most of the S&T fields while 28% assert none of the fields and 10% express nil opinion. When asked to name some such fields in which India is in the lead, the following in the order, have emerged.

1. Space research
2. Agricultural technology
3. Textile technology
4. Atomic energy
5. Software development and advanced computer programming
6. Mathematical and social sciences and philosophy
7. Medicine and health care research.

Interestingly, these are the same S&T fields which have come under international pressures in the form of Missile Technology Control Regime (MTCR), Nuclear Nonproliferation Treaty (NPT), Trade Retaliations, Super and Special 301, and Intellectual Property Rights (IPR), Trade-Related Intellectual Property Rights (TRIPS), Trade-Related Investment Measures (TRIMS) in the Dunkel Draft Text (DDT) of General Agreement on Tariffs and Trade (GATT).

Despite such pressures, India cannot reverse its historical course of advancement. This can be better done by subjecting India's international relations, including trade and technology transfer, to the five principles of peaceful coexistence.

S&T impacts: Life-style changes

Life-styles are culture-specific. Culture is a function of man's economic relationship with nature on the one hand and other fellow human beings in the society on the other in the process of production, distribution and consumption of goods and services. The economic relationship, in turn, is a function of S&T knowledge, that induces changes in values, attitudes and aptitudes towards environment that surround the people. S&T also provides material base in the form of better goods and services that ultimately brings desirable changes in the life-styles. Accordingly, the public is well aware of the impact of S&T in changing the life-styles. Thus, about 44% respondents feel that the rate of change of life-styles due to S&T progress is too fast while 38% think neither fast nor slow, 10% feel too slow and 8% express nil opinion. Telecommunications and electronics, transportation, automation, food and agriculture, information technology, domestic appliances, medicine, computers and engineering sciences are some S&T systems, which, according to the respondents, cause the rate of change of life-styles too fast. In fact, S&T progress enables democratization of the knowledge base worldwide, leading to cultural cross-fertilization of thought processes that ultimately weed out the obsolete customs and traditions. Once such hurdles are broken, S&T becomes a material force bringing rapid changes in values and life-styles. Information technology plays a vital role in bringing such changes. And such changes, however slow or fast, are irreversible. Therefore, suitable educational programmes should be developed to enlighten the public to acquire positive attitudes towards life-styles.

Part II: Development issues and action plans

We have posed many currently debated development issues before the public and sought their perceptions,

and action plans that could guide our country's S&T programmes towards emerging world trends. The consensus outcome, as presented below, is more precise and objective, hence worthy of consideration before undertaking S&T-oriented large-scale investment ventures.

Intellectual Property Rights

Intellectual Property Rights (IPR) in the form of patents, trademarks and copyrights are granted by the country's constitutional due process as a legal instrument to promote public good, while at the same time, protecting the legitimate interests of the first inventor. Any invention which is novel and possesses economic applications is considered for grant of patent rights. But products derived from chemical, biological, biochemical and microbial reactions shall not fall under the categories of inventions or innovations as their outcomes are inherent to the processes or methods. Likewise, life forms are the products of biological evolutions independent of man's efforts. Therefore, what is inventive or innovative here are the particular processes or methods developed by men and hence worthy of granting patent rights. On the other hand, a strong IPR regime, granting patents indiscriminately and kept in force beyond the economic utility of the inventions, becomes an instrument of obstructions in the hands of monopolies, which restrict the advancement of productive forces by competitive spirits[5]. Therefore, a desirable IPR regime is one which is liberal and sensible, and promotes productivity by competitiveness and respects self-reliance of nation states. Indian Patent Act 1970 is one such, primarily aimed at promoting technological innovations, transfer and commercial production in the country. And thus it was applauded as a model patent law by all the developing countries. Even this was the case with the patent laws of the developed countries in their early stages of development. But, in recent times, India has been subjected to international pressures, trade sanctions and retaliations such as Super and Special 301, TRIPS, TRIMS of DDT of GATT, to alter its Patent Laws fundamentally to fall in the line with the strong patent regimes. This international pressure is brought under the belief that a strong patent regime indeed will help promote global trade and commerce. The Parliamentary Standing Committee on Commerce, in its 3rd Report on Dunkel Draft proposals, presented in December 1993, urged the government not to succumb but to move with caution.

In this context, about 86% of the respondents did not accept the demand for strong IPR (Patent) regime, nor did they want India to sign DDT unless GATT agrees to revise its text to accommodate the legitimate economic interests of developing countries, including India. Only 14% of the respondents favoured the demand for strong IPR (Patent) regime and signing the DDT as it is presented today. A similar trend can be seen in the write-ups of as many as 20 lead authors that appeared in the April special issue of *JSIR*[6] that devoted itself to IPR and development perspectives. Here about 65% of the authors favour defending the Indian Patent Act 1970 and country-specific liberal patent regimes, while 35% of the authors favour changing the Indian Patent Act 1970 to align with the strong patent regimes of Paris convention and DDT. Still there is a need for enlightening the public about the science of patent laws, their inherent limitations to protect the monopoly market rights of the first inventors, as in the modern S&T world; parallel discoveries, inventions and innovations can take place autonomously by the surging competitive productive forces. Under these conditions, India has to conduct its foreign relations, including trade and technology transfer, subject to the five principles of peaceful coexistence, while at the same time, safeguarding the basic features of the Indian Patent Act 1970. Now India has been a signatory to DDT of GATT (WTO). And people should learn to get along with it while safeguarding national interests as well. And the Parliament is divided on the Bill to amend the Indian Patent Act 1970, the majority not favouring.

Nuclear Nonproliferation Treaty and Global Security Plan

Nuclear Nonproliferation Treaty and Global Security Plan are the schemes operated by the clubs of 'nuclear-haves', mostly the West, to control the spread of nuclear weapon systems among the 'nuclear-havenots'. This does not discriminate between nuclear programme for peace and energy and for warfare. And there is an international pressure on India to join this exclusive club of NPT. Or else it will have to face sanctions and retaliations on imports and exports in strategic areas of nuclear energy research. Despite this, the 25 years of NPT has led to manifold proliferation of the weapon[7]. By the end of this century, there will be 20 more nations in addition to 26 with full capacity to develop their own nuclear weapons[8].

In this context, 76% of the respondents did not want India to accept NPT membership while 24% favoured it. Further, they made certain startling but relevant assertions indicating their perceptions and attitudes. Thus, NPT is not a treaty reached among equals but an imposed one. GSP is irrelevant as there is no external threat to this world. This means that the threat to this world security is from within. NPT and GSP can be accepted if there is a universal agreement to dismantle the nuclear warheads of all the countries simultaneously. Even if India joins NPT and GSP, it should not be

under duress. Similar views were expressed by a group of eminent persons in the first quarter of 1993 commissioned by the Government of India (GOI) to look into this aspect. Even a high-level study group, commissioned by the Carnegie Endowment for International Peace, in its report entitled 'India and America after cold war' suggests US not to force India to sign NPT and MTCR under duress. And the majority of the respondents think that India should reduce its budget on the Department of Atomic Energy by making nuclear power generation a commercially viable and self-supporting venture. One can reduce the burden of defence by improving friendly relationship with neighbouring countries through improved diplomacy. This demand is nothing but a call for the renewal of India's one-time cherished foreign policy based on the five principles of peaceful coexistence and nonalignment, the *Panch Sheel*: Mutual respect for each other's territorial integrity and sovereignty; mutual nonaggression; mutual noninterference in each other's internal affairs; equality and mutual benefit; and peaceful coexistence.

Earth summit and biodiversity

Concern to save the earth, protect the environment, ecology and human habitat and preserve biodiversity (in fact, it should be rightly called as *biovariety*) has attained international dimensions in the recent times. The developed countries were the forefathers, who created those systems that caused environmental pollution and ecological imbalances. But that was the way the industrialization took place under the capitalist system. The same countries, after 200 years of capitalist industrial development, exploiting world resources at their will have now attained a higher level of human development index (HDI). As S&T progresses, people's concern for a clean environment increases. The developed countries could now come with third- or fourth-generation technologies, mostly automated, which are more environment-friendly. So, the sealing was fixed on the upper limit to environmental pollution to 1992 level, which the developed countries would like to impose on the developing ones. If the developing countries, with scarce resources, technologies and skills, want to reach the same level of development of developed ones via the routes of capitalist industrialization, they have to invariably depend on the inefficient, obsolete and environment-unfriendly technologies. Such obsolete technologies, now facing a threat of closure in the West, can be easily shifted to the developing countries. Therefore, one group in the West is eager to shift such obsolete units to willing partners in the developing countries. At the same time there is another group in the West which wants to put restrictions on the development as well under some pretext with which some other groups in the developing countries would like to align either due to necessity or due to ignorance.

Likewise, the developed countries would like to consider the biodiversity (biovariety) of the world (mostly from developing countries) as universal properties and hence the demand for free access. At the same time, any improvement they make on them through S&T inputs they would like to treat as private properties, protected by IPR regimes, which the developing countries will have to acquire by paying a high price.

These are the contradictions of development inherent in the collective nature of production of knowledge and materials and the private nature of appropriation of the surpluses thus generated. The UNO (United Nations Organization) wished to reconcile the conflicts among these contradictions and strike a balance under the existing diverse sociopolitical–economic systems. This drama was enacted on the stage of the Earth Summit in June 1992 at Rio. In this context, an overwhelming majority (84% of the respondents) did agree that the Earth Summit and Biodiversity Convention 1992 were good beginnings while 16% did not consider so. However, it is observed here that the Rio Treaty and Biodiversity Convention were heavily biased towards Multinational Corporations (MNCs), which according to the majority of respondents should be checked. According to the respondents, country-specific action plans to protect national interests should be incorporated into the Treaty. Mass awareness campaigns and peace movements should be taken up vigorously to restore the lost varieties of life forms in the high tides of green revolution. India should formulate suitable policies to protect biodiversity on cooperative basis and strengthen environmental protection policies and Acts while venturing into large-scale industrial developments.

S&T in the strategic areas: Missile Technology Control Regimes

Like NPT, Missile Technology Control Regime (MTCR) is the club of advanced countries who have stock-piled heaps of missile systems. Members of MTCR are presumed to have freedom of access to high-techs in the strategic areas. But they are barred from entering into business contracts with non-MTCR member countries, mostly the developing ones, to pass on the missile technologies. Thus, by restricting missile proliferation, MTCR member countries believe that they could safeguard the global security.

As Indian space research ventured to launch Polar Satellite Launch Vehicles (PSLV), Geostationary Satellite Launch Vehicles (GSLV) programmes with cryogenic rocket engine systems, obtained from Russia on economy terms, the US has imposed a ban, under MTCR, on ISRO, restricting its deals with US companies in strategic

and aerospace industries under the pretext that Indian space programme is aimed at developing missile technologies. However, if India joins MTCR and accepts to pay higher prices, the US itself is willing to pass on the cryogenic rocket engine systems to Indian space programmes. This, according to the Chief of Glavkosmos, is nothing but a trade war[9].

In the context of trade-related conflicting interest, as cited above, over 86% of the respondents did not favour India accepting MTCR terms. They assert so for the reasons that MTCR is an imposed one and that it does not help those who want to acquire high-tech systems. The ways suggested by the respondents are to strengthen peace movements that prevail over the arms race. Further, according to the respondents, India should use its missile technology development programmes to strengthen high-tech areas in the country and then extend its cooperation among the Third-World countries.

S&T-oriented large-scale investment projects and the priorities

Today, India is torn between antagonistic group interests. Different groups think that they are exclusive to one another in the development process. Ignoring the fact that the human development is an integral part of ecological balance, the multiple dimensions of social development are counterposed to one another, instead of enabling them to play complementary roles. Thus, we see, in India, that agriculture is counterposed to industries and large-scale industries are counterposed to small-scale industries, foreign trade is counterposed to domestic trade, domestic R&D and technologies are counterposed to import of foreign technologies, large-scale S&T-oriented investment projects in irrigation, power, space, defence, communication, transport, industry and infrastructure are counterposed to environment, ecology and human habitat, population itself is counterposed to development process and so on and so forth. Even modern S&T is counterposed to the future of human civilization. Thus, we see a stagnation (or rightly stafglation) in the development.

Such conflicts emerge out of the objective realities that India continues to live with the backward and obsolete productive forces sustained by backward and obsolete production relations which were the legacies of feudal and colonial rules. However, there is a surge of technologically driven productive forces advancing in the world simultaneously raising the living standards of the people by changing their production relations on more or less democratic norms. Indian society, as an integral part of the world, is also influenced by this trend, hence the urge for advancing the productive forces. But the groups desiring to advance the productive forces through noncontractual vested interests ignore the simultaneous need for restructuring a more balanced and harmonious production relation. This is the source of conflict that counterposes several dimensions of human development, resulting in stafglation. Public perception, in this study, is more objective and balanced one. They understand the development needs of the state and the country by advancing productive forces while at the same time they appreciate the demand for restructuring production relations so as to avoid the conflicts of counterposing nature. Thus, over 74% of the respondents desire to give top priority to S&T-oriented large-scale investment projects as they give opportunities to raise the living standards of the people. Yet they assert that such large-scale investment projects often induce negative impacts on environment, ecology and human habitats. The basic principles to be respected here are the laws of conservation of biomass and bioenergy that enhance the net worth of all the groups concerned in the development process. In the absence of such corrective measures, the public prefers a large number of small projects. They assign top priority to the projects aimed at eradication of poverty, unemployment and illiteracy. They urge for reduction of import dependence in defence sectors as such a dependence does not guarantee national security. Further, they urge that defence sectors should be made to serve civil needs as well. The respondents assert that satellite communication systems, hydroelectric power projects and nonconventional energy systems should be given higher priority. The public urges not to convert natural forests into biological parks. According to them, priority to nuclear power plants can be given if the safety is guaranteed and power generation is made to earn its own return on investment. Further, they suggest to accord priority to missile technology programmes only as a means to advance high-techs in the strategic fields and earn return on investment by trading in defence systems and hardwares.

Agriculture, industry, food, health care and family welfare programmes and the priorities

Agriculture and industry depend on each other for continued growth. Agriculture being the base, industry must play a complementary role as a superstructure. India, being an agricultural country, should not ignore this fact. The public perception to this that agriculture, purely on commercial grounds, is going to endanger the food security hence needs to be checked. Educated unemployed should be urged to take up vocations in agriculture and industry. All wastelands should be brought under agriculture and awareness should be created to cultivate every piece of land. Development of agriculture and industry should promote employment and economy. And S&T should play an active role in promoting agriculture, industry, employment and

economy. Mechanization of agriculture and automation of industry should enhance labour productivity and not replace the labour force.

Food security to the people is the national security. A threat to food security to the people is a threat to national security as well. Likewise, health is wealth. Unhealthy people means unhealthy nation, and hence insecure nation. Family welfare programmes should not only aim at regulating population growth in accordance with the means to feed but should also ensure food and health to one and all. There is a unity of consensus of all the respondents that top priority should be given to these programmes. The public asserts that more investment should be allocated to such areas. And S&T should focus more to meet the need for 225–250 million tonnes of food grains for 1044 million people in 2001 AD by raising the yield per hectare manifold from the present level of: rice 1.75 tonnes, wheat 2.27 tonnes, jawar 0.82 tonnes, maize 1.52 tonnes, ragi 1.1 tonnes, potato 16.22 tonnes and sugar 5.55 tonnes[10]. It is here that the productivity of foodgrains in the country, i.e. the output per work force, should be enhanced manifold by maximizing the product of two factor ratios, viz. output per hectare of land and hectare of land per work force. Maximization of the output per hectare demands for higher orders of productive technologies and maximization of hectare of land per work force demands for implementation of Land Reform Act as well as sharing of scarce resources by cooperative spirits. Simultaneously, population explosion should be controlled by persuation and education following the Kerala model. Decentralized administration and acceleration of green revolution are suggested. Stringent checks on adulteration of food and drinks are sought. Indigenous health care systems to be strengthened on the lines of modern health care systems. One should avoid mixing up of the politics of religion, castes and communal divides with the politics of development.

Education and employment

Education and employment are the two sides of the same coin. Education is useless if it does not lead one to gainful and productive employment. Most of the country's antagonistic contradictions could be resolved if compulsory and universal education and employment are ensured to all eligible and able-bodied people. Compulsory and universal education and employment to all meet the twin objectives of people's entitlement to the wealth of knowledge and the wealth of materials on more democratic and socialized basis. In this sense, Kerala has achieved a near cent percent success in universal education. And it has yet to go a long way in ensuring compulsory and universal employment to all. Whereas India, as a whole, is many years behind in achieving both these objectives. As per the 1991 census, the literacy rate was 52.2% with a wide gap between males (43.88%) and females (39.42%). During the 1981–91 decade, the growth rate for literacy was 8.55% and that for illiteracy was 7.31%, leaving 302 million illiterates even in 1991. And about 63% of the population in the age group of 14–60 years is considered as nonworking though the unemployed registered with the employment exchanges was as high as 36.3 million in 1991, which grows at the rate of 10% per annum[11].

The public perception, in this study, desires to give encouragement to community level action plans and vocationalization of plus-two stage for attaining education and employment to all. The purpose of education should be to build a vibrant, productive self-confident, self-reliant, scientific-tempered, value-oriented, more humane and cultured society. S&T should help to create such a society.

Housing and human habitat

Housing and human habitat, in harmony with environment and ecology, is the index of developed and cultured civilizations. According to 1991 census, the demand for housing in Kerala was 11 lakh units[12]. Of these, 55% were substandard huts declared unfit for human dwelling, 27% were old ones awaiting demolition and reconstruction; only 1% were considered as standard units fit for human dwelling and 17% were considered as numerical shortage. A similar trend exists on all-India basis as well. Thus, housing the millions is a massive public task. If such a massive task is taken in a coordinated manner, it could provide immense opportunities for investment, employment, innovative and productive techniques, methods and materials. The criterion on the choice of technique is the one that delivers maximum number of housing units per given unit of resources.

The public perception here is more positive. Accordingly, S&T should focus on cost-effective, modular-type, functional and economy houses by adopting Baker's type of techniques which encourage utilization of local resources and skills that conserve materials, reduce costs and improve aesthetic values in harmony with environment and ecology. Housing design and construction should be fully engineered based on architectural principles rather than on false prestiges. Minimization of noncontractual vested interests will also reduce the costs while improving cost-effectiveness.

National defence

Agriculture, industry, S&T and defence are considered as four vital elements of any nation. Without strengthening these four aspects concurrently, one cannot think

of a modern state. They are complementary to each other and not counterposing. If improperly handled and imbalances are created, they do become counterposing to one another. Though the public perception (about 85% of the respondents) is in favour of strengthening national defence, their attitude is conditioned by the imbalances that occurred due to the stifled nature of development as seen in agriculture, industry, S&T and defence. Thus, there is a demand for cut-down in defence expenditure, unless otherwise the nation wants to do business in the military hardware. Expenditure in defence can be brought down by strengthening peace movements, imparting military training to the civilians to develop para-defence systems and improving country's diplomacy and foreign relations.

Impact of extreme events on coastal zones and small islands in the context of climate change

S. M. Kulshrestha

The paper presents a review of the current state of knowledge on the likely impacts of extreme weather and climate events on coastal zones and small islands in the context of climate change. Possible response options, including prevention, preparedness and adaptation, are indicated.

AT first glance, there appears to be little in common between the gradual onset and complex impacts of climate change and the unheralded onset and direct impacts of extreme events. While the magnitudes of the anticipated global warming and consequent sea level rise may be somewhat less than those indicated in the First Assessment Report[1] of the Intergovernmental Panel on Climate Change (IPCC), it is the extreme events and/or climate surprises that need to be taken seriously. It appears that more emphasis has to be placed on changes in frequency and/or intensity of various extreme or threshold events, particularly the extremes of temperature and precipitation, and the hazardous coastal events such as cyclones and storm surges. Such events would dominate the effects in coastal zones. The small islands would, however, appear to be highly vulnerable to accelerated sea level rise as well.

Definitions

Coastal zone: Coastal zone includes both the area of land subject to marine influence and the area of sea subject to land influence. Coastal zones are very valuable parts of the economies – both the affluent and subsistence economies. Coastal habitats provide important areas for fish and wildlife, including many endangered species. Coastal zones filter and process agricultural and industrial wastes and provide a buffer for the inland areas against cyclone and wave damages.

Small islands: Islands less than 200 km^2 in area are defined as small islands and those with area less than 20 km^2 may be called very small islands. This categorization is not entirely arbitrary and is significant in the sense that while the larger islands generally have geological features and problems similar to those found in continental regions, the small and very small islands have their own characteristics and rather unique problems. The major conglomerates of small islands are in the Pacific, the Atlantic (Caribbean), the Indian Ocean, and the territories of Indonesia and the Philippines.

Physical changes

Tegart *et al.*[2,3] have documented the potential impacts

S. M. Kulshreshta resides at B-10/7233, Vasant Kunj, New Delhi 110 070, India.

of climate change based on the studies conducted for preparing the 1990 Assessment[1] and the 1992 Supplement[2] Reports for IPCC. Among the likely physical changes in coastal zones and small islands as a result of possible climate change, the potential for, and magnitude of, accelerated sea level rise (ASLR) appears to be the greatest, especially for small islands. The projected ASLR (of the order of half a metre by the year 2100) would result in (i) substantial land inundation with especially significant impacts on coral atolls, (ii) considerable loss in agricultural activity in low-lying areas of coastal zones and small islands, (iii) coastal inundation and erosion resulting in degradation and loss of natural protective features such as dunes and mangroves apart from property damages, (iv) increased backwater effects reducing drainage from coastal streams, and (v) severe damage to surface and ground water sources due to increased intrusions of salinity. Nevertheless, as mentioned above, the major changes would be due to extreme events and climate surprises, which would also result in sudden rise of sea level apart from the other physical changes.

Accelerated sea level rise (ASLR)

Estimates of the combined effects of oceanic thermal expansion and land ice changes that could be induced by global warming involve considerable uncertainty[5]. These uncertainties are: (i) the rates of greenhouse gases (GHGs) emissions and the related changes in atmospheric concentrations and radiative forcings, (ii) feedbacks in the climate system as they affect the climate sensitivity to a given change in radiative forcing, (iii) transfer of heat from the surface to deeper waters in the oceans, (iv) regional and seasonal changes in climate, (v) model uncertainties in the computed response of ice sheets and glaciers to climate changes, and (vi) changes in ocean circulations for which adequate models are yet to be validated. Among these, thermal expansion appears to be the most significant long-term change[6]. It needs to be recognized at this stage that the ongoing research may, in the near future, result in new projections for the magnitude and the consequent physical changes due to ASLR resulting from climate change.

Enhanced extreme events – cyclones, storm surges, and heavy rains

The IPCC 1992 Supplement[4] cautioned that confidence in regional climate change patterns based directly on global climate model (GCM) output was low and that there was no consistent evidence of change in the variability of storminess. The position remains the same at present. In order to tackle this uncertainty, the models have to refine the horizontal resolution apart from other improvements.

Evans[7] made a comprehensive study of the envisaged impacts of enhanced greenhouse warming on tropical cyclones with special reference to the Australian region and concluded that in the overall, according to the present GCM simulations, preferred cyclogenesis locations remain unchanged but the potential maximum intensity could increase with the caveat that the environmental effects are ultimately the limiting factors on actual cyclone intensity and that motion will remain largely unchanged. Later work, for example, by Raper[8] indicates that there is no convincing evidence to support a relationship between sea surface temperatures (SSTs) and cyclone intensities and that an increase in SSTs may not necessarily lead to increase in the intensity of cyclones. As regards the frequency of cyclones, the link with SST appears to be through the prevailing atmospheric conditions to which both the SSTs and the tropical cyclone frequencies are closely related. Although SSTs could increase in the future due to climate change, the model predictions indicate only small changes in circulation, usually within the range of the past natural variability. There is some indication for certain areas (like the USA mainland) that the number of hurricanes striking the coast in recent years is a bit less than the average number based on the statistics of the past 100 years or so.

While evaluations of the possible impacts on coastal and estuarine surge levels due to climate change involve complex site-specific analyses, the impacts of possible ASLR on storm surge levels can be assessed on the basis that the storm surge height above the sea level plane for a given wind shear stress will be lower with higher sea level positions, where an off shore shelf is characterized by a horizontal sea bed. In the more common situations of sloping shallow offshore shelves and varying basin configurations, no direct general relationships can be deduced in terms of sea level positions and the relative differences of surge heights for given wind forces[9].

As regards heavy rain events, various lines of evidence suggest an increase under enhanced greenhouse conditions. This will probably be accompanied by an increase in deep convection and a decrease in more widespread light rain and number of rainy days in middle latitudes. These changes, coupled with increased evaporation, would result in significant reductions in the return period of floods as well as droughts[10].

Snow and ice accumulation and ice outflow

It is generally accepted that as the cause of sea level rise, the thermal expansion of oceans will dominate over the other two factors, viz. the melting of nonpolar glaciers in places like the Himalayas and New Zealand and changes in the volume of ice and snow in Antarctica

and Greenland. Practically all the GCMs suggest that an increase in precipitation over Antarctica will occur with global warming[11]. This should lead to some increase in the rate of accumulation of snow as has been observed over the recent decades in a study of ice cores[12]. The contribution of this to changes in sea level is small. Nevertheless, the complex question of snow and ice accumulation and ice outflow in Antarctica is important to the long-term question of sea level rise because the West Antarctic ice sheet, being marine-based, is potentially unstable and vulnerable to climate change. If it were to disintegrate, it would contribute about 6 m to sea level rise but such an event would occur only over many centuries[13]. Even then, this possibility is considered sufficiently significant and major research projects have been taken up[14]. Ice sheet instabilities cannot explain all aspects of the long-term climate dynamics and ocean instability needs to be taken into account but it is the ice sheet instability that seems to trigger ocean instability.

Lightning from violent thunderstorms

Lightning strikes from violent thunderstorms are very hazardous to electric power installations, aircraft, forest and the people. Even when widespread fire does not occur, lightning can cause serious damage to forests, thereby enhancing the spread of insects and diseases apart from the economic loss. According to a recent study[15], initial model results show that for a doubling of carbon dioxide scenario, global lightning activity would increase by approximately 25%. Among the climatic variables that have an impact on dangers of wildfires, relative humidity is the most important. This underlines the need for site-specific studies of the relative impacts due to increased lightning and the likely changes in relative humidity regimes locally.

Ecological impacts

The various global scenarios of sea level rise indicate an accelerating rise with no prospect of stabilization. If the seas continue to rise, coastal erosion will also accelerate and become more widespread as any compensating sedimentation declines. It will encounter, reshape, and in due course submerge the raised beaches. Because of the complexities of coastal environments and their along-shore variations, a great deal of sector-specific research is still needed to assess the extent of the geomorphological and ecological changes that will occur as the sea level rises. In assessing the nature and extent of possible changes, it is useful to classify coasts into several categories such as steep and cliffed coasts, beach fringed coasts, deltaic coasts, swampy coasts, estuaries and coastal lagoons, intertidal and near-shore areas, coral reefs and reef islands, and man-made coasts. An excellent discussion of the impacts of the rising sea level in coastal regions is given by Bird[16].

Socioeconomic impacts

In coastal zones and small islands, as indeed elsewhere as well, the socioeconomic impacts of climate change are both on the local environment and on the human societies. Those on the local environment can be analysed in terms of (a) ice and snow, (b) oceans and coasts, (c) hydrological cycle, (d) natural hazards, and (e) ecosystems and vegetation. Similarly, the possible impacts of climate change on the local human societies can be assessed in terms of (a) water resources, (b) food and agriculture, (c) coastal and island dwellers, (d) health and (e) economic activity. In actuality, the impacts occur in more complex ways and impacts in one sector affect/create further impacts in other sectors. Coastal zones and small islands are likely to suffer erosion, coastal flooding, inundation, agricultural losses, and damages to water resources and other essential infrastructure. Ironically, certain impacts could lead to a clash of interest. For example, as a result of rise in ground level temperatures due to global warming, beach seasons in coastal or island resorts would be extended bringing in more revenues – probably much more than the costs of controlling erosion and inundation that may be caused by sea level rise on account of climate change. Higher SSTs may enable new swimming areas to be developed where sea water is at present too cold to swim. On the other hand, in certain cases, adverse impacts would get accentuated such as flooding from inland waters and storm surges and rising sea level from the ocean side.

Response options – prevention, preparedness, insurance

Prevention

It is debatable if the potential impacts of climate change can be 'prevented'. Appropriate adaptation or abatement efforts are possible and should be encouraged although cost–benefit considerations will apply especially in countries with weak economies. Reduction in the emission of GHGs (including methane from garbage dumps), energy conservation, adoption of cleaner energy and manufacturing technologies, and control of atmospheric pollution (especially that from automobile exhausts) are a few of such strategies that are widely recommended.

As regards wildfires or bushfires, one technique for prevention is to light small fires (called hazard reduction burns) that consume the fuel so that during subsequent

bushfire, there is less fuel and hence less likelihood of a large uncontrollable fire[17].

Preparedness

It is possible to reduce the losses significantly if the existing knowledge and the known adjustment systems are employed[18]. These authors have listed a wide variety of available tools as follows:

Long-term
- Controlling investment, planning and development
- Management of land, resources and infrastructure
- Education and training
- Public information
- Hazard insurance
- Weather modification
- Structural engineering works
- Hazard-resistant constructions

Immediate pre-impact
- Monitoring
- Predicting
- Warning
- Shelters
- Evacuation and relocation

Impact and immediate post-impact
- Emergency management
- Hazard-fighting
- Search, rescue and salvage
- Disaster relief
- Loss compensation and rehabilitation

Insurance

The international insurance industry is already faced with a significant increase in insurance outflow due to natural disasters/extreme events during the last few decades. There are increasing demands on the insurance industry owing to the increasing population and value-added property. This is much more apparent for coastal zones, especially in affluent countries and in tourist areas, although insurance still does not command much presence in small islands except where high-value property and infrastructure are involved. The present problems faced by the insurance industry would increase if climate change results in an increase in frequency or intensity of extreme events. Meanwhile the available scenarios and projections of climate change and its impacts would tend to increase insurance premia rates, especially in coastal zones and small islands. Reinsurance would become a major and regular practice in such areas because of the magnitude of economic risk being very high and beyond the capacity of one insurer.

Adaptation options

General options

If strategies to limit the emission of GHGs are successful, the impacts on coastal zones and small islands would also be reduced. However, even if the limitation strategies succeed, there will be impacts due to climate changes already set in motion. Moreover, it is likely that initially limitation would be partial at best. Consequently there are some urgent requirements form coastal adaptation, which can be considered in the from of the following activities:

(a) Improved understanding of the climate change science and likely implications for sea level rise and other impacts such as cyclones.
(b) Monitoring of sea level and coastal change.
(c) Vulnerability studies to identify areas most likely to be prone to extreme events and sea level rise.
(d) Site-specific impact assessments.
(e) Forward planning.
(f) Public awareness.
(g) Development of a full range of coastal adaptations, including nonstructural or nonengineering options.

Specific options

In specific terms, the adaptation options for coastal zones and small islands fall into three categories, viz.

(a) Retreat: Abandon vulnerable areas and resettle.
(b) Accommodate: Adjust to the impacts, including ASLR.
(c) Protect: the vulnerable areas, especially those with large populations, high-value property and precious natural resources, and strategic installations.

An excellent discussion of the available adaptation options is given in the Report of the Coastal Zone Management Sub-Group of IPCC Working Group III[19] which also lists a very large number of references on the subject.

Social and cultural implications

People inhabiting coastal zones and small islands have distinct life-styles with characteristic social and cultural ethos. The adaptation option should not unduly strain their social and cultural values.

Sensitivities and thresholds

Definitive prediction of future climate seems impossible because a number of uncertainties are involved. Some can be reduced but others, especially those related to

future human behaviour, climate surprises and catastrophic geological or geophysical events, cannot be anticipated adequately. As future climate cannot be predicted satisfactorily (at present in any case), assessing the possible impacts of climate change requires the use of sensitivity studies over a range of possible values for relevant climatic variables. This approach enables response surfaces to be plotted showing the value of the property or the outcome considered as a function of a range of possible values of the climatic variables. Response surfaces are particularly useful because the effect of any chosen climate change scenario can be read off the graph without the need for new calculations. Examples of response surfaces are shown by Whetton *et al.*[11].

Another approach could be through calculation of quantitative indices that combine the state of climate and the economic activity into a useful number which may be regarded as an 'econoclimatic' indicator.

Conclusions

Coastal zones and small islands are very vulnerable to climate change, especially changes in extreme weather and climate events. The confidence in regional climate change patterns deduced from global climate models (GCMs) is low at present and considerable progress will have to be made before the output products of GCMs can be applied at regional or local scales. Hence, there is need for site-specific assessments of the likely impacts of climate change (especially those of extreme events)in coastal zones and small islands so that locally applicable response strategies and policy options could be developed.

New pressure-induced phase changes in CdWO4 from Raman spectroscopic and optical microscopic studies

A. Jayaraman, S. Y. Wang and S. K. Sharma

University of Hawai'i at Manoa, Hawai'i Institute of Geophysics and Planetology, Honolulu HI 96822, USA

Pressure-induced phase transitions in ABO_4 tungstates and molybdates with scheelite and wolframite structure are of interest to materials science and mineral physics. High-pressure phases with interesting physical properties can be expected. Through a high-pressure Raman and optical microscopic study we have found two novel pressure-induced phase transitions in wolframite-type $CdWO_4$. The first transition near 10 GPa is subtle, but easily observable under the polarizing microscope, as the crystal breaks into domains of colour, presumably due to a phase change accompanied by twinning, or ferroelasticity. At the second transition near 20 GPa, the Raman data clearly indicate a change in W–O coordination from basically tetrahedral to truly octahedral, a new finding of significance to high-pressure crystal chemistry.

PRESSURE-induced phase transformation in scheelite (tetragonal symmetry) ABO_4 compounds have been of current interest from the viewpoint of their high-pressure crystal chemistry[1]. Recent high-pressure Raman spectroscopic studies[2,3] have revealed that pressure-induced phase transformations are a rule in these systems. Another common structure adopted by ABO_4 tungstates at ambient pressure is the so-called wolframite type[4] and to our knowledge these have not been studied under high pressure.

Two questions of great interest in the high-pressure behaviour of ABO_4 molybdates, tungstates and rehenates are (i) whether the scheelite-type compound would transform under pressure to the wolframite-type structure and (ii) how stable is the wolframite structure itself with respect to high pressure. The best candidates to study in this connection are $CdMoO_4$ and $CdWO_4$, because the former crystallizes in the scheelite structure and sits on the border line between the scheelite–wolframite stability field[4], and $CdWO_4$ has the wolframite structure and hence is a very good candidate for clarifying the second question. Therefore, we carried out high-pressure Raman spectroscopic studies on $CdWO_4$ and $CdMoO_4$ up to 40 GPa and optical microscopic studies on $CdWO_4$ up to 20 GPa. In this article we will discuss mainly our Raman results on $CdWO_4$, and argue for a change in the coordination of tungsten to a truly octahedral coordination with respect to oxygens at the pressure-induced phase transition observed near 20 GPa. We will briefly discuss our results on $CdMoO_4$, which undergoes the anticipated scheelite to wolframite transformation as well as the phase transition involving the above-mentioned coordination change. Finally, we will present optical microscopic evidence for a subtle phase change near 10 GPa in $CdWO_4$.

High-pressure Raman experiments on $CdWO_4$ were carried out in a gasketed Mao-Bell-type diamond cell, with 4 : 1 methanol–ethanol mixture as the pressure-transmitting medium. Pressure was calibrated by the well-known ruby fluorescence technique. Raman spectra were generally recorded using a Spex Raman instrument equipped with photomultiplier. In some experiments a Spex Triplemate instrument provided with a CCD diode array detector was used to record the spectra. Figure 1 shows the Raman spectra of $CdWO_4$ obtained at three different pressures. The bottom spectrum belongs to the wolframite phase, the middle one has Raman peaks belonging to a new high-pressure phase plus the wolframite phase, and the top spectrum represents purely the high-pressure phase. Figure 2 *a* and *b* show a plot of the observed Raman peak positions as a function of pressure. Near 20 GPa the spectrum clearly changes due to a pressure-induced phase transition. Raman peaks of the wolframite phase extend beyond 20 GPa and disappear completely only above 30 GPa. Likewise, on release of pressure the high-pressure phase persists down to about 16 GPa. Below this pressure the sample is purely that of the wolframite phase. The appearance of the two-phase region shows very clearly that the transition is strongly first-order and that it is hysteretic. However, the transition is completely reversible at room temperature and the high-pressure phase is not quenchable. Now the question is what is the nature of the high-pressure phase? Only a high-pressure X-ray structure investigation can give a decisive answer, but the Raman results contain some important information regarding the structural building block, namely the coordination of the W–O polyhedra.

Detailed structural investigations on the scheelite-type ABO_4 compounds have shown that the B cation is tetrahedraly coordinated to oxygens, while the A cations

are surrounded by eight oxygens[4,5]. Raman and infrared spectra[6–8] are consistent with the presence of isolated BO_4 tetrahedra in the structure[7]. In ABO_4 of the wolframite type, such as $CdWO_4$, the B cation is regarded as sixfold-coordinated (approximately, octahedrally coordinated) with respect to oxygens, while the A cation is similarly situated with six oxygen neighbours[4]. The structure may be crudely described as hexagonally close-packed oxygens with certain octahedral sites filled with A and B cations in an ordered way[4].

The wolframite-type $CdWO_4$ has monoclinic symmetry and belongs to the space group I2/a (ref. 9). The usual view of the structural arrangement is that it consists of zigzag chains of edge-sharing WO_6 octahedra. But the description of the building blocks as octahedrally coordinated WO_6 is a highly distorted picture, for the two of the W–O distances are much larger than the four other distances to regard them as regular WO_6 units. For instance, in the isomorphous $NiWO_4$ these distances are found to be 1.79 Å for four W–O distances and 2.19 Å

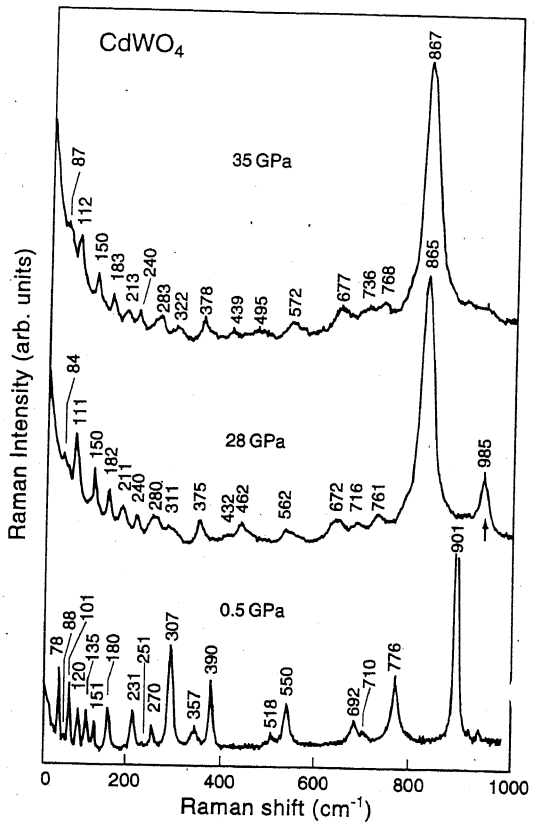

Figure 1. Raman spectra of $CdWO_4$ recorded at three different pressures with 514.5 nm line of the argon ion laser. The spectrum at 0.5 GPa is of the wolframite phase, which is the normal phase. The 28 GPa spectrum has changed and the strongest line representing the ν_1 mode frequency (865 cm^{-1}) has dropped by 120 cm^{-1} from that of the wolframite phase (985 cm^{-1}), seen to the right. The sample has not fully converted to the new phase. The wolframite peak is marked by an arrow. The spectrum at 35 GPa represents purely the new phase (see text for explanation).

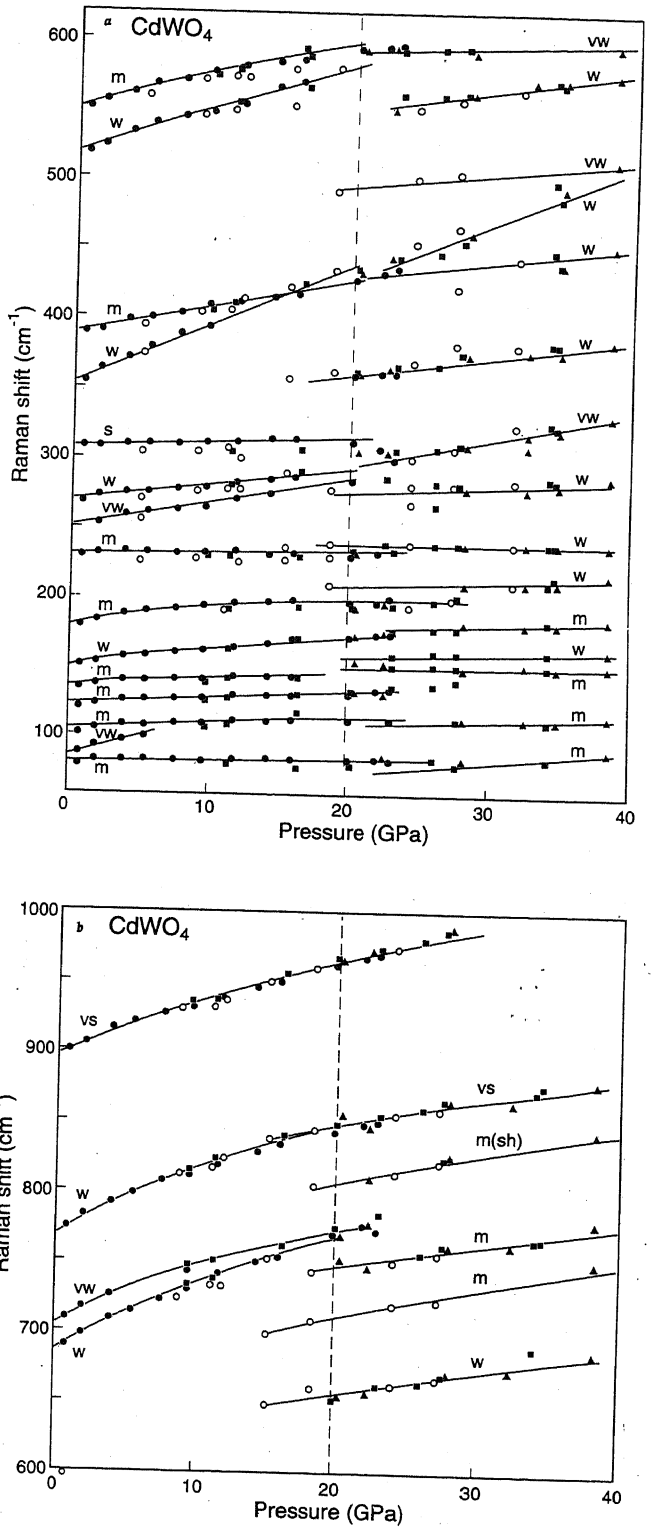

Figure 2 *a* and *b*. Pressure dependence of the observed Raman peaks in the wolframite phase as well as in the new high-pressure phase. A phase transition is marked by sudden shifts in the Raman peak frequency as well as appearance of new peaks and disappearance of old peaks. The dotted line marks the transformation pressure. The symbols s, m, w and vw appearing in the figure indicate the intensities of the Raman peaks, strong, medium, weak and very weak, respectively. Sh is shoulder. Solid lines have been drawn through the data points.

for the other two[10]. Further, it has been pointed out[7] that the Raman frequencies of WO_4 in wolframite-type $CdWO_4$ are consistent if the W–O coordination is regarded as tetrahedral rather than octahedral.

The remarkable feature in the Raman spectrum of the high-pressure phase is that the ν_1 mode frequency, which represents the totally symmetric W–O stretching vibration, drops by about 120 cm^{-1} from that of the wolframite phase at the corresponding pressure (see Figure 1) and dominates the spectrum. This is precisely what would be expected if the W–O coordination becomes truly octahedral. When the coordination increases, the bond lengths increase, and the result is a drop in mode frequency. For instance, the ν_1 mode frequency of the octahedral tungstate group (WO_6) in Ba_2CaWO_6 (refs 11, 12) crystallizing in the ordered perovskite structure is about 100 cm^{-1} lower compared to that of WO_4 in tetrahedral coordination[7]. Comparing our results with the above we conclude that in the high-pressure phase of $CdWO_4$ the coordination for W becomes truly octahedral. This would require that the WO_6 octahedrons form chains in the structure sharing four corners with neighbouring octahedra, or form zigzag chains sharing two edges, to preserve the W–O ratio. The Raman spectrum has other weak peaks in the high-frequency region which must be identified with the other internal modes appropriate for WO_6 as well as with the external modes. Obviously, the crystal symmetry will decide the splittings of both the internal and external modes. Input from a high-pressure X-ray diffraction study is needed to identify the symmetry of the high-pressure phase, which will then enable one to assign the other observed peaks. But the identification of the highest wave number peak with the ν_1 mode of the WO_6 seems reasonable, and this is a valuable piece of information that we get from Raman spectroscopy, regarding the structure of the building block. Further, the change in colour of the sample after the 20 GPa transition would also be consistent with increase in coordination, for now the crystal field acting on the 5d states of W would be much larger, resulting in an enhanced 10 DQ splitting. This would lower the conduction band and reduce the optical gap, causing the observed colour change.

Our high-pressure Raman studies on $CdMoO_4$ (ref. 13) show two pressure-induced phase transitions, one near 12 GPa and another near 25 GPa. From a detailed comparison of the Raman features of the first high-pressure phase with that of wolframite-type $CdWO_4$ it is clear that the first pressure-induced phase transition in $CdMoO_4$ is from scheelite to wolframite type. In the second transition near 25 GPa the behaviour is very similar to that observed in $CdWO_4$. The ν_1 mode drops by about 120 cm^{-1} and the spectrum is similar to that of the high-pressure phase of $CdWO_4$. This indicates that the wolframite phase transforms to a structure in which the Mo–O coordination becomes octahedral. Thus, the results of $CdMoO_4$ and $CdWO_4$ are consistent.

We have made optical observations under a microscope on thick (~ 50 μm) as well as thin (~ 20 μm) samples of $CdWO_4$ in polarized and unpolarized white light. Remarkably, a pressure-induced phase transition that is not evident in the Raman results could easily be observed near 10 GPa. The sample is normally colourless in unpolarized white light and has a uniform colour in crossed polarization. The onset of the phase transition is marked by the sudden appearance of light grey bands inside the crystal when viewed in unpolarized light. In crossed polarization the effect is spectacular, for the sample transforms into parallel domains of different colours with sharp boundaries. These are illustrated in Figure 3 *a–c*.

In crossed polarization thin samples show the colour domain vividly. With increasing pressure numerous grey-coloured parallel bands develop in the sample when viewed in unpolarized light, which in crossed polarization has a colour pattern corresponding to the bands in Figure 3 *c*. At the 20 GPa transition the pattern breaks up and is replaced by dark spaghetti-like regions, the sample acquiring a yellow colour. The yellow progressively changes to a deep orange colour with increasing pressure. Figure 3 *d* illustrates the appearance of a thicker sample near 40 GPa as seen by transmission under white light illumination.

When pressure is released, the sample does not recover its original appearance, once it breaks up into domains. The grey bands are still seen and the originally observed uniform colour over the sample area in crossed polarization is not restored. After the 20 GPa transition a reversal to a single crystal is not expected and this is borne out from our observations.

The optical observations are strong evidence for a pressure-induced phase transition near 10 GPa. In fact, when the Raman data are examined critically, a few minor changes are seen, viz. small changes of slope in the pressure vs. Raman shift plot and a small (4 wave numbers) abrupt downward shift of the strong Raman peak near 304 cm^{-1}. Now the interesting question is: What is this subtle transition in the wolframite phase? A strong possibility is that the wolframite lattice I2/a takes on the C2/c symmetry of $HgWO_4$. This would involve only a reorientation of the doubled unit cell of wolframite by a rotation around the *b*-axis, as shown by Jeitschko and Sleight[5] for the reverse case, namely the relationship between wolframite structure and the structure of $HgMoO_4$. In this transition the new unit cell volume would be the same, but the angle β is expected to be much larger than for wolframite $CdWO_4$, ~ 115° vs. 91.5°. Jeitschko and Sleight[5] describe the differences between the two structures as follows. In both the structures the oxygens form close-packed layers

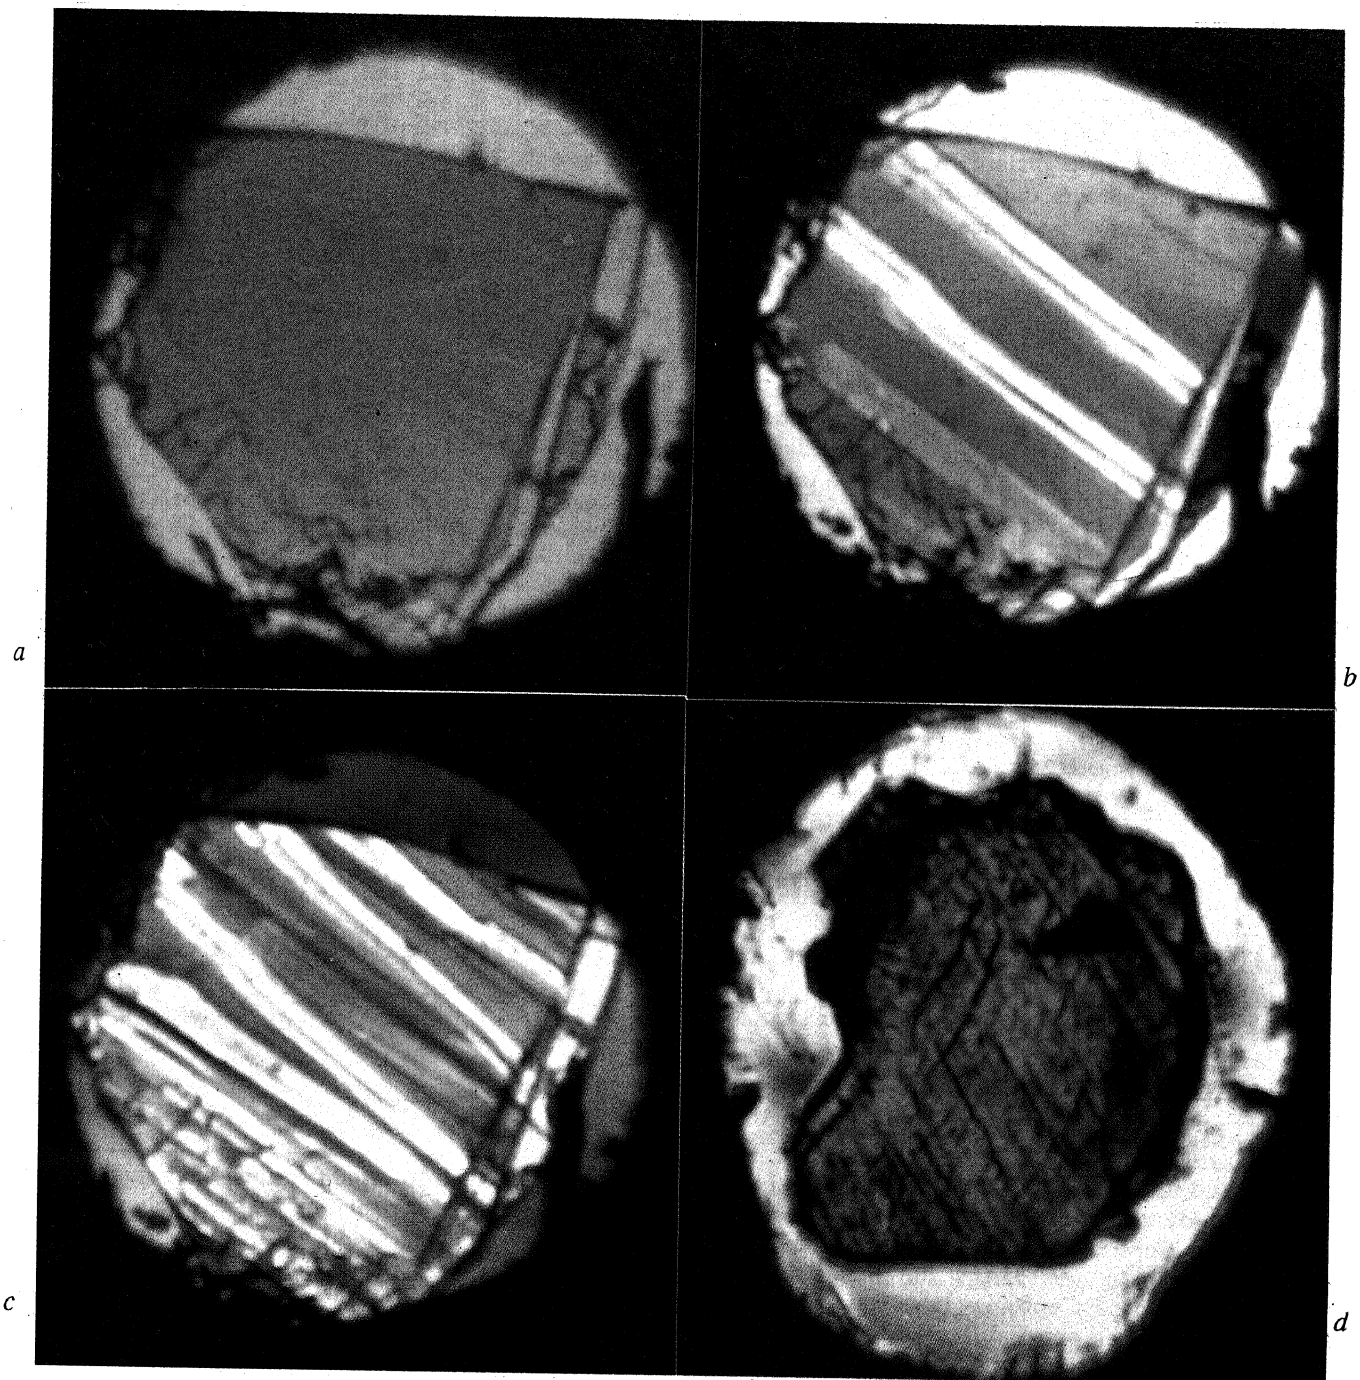

Figure 3. Photomicrographs (magnification × 400) of two $CdWO_4$ samples in the form a thin plate: *a*, *b*, *c*, taken with white light in crossed polarization at about 0.5 GPa, 9.7 GPa and 11 GPa, respectively. The uniform pink colour indicates that the sample is single crystal. In *b* the colour domains are due to a subtle phase transition (see text for explanation). In *c* the pressure has been increased and the result is that the domains multiply. The domains could be due to twinning or ferroelastic nature of the new phase. *d*, indicates the appearance of a thicker sample in transmission, with white light (unpolarized) as the source, at a pressure of about 38 GPa. The deep orange colour is believed to be connected with the second pressure-induced phase transition which involves a change in the W–O coordination, from basically tetrahedral to truly octahedral coordination. The latter transition occurs near 20 GPa and the colour of the sample progressively turns from yellow to deep orange. The sample is practically colourless and transparent before this phase transition.

parallel to the *b*–*c* plane. However, the stacking of these layers is almost perfectly hexagonal close-packed in the $CdWO_4$ wolframite structure, while it would be close to cubic close-packing in $HgMoO_4$, and $HgWO_4$. The wolframite-type $CdWO_4$ adopting the $HgWO_4$ structure would be consistent with the trends in high-pressure crystal chemistry, namely that the structure of the compound down the column in the Periodic Table is a likely structure for the high-pressure phase of the analogous compound just above it in the same column. Single-crystal high-pressure X-ray diffraction on $CdWO_4$ would be very rewarding in this connection and it is quite

feasible in the present case, since the transition pressure is 10 GPa, within the reach of hydrostatic pressure.

The subtle nature of the transition as reflected in the Raman results and the observed optical property changes would fit in the above picture. It is very likely that multiple twinning occurs during the transition and the domains are a direct consequence of it. Twinning would also explain the fact that the sample does not regain its original single-crystal character on release of pressure after the 10 GPa transition. The other possibility is that they are ferroelastic domains. The optical observations under a polarizing microscope demonstrate the power of this technique in revealing subtle phase transitions.

Our picture then for the high-pressure transformation sequence in $A^{2+}B^{6+}O_4$ compounds is scheelite to wolframite, or wolframite-like phase and then to a phase with truly octahedrally coordinated BO_6 units. There are other monoclinic structures closely related to wolframite for ABO_4 compound[5] and they are a possibility as intermediate high-pressure phases, before the transformation to the phase involving a change to octahedral coordination.

Analysis of a conformation-specific epitope of the alpha subunit of human chorionic gonadotropin: Study using monoclonal antibody probes

N. Venkatesh, G. Nagaraja and G. S. Murthy*

Centre for Reproductive Biology and Molecular Endocrinology, Indian Institute of Science, Bangalore 560 012, India

Monoclonal antibodies (MAbs) have been used extensively for identification of sequence-specific epitopes using either the ELISA or/and IRMA methods. However, attempts to use MAbs for identification of conformation-specific epitopes have been very few as they are considered very labile. We have investigated the stability of conformation-specific epitopes of human chorionic gonadotropin (hCG) using a quantitative solid-phase radioimmunoassay (SPRIA) technique. Several epitopes are stable to mild modification (chemical and proteolytic) conditions, and epitopes show differential stability for these modifications. Based on these observations, a monoclonal antibody (MAb 16) for an α-subunit-specific epitope of hCG has been used to monitor changes at the epitopic site (identified as epitope 16) on modification of hCG, using SPRIA with immobilized MAb 16. Modifications of amino groups, hydroxyl group of tyrosine as well as carboxyl group of Asp/Glu all bring about sufficient changes in the epitope integrity. Peptide bond hydrolysis at lysine residues damages the epitope, but not at arginine residues. Hydrolysis at tyrosine does not affect the epitope, though modification of the side-chain of tyrosine inactivates the epitope. Destruction of the epitope occurs on reduction of the disulphide bonds. Partial retention of the epitope activity is seen on modification of carboxyl or the ε-amino groups of lysine. Based on these results four to six amino acids have been identified to be at the epitopic site, and the data suggest that two peptide segments are brought together by the disulphide bond Cys10–Cys60 to form the epitope.

EPITOPES form a very important and specific immunochemical feature of a protein or a macromolecular antigen, and this feature of the antigen is used extensively in the development of specific radioimmunoassays, immunodiagnostics, vaccines etc.[1–4]. Epitopes are classified into sequence-specific (contiguous) and conformation-

*For correspondence.

specific (discontiguous, assembled, topographic) epitopes[5–10]. In fusion experiments MAbs are produced against both the sequence-specific and conformation-specific epitopes. Identification of these epitopes would reveal the immunochemical property of an antigen as well as provide useful clues to the three-dimensional structure of the antigen molecule. Current methods of analyses of sequence-specific epitopes using the synthetic peptides are popular and very widely used[11–17]. However, contradictory views exist as peptide fragments are poor substitutes for native antigen[18–25]. This may be because of the inability of the synthetic peptides to adopt the conformation similar to that of the native protein. Majority of antigenic determinants, which seem to consist of strongly conformation-dependent epitopes as revealed by X-ray crystallographic data and peptide binding studies[26–31], could not be uncovered by peptide approach. With the present state-of-the-art of peptide synthesis it is difficult to alter the conformation of peptides synthetically. Yet a generalized approach is not seriously attempted for the identification of conformation-specific epitopes, even though a need for it is felt acutely[32,33]. We have recently developed a quantitative solid-phase radioimmunoassay (SPRIA) technique using MAbs which extends the utility of low-affinity MAbs as well as MAb culture fluids to use them as quantitative probes for assessment of epitope integrity. Using this analytical method we demonstrate that in hCG several conformation-specific epitopes are differentially stable to treatments like enzyme digestion, chemical modification, etc., and utilize the MAb SPRIA to identify the amino acid residues contributing to the integrity of the α-specific epitope 16.

Materials and methods

Human chorionic gonadotropin (hCG) was immunoaffinity-purified from early pregnancy urine. SDS–polyacrylamide gel electrophoretic pattern was identical to purified CR 125 preparation, NIH. Iodogen method[34] was used to iodinate hCG to a specific activity of 50 μCi/μg. All assays were performed using MAb culture supernatants generously provided by Rajan Dighe, CRBME, IISc. The production and characteraction of the MAbs have been described previously[35]. $Na^{125}I$ (carrier-free) was purchased from Amersham, UK. All other reagents were of analytical grade.

Preparation of MAb-coated tubes

High-density polyethylene tubes were coated with an immunochemical bridge using a procedure similar to that described earlier for rabbit system[36]. These tubes were washed with RIA buffer, coated with appropriate dilution of MAb, and left at room temperature overnight. The following day the MAb solution was poured out, washed twice with RIA buffer and stored at 4°C until use.

SPRIA

MAb-coated tubes were incubated with 100 μl of ^{125}IhCG (100,000 cpm) and serially diluted standard hCG or modified hCG in a total volume of 600 μl of RIA buffer for 20 h at room temperature. On the subsequent day the contents of the tubes were discarded, washed twice with RIA buffer and counted in an LKB multigamma counter. ^{125}IhLH was used as a tracer in SPRIA for MAb 3 because of its better binding.

Chemical modifications of hCG

(a) Acetylation was done using acetic anhydride according to the established procedure[37]. Briefly, 200 μg of hCG in 60 μl of half-saturated sodium acetate was reacted with a total of 2 μl of acetic anhydride taken in saturated sodium acetate and vortexed, and the reaction allowed to occur for 10 min at 0°C. Acetic anhydride was added 4 times at intervals of 10 min for completion of the reaction. At the end the reaction mixture was diluted to 1 ml with water and stored for further reactions/assays at −20°C.

(b) Trinitrobenzene sulphonic acid (TNBS) reaction was carried out in 1% sodium bicarbonate solution at hCG concentration of 5 mg/ml and TNBS concentration of 0.15%, at 37–40°C for 2 h (ref. 38). The reaction was terminated by addition of 1 mg glycine in 50 μl water. The solution was made up to 1 ml in water and stored at −20°C.

(c) Biotinylation was carried out by the standard procedure using *N*-hydroxysuccinimidobiotin[39]. 150 μl of 4 mg/ml hCG in 1% sodium bicarbonate solution was mixed with 150 μl of a solution of *N*-hydroxysuccinimidobiotin (4 mg/ml in dimethyl formamide, DMF) overnight at room temperature. hCG with DMF was incubated as control. The reaction was terminated by adding 5 mg lysine and the solution was made up to 1 ml with water and stored at −20°C.

(d) Glutaraldehyde–diaminoethane reaction was carried out by reacting 200 μg of hCG (200 μl water) with 2 μl of glutaraldehyde taken in 100 μl water, and incubating at room temperature for 2 h. The reaction was terminated by adding 100 μl of 5% ethanolamine/diethylamine/glycine at pH 7 and diluted to 1 ml with water and stored at −20°C until use.

(e) Tyrosine modification was done using tetranitromethane (TNM) by the standard procedure[40]. 10 mg/ml hCG in 1% sodium bicarbonate (20 μl) was reacted with

5 µl of 1% TNM in absolute ethanol. The reaction was allowed to occur for 2 h at room temperature and terminated by diluting the reaction mixture to 1 ml with water containing 1 mg tyrosine in phosphate buffer, pH 7.0.

(f) Cleavage of methionine bonds was done by the standard procedure[41] using cyanogen bromide (CNBr). Suitable hCG control was also obtained by incubating hCG in 70% formic acid. After the reaction the solution was lyophilized and diluted with water and stored at −20°C.

(g) Modification of carboxyl groups was done using the procedure of Rice and Etzler[42]. Briefly, 50 µg hCG (20 µl) in phosphate buffer, pH 5.0, was mixed with 20 µl of 15% diaminoethane and reacted with 20 µl of freshly prepared 0.2 M 1-ethyl-3-(3-dimethyl-aminopropyl) carbodiimide (EDAC) in water. The reaction was terminated at the end of 3 h (room temperature) by adding 60 µl of 5% glycine, the volume was made up to 1 ml with water and stored at −20°C.

Enzymatic modification. Trypsin, chymotrypsin, carboxypeptidase A (CPase) and leucineaminopeptidase (LAPase) digestions were done by the standard procedure. All digestions were done at pH 8.0 in 0.2 M sodium bicarbonate solution at 37°C. The concentration of hCG used was 2 mg/ml while that of trypsin and chymotrypsin was 1 mg/ml each. CPase and LAPase were used at 10 µl/digestion. The digestion was terminated by diluting the mixture with RIA buffer containing 1% bovine serum, and stored frozen at −20°C until assay.

Chymotryptic digestion followed by CPase digestion. Chymotryptic digestion was done in duplicate as already described. The digestion was terminated by inactivating the enzyme with PMSF (1 mg). The tubes were lyophilized. One of the tubes was digested with 10 µl of CPAse A overnight at 37°C.

Estimation of the amino group. Amino groups in proteins were estimated[43] using glutamic acid as standard.

SDS–Polyacrylamide gel electrophoresis. SDS–PAGE was carried out using PhastGel gradient 8–25 and PhastGel SDS buffer strips from Pharmacia as per manufacturer's instructions. Samples were dissolved in buffer containing 10 mM Tris · HCl, 1 mM EDTA, 2.5% SDS with or without 5% β-mercaptoethanol, left in boiling water bath for 5 min and cooled, and a load of 500 ng/µl was applied. Silver staining was done using the standard procedure.

CNBr digestion and chymotryptic cleavage. CNBr digestion was done by the standard procedure and the hydrolysate was dried over NaOH in a vacuum desiccator. This was dissolved in phosphate buffer and digested with chymotrypsin as already described.

Circular dichroism (CD). CD spectra of hCG and its TNBS derivative were recorded between 190 and 250 nm at room temperature with 1 mm path length quartz cell, using a Jasco J-500A spectropolarimeter equipped with 501N data processor. Spectra were averaged over four accumulations. Protein concentrations were based on dry weight (0.5 mg/ml in 10 mM $NaHCO_3$) and the results reported as molar ellipticity values in units of deg cm^2/dmol.

Results

The extent of hydrolysis as assessed by quantitating the increase in amino groups in hCG (Table 1) after treatment with trypsin, chymotrypsin and subtilisin, and its effect on the integrity of several epitopes as measured by MAb SPRIA is shown in Table 2. In the case of subtilisin digest the number of peptide bonds hydrolysed is about 16 and results in 90% loss of binding activity as would be expected. The number of amino groups hydrolysed as measured by the TNBS method is as high as 11 (trypsin) and 4 (chymotrypsin) for digestion at 24°C and 12 (trypsin) and 8 (chymotrypsin) at 37°C. Thus, about 66% of the possible tryptic sites and 70% of the chymotryptic sites are cleaved at 37°C. In spite of this high percentage of peptide bond breakage, the structures of several epitopes are not affected (epitopes 3, 6, 16 and 21 for chymotryptic digestion and epitopes 3 and 21 for tryptic digestion, and epitope 3 for TNBS reaction) or only partially affected in all other cases (retention of activity to > 20%), with significant loss of activity occurring at epitopes 16, 21 and D11 for TNBS modification, demonstrating the rigidity of the conformation of these specific epitopes for certain modifications and their susceptibility to other modifications. It should be noted that the stability pattern is not the same for all MAb and each MAb shows its own characteristic pattern.

The SDS gel electrophoretic profile of the native hCG (Figure 1) shows two bands corresponding to

Table 1. Estimation of amino groups in hCG and proteolysed hCG

Enzyme used	Max. susceptible bonds	Amino groups measured	Peptide bonds hydrolysed
None	—	12	0
Trypsin	18	23*	11
		24**	12
Chymotrypsin	11	15*	4
		20**	8
Subtilisin	—	28**	16

*Digestion done at 24°C.
**Digestion done at 37°C.

Table 2. Binding activity of proteolysed/modified hCG to different MAbs as assessed by SPRIA

Enzyme used	No. of bonds hydrolysed	Activity (%) to				
		MAb3	MAb6	MAb16	MAb21	MAbD11
None	None	100	100	100	100	100
Trypsin	12	600	5	66	100	20
Chymotrypsin	8	600	90	90	25	20
hCG–TNBS	—	100	73	11	4	4
hCG–subtilisin	16	—	—	10	11	8

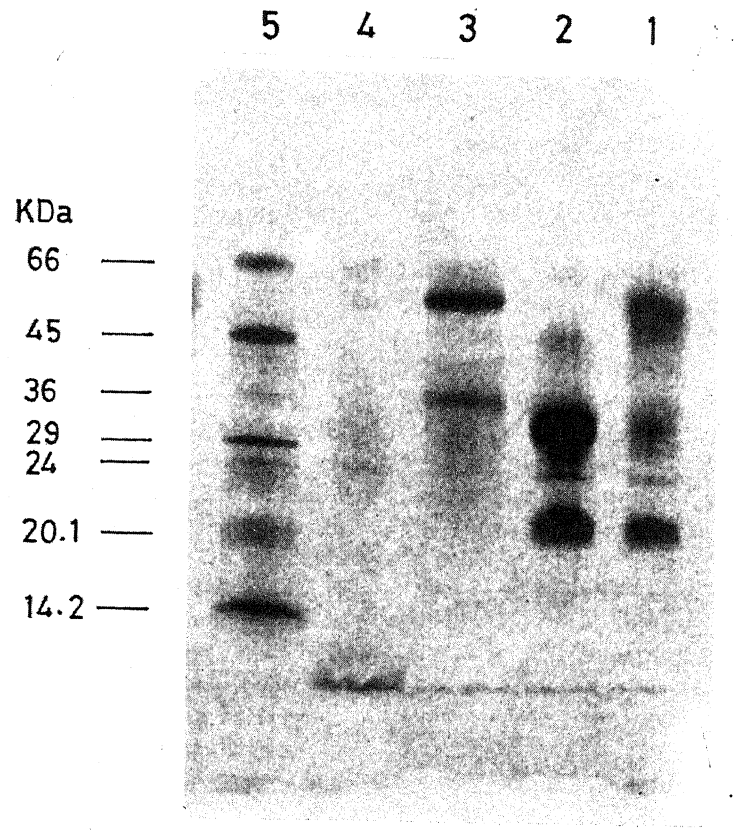

Figure 1. SDS–PAGE of hCG and its tryptic digest: lanes 1 & 2, native hCG under nonreducing and reducing conditions; lanes 3 & 4, tryptic-digested hCG under nonreducing and reducing conditions; lane 5, molecular weight markers (Sigma). Load was 500 ng in all cases and the bands were visualized by silver staining.

α and β subunits (lane 1) under reducing conditions. On digestion with trypsin these bands disappear completely, indicating that the large molecular subunits on proteolysis have been converted to small molecular peptides. In contrast, the digested hCG run under nonreducing conditions still shows large molecular subunit bands, indicating that the digested subunits are held together.

The effect of tryptic digestion (Figure 2, curve a) and acetylation (Figure 2, curve b) of hCG on its binding ability (immunoactivity) to MAb 16 shows a loss of 20% and 93% respectively. The extent of reduction of the binding activity (always refers to the ability of epitopic region to bind to MAb 16) of hCG on different chemical modifications shown in Table 3 indicates that all modifications of amino and carboxyl groups result in partial loss of activity from derivatives obtained at saturating concentration of the modifying reagent (Figure 3, where data are presented on the retention of activity with increasing concentration of TNBS used in the reaction). Complete loss of activity results only on modification of tyrosine by TNM. Neither formic acid nor peptide bond cleavage of methionine causes significant loss.

In contrast to these chemical modifications, enzymatic modifications resulted in no loss/marginal loss of activity

under normal conditions of digestion with trypsin, chymotrypsin, CPase and LAPase. However, digestion with trypsin at high concentrations (3 mg/ml) resulted in 80% loss of activity. Amino group modification of hCG with either acetylation or TNBS protected the epitope against trypsin digestion. While chymotrypsin or CPase individually did not affect the activity of the epitope, CPase digestion of the chymotryptic digest resulted in a loss of activity of about 30%. In another coupled digestion chymotryptic digestion of CNBr-treated hCG resulted in retention of activity of as much as 50%.

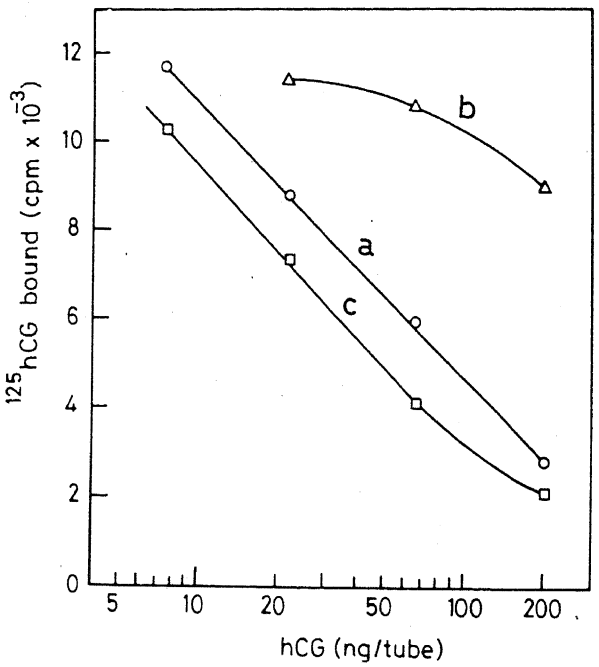

Figure 2. Displacement of ^{125}I-hCG from immobilized MAb 16 by control hCG (curve c), tryptic-digested hCG (curve a) and acetylated hCG (curve b). Tryptic digestion was done at a trypsin concentration of 1 mg/ml and hCG concentration of 2 mg/ml.

The CD spectra of hCG (Figure 4) were consistent with earlier reports[44,45] giving a negative CD band at 207 nm. The results of CD spectra of TNBS derivative indicate that no major conformational alterations have occurred due to modification with TNBS. Thus, the observed loss in epitope activity can be ascribed to the modification rather than any gross conformational change. This conclusion is further supported by the observation that all chemically modified derivatives exhibited retention of immunoactivity with one or other α-specific MAbs.

Identical results were obtained using modified derivatives of free α subunit (Table 4). As in the case of hCG, TNBS and TNM modifications resulted in loss of activity, while enzymatic modifications with trypsin and chymotrypsin resulted in partial/complete retention of activity. This observation clearly demonstrates that the presence of the β subunit is not blocking this epitope.

Discussion

Most of the studies on epitope mapping have been directed against sequence-specific epitopes, using peptide synthesis as a powerful tool in their recognition[11–17]. However, use of synthetic peptides has limitation in the studies on conformation-specific epitopes[18–25] as the conformation cannot be designed to that of native molecule by peptide synthesis. In addition, synthesizing disulphide-constrained peptides is rather difficult. Hence, attempts to use synthetic peptides have been limited, too laborious and expensive to be adopted routinely. Alternative ap-

Table 3. Effect of chemical modifications and enzymatic digestion of hCG on the binding activity to MAb16 as assessed by SPRIA

	Chemical modification			Enzyme digestion

Trypsin	K and R peptide bonds	50
Chymotrypsin	Y and F peptide bonds	100

proaches for their study have not been attempted seriously as conformation-specific epitopes have been shown to be labile and inactivated easily[46]. The use of conventional approaches used in epitope mapping, namely ELISA, IRMA, etc., suffer from the disadvantage that they are mostly semiquantitative and limit the technique to high-affinity MAbs[47,48]. With the development of a MAb-SPRIA we were able to investigate quantitatively the effect of different types of modifications which do not destroy the native disulphide bonds on different epitopic regions, like proteolysis, chemical modification, etc. The results obtained indicate that several conformation-specific epitopes on hCG are stable to a variety of treatments and show the feasibility of development of a simple approach for identifying the amino acid residues at the epitopic region.

Proteolytic digestions of hCG have been carried out at very high concentrations of enzymes to ensure maximal proteolysis. Nonspecific proteolysis using subtilisin (Table 1) causes the hydrolysis of sufficient number of peptide bonds and results in more than 90% loss of structure in all epitopes investigated, as would be expected. Considering that the best of peptides to sequence-specific epitopes exhibit only about 1% cross-reactivity compared to their native structure in the protein, retention of activity up to a level of 20–100% after 4 h hydrolysis at 37°C with specific proteases like trypsin and chymotrypsin indicates the stability of several epitopes to proteolysis at Lys/Arg and Try/Phe residues. As seen from Table 2, four of the five epitopes used here are stable to either tryptic or chymotryptic proteolysis. It is certain that hydrolysis under these conditions has occurred by SDS gel electrophoretic pattern of the digest, where reduction of the disulphide bonds results in complete disappearance of the large molecular weight fragments, and amino group estimations of hydrolysed hCG (Table 1) using TNBS. In both the digests 65–80% of the susceptible bonds are hydrolysed. Yet, the loss of activity as seen by SPRIA is insignificant in most cases, and where marginal loss of activity is seen (like MAb D11 and 6 for chymotryptic digest), the retention of the activity is far superior compared to the best achieved with an identified peptide in sequence-specific epitopes.

The unusual stability of the epitope can possibly be attributed to the disulphide bonds. Each one of the epitopes loses more than 99% activity on reduction and

carboxymethylation. X-ray crystallographic structure of hCG published recently, also indicates that the disulphides are very closely clustered, conferring rigidity to the peptide chains in proximity[49].

The number of peptide bonds cleaved by trypsin under the conditions of hydrolysis is at least 12 of the possible 18, and yet the digest remains associated (Figure 1). This indicates the rigidity of heterodimer association, probably due to the extensive disulphide network. Based on these data, enzymatic hydrolysis of hCG results in only a superficial damage to the three-dimensional structure of the molecule as a whole. It would be interesting to know whether this observation is true for other proteins which do not have such an extensive disulphide bond reinforcement.

These results demonstrate the feasibility of proteolysis in conjunction with assessment of MAb activity as a powerful tool in identifying the amino acid residues contributing for the epitope conformation. TNBS modification of the amino groups of lysine residues results in a loss of about 90% activity (Table 2) in epitopes 6, 16 and 21, while the integrity of epitopes 3 and 6 seems to be unaltered. The gross structural integrity of the chemically modified hCG is evident from the CD spectra (Figure 4) and this attributes the losses of activity seen for epitopes 16, 21 and D11 to the presence/proximity of the ε amino groups of lysine residues in these epitopes. In contrast, the epitope regions 3 and 6 are not significantly altered by TNBS reaction, ruling out the proximity of the ε-amino group of lysines near these epitopes. Retention of epitope activity by TNBS modification of hCG in epitopes 3 and 6 clearly demonstrates that these epitopes do not have a side-chain residue of lysine nearby. This observation, namely different modifications affecting epitope integrity differentially, provides us with a tool which has been used in the analysis of epitope 16, described in the following.

Chemical modification of the amino groups of lysine residues done by several methods (Table 3) demonstrates that there is a significant loss of activity. While acetylation and glutaraldehyde–DAE modification reduces the activity by 90%, other reagents namely biotinylation and TNBS, reduce the activity by >95%. The CD data of the TNBS derivative (Figure 4) clearly show that gross structural changes are not occurring on modification. Thus, the loss of the activity of the epitope on modification may be ascribed to the presence of the ε amino group of a lysine residue at or near the epitopic region. Similarly, the side-chain of tyrosine is very closely associated with this epitope, as TNM modification results in almost total loss of activity. Here again the loss of activity cannot be ascribed to gross structural changes as the CD spectra of the TNM derivative rule out such a change. The presence of a carboxyl group near the epitope is also obvious as chemical modification of carboxyl groups reduces the activity to nearly 25%. These data clearly put a lysine, a tyrosine and an acidic amino acid at the epitope region. Reduction and carboxymethylation of the disulphide bonds of hCG completely abolish the activity (>99.9%) indicating the importance of the disulphide bridge in the integrity of the epitope.

Enzymatic hydrolysis of the hCG/derivatives (Table 3) indicates an important role for the peptide bond of a lysine or an arginine residue as hydrolysis by trypsin at low concentrations eliminates the activity significantly (30%), and to a great extent at high concentrations of trypsin (90%). This observation indicates that this bond is not easily susceptible to enzyme digestion, as has been shown earlier[50]. Tryptic digestion of acetylated hCG does not result in further loss of activity, and hence rules out the importance of arginine residue in the integrity of the epitope (Table 3). Similarly, a role for the peptide bonds of Y or F is ruled out as chymotryptic hydrolysis does not cause loss of activity. Retention of full activity by both LAPase digestion and CPase A digestion puts the terminal portions of the molecule away from the epitopic site. Hydrolysis of the peptide bond adjacent to methionine residues is also not important, since the CNBr-treated hCG retains complete activity.

The results of chemical modification of the α subunit also lead to the same conclusions. Proximity of a K and a Y side-chain is clearly indicated (Table 4). Similarly, the involvement of a lysine carboxyl peptide bond is obvious. Thus, all these results establish that the presence of the β subunit has not altered the epitope region.

Modification data indicate that the epitopic region is comprised of residues of lysine, tyrosine and an acidic amino acid nearer to a disulphide bond. Primary structure of the α subunit has one sequence having all the three amino acids in close proximity (Y88–S92). CPase hydrolysis does not result in loss of the epitope activity and hence rules out the contribution of these residues to the epitopic structure. However, there are other sequences C60–Y65 and C10–E9, which bring the three

amino acids to proximity through the disulphide bond C60–C10. Thus, tentatively we can identify E9–C10 and C60–K63–Y65 to be the sequences at the epitopic region.

Elimination of other Tyr and Lys residues can be done indirectly. Thus, K44 and K45 are eliminated because CNBr–hCG when treated with chymotrypsin retains almost 50% activity, a process wherein elimination of the peptide bond 33–47 is effected. K75 can be easily eliminated because of the stability of the epitope to chymotryptic digestion as well as its distance from a disulphide bridge. X-ray structure also puts this amino acid residue away from the core[49]. Lys 90 is eliminated on the basis of the stability of the epitope to CPase digestion of hCG. Lys 51, while near an acidic group is far away from a disulphide bond. These results point out to a region as probable epitope region for MAb 16 (Figure 5 *a*).

This conclusion is further substantiated by the observation that CPase digestion of chymotryptic digest causes 30% loss of activity. This is because the chymotryptic digest partially cleaves the Y65, exposing a tyrosine for CPase digestion, which causes the removal of Y65, resulting in loss of activity. Loss of activity to only 30% may indicate relative inaccessibility of Y65 to proteolysis, documented earlier[50]. Our own data (Table 1) also point to the inaccessibility of this region to proteolytic digestion.

Based on the above experimental data, we propose that the region corresponding to this epitope is as shown in Figure 5 *a*. The amino acids identified directly by chemical modification procedure are E9, C10, C60, K63 and Y65.

The data presented here convincingly show the importance of the disulphide bonds in the formation of this epitope. Hydrolysis of several peptide bonds does not alter the epitope structure, but reducing the disulphide bonds keeping each of the peptide bonds intact results in complete loss of activity and, hence, epitopic structure. This conformation-specific epitope seems to be almost a sequence-specific epitope through disulphide bridges (^{10}EC–C^{60}VAKSYN^{66}). It is notable that breaking the peptide bonds at 60–82 loop and/or 32–60 loop (by digestion with trypsin, chymotrypsin or CNBr) does not affect the integrity of this epitope. Thus, the integrity of this epitope is maintained more by disulphide bonds than by peptide bonds. The stabilizing force may not be the disulphide bond 10–60 exclusively. The rigid network of disulphide structure comprising cystine loops 7–31, 10–60, 59–87 and 84–32 (Figure 5) presents a structure (stable to proteolysis) which may be a strong force in keeping the integrity of this epitope. However, it is not possible to analyse the exact contribution of this network of the disulphide structures to the epitope stability in this case as the aminoacids 7–10 and 84–87 are not susceptible to any type of mild chemical or enzymatic cleavage, and selective reduction of these disulphide bonds has not been reported.

One of the arguments against the logic developed for analysis of epitopes by this method is that a modification at a site may induce conformational relaxation in the molecule at a distant epitope region. It is unlikely that a positive proof for or against this argument can be obtained. However, a large number of modifications like tryptic digestion (12 peptide bonds are cleaved), chymotryptic digestion (9 peptide bonds are cleaved) and TNBS modification (12 amino groups are modified) should induce sufficient long-range relaxations all over the molecule (all these modifications whether proteolysis or chemical modification are uniformly distributed, as can be seen by the sequence) and yet the effect on the epitopic activity is very specific. In addition, it is seen that modification of the amino group with different reagents like acetic anhydride, TNBS, biotin or Gld–DAE brings comparable loss of activity in spite of different side-chain groups (Table 3). These observations provide an indirect evidence that conformational relaxation at distant epitopic regions may not be the reason for the specific effects seen. This is possible considering that hCG has a very rigid, interwoven network of disulphide bridges. It would be interesting to know how the integrity of epitopes of a protein with few disulphide bridges is affected by modifications, as done above.

Currently available methods for identification of amino acid residues at conformation-specific epitopes rely on X-ray crystallographic data of Ag–Ab complex[51] or cross-species comparison using naturally occurring variants or mutant chimera[52,53]. These methods, though powerful, are adopted rather rarely as the method has no easy accessibility/adoptability to most of the

laboratories. The method we have described above has an easy adoptability to routine laboratory with RIA facility, and is inexpensive and faster for identification of amino acid residues at epitopic regions. Our own experiments done with several epitopes of hCG indicate that this method is extendable to other epitopes of hCG and has the potential to become a general method for identification of epitopic regions for proteins with extensive disulphide bonds like gonadotropins. In addition, the method will have a greater reach to most of the laboratories when the RIAs are converted to EIAs, for which attempts are in progress.

On minimum metallic diffusivity in disordered conductors

N. Kumar and A. M. Jayannavar*

Raman Research Institute, Bangalore 560 080, India
*Institute of Physics, Bhubaneswar 751 005, India

It is shown that the formal consistency of a locally diffusive motion on the metallic side of the mobility edge for a disordered system with the Schrödinger equation implies a minimum metallic diffusivity $D_{min} = \hbar/2m$. Its implification for the physics near the mobility edge is discussed.

METALLIC conductivity σ implies diffusivity D through the Einstein relation for the degenerate electron system, namely, $\sigma = e^2 D N_F$. For a quench-disordered conductor, this poses the question of formal consistency of the diffusive equation for the probability density with the Schrödinger equation for the probability amplitude. In what follows we address this question and find the surprising result that a necessary condition is $D_{min} = \hbar/2m$.

Consider a phase space wave packet initially localized around the origin and constituted from the extended energy eigenstates close to the Fermi energy (counted as zero of energy) which is taken to lie just on the metallic side of the mobility edge for the quench-disordered system.

Rewrite the Schrödinger equation for the wave packet

$$\psi(x, t) = R(x, t)\, e^{i\phi(x,t)} \equiv e^{\alpha(x,t) + i\beta(x,t)} \tag{1}$$

as

$$-\hbar \frac{\partial \phi}{\partial t} = \frac{\hbar^2}{2m} (\nabla \phi)^2 + V - \frac{\hbar^2}{2m} \frac{\nabla^2 R}{R} \tag{2}$$

along with the continuity equation

$$\frac{\partial \rho}{\partial t} + \frac{\hbar}{m} \nabla \cdot (\rho \nabla \phi) = 0 \tag{3}$$

with $\rho = \psi^* \psi$.

Now, we would like the continuity equation for the probability density to converge asymptotically to the diffusive form

$$\frac{\partial \rho}{\partial t} = D \nabla^2 \rho. \tag{4}$$

Comparing eqs. (3) and (4), we at once get a condition for this to be so in terms of α and β, which is

$$\frac{\hbar}{2m} \nabla \beta = D \nabla \alpha \tag{5}$$

assuming $\nabla\alpha$ to be irrotational.

We now substitute in eq. (2) from eq. (5) and rearrange to get

$$-\hbar \frac{\partial \beta}{\partial t} = V - \frac{\hbar^3}{4m^2 D} \nabla^2 \beta + \frac{\hbar^2}{2m} \left(1 - \left(\frac{\hbar}{2mD}\right)^2\right) (\nabla \beta)^2. \tag{6}$$

Now, averaging over the disorder V and noting that odd-symmetric quantities, i.e. $\langle \beta \rangle = \nabla^2 \langle \beta \rangle = \langle V \rangle = 0$, while $\langle (\nabla \beta)^2 \rangle \neq 0$, we necessarily have

$$D = \left(\frac{\hbar}{2m}\right). \tag{7}$$

Here, of course, we have regarded D as a self-averaging quantity. This is reasonable as we know that on the metallic side of the mobility edge in three dimensions the conductance fluctuations are universal ($\sim e^2/h$), but the conductivity fluctuation is $\sim (e^2/h)(1/L)$ and, therefore, vanishes in the infinite sample size (L) limit. We must note that our sample size L is always taken to be essentially infinite ($\gg$ any correlation length ξ that may exist as we approach the mobility edge). This ensures that we are always in the local diffusive regime in that the mean-squared displacement grows linearly in time as $2Dt$. For $L \leq \xi$, the diffusion constant itself can, of course, be L-dependent. This is, however, quite different from the anomalous diffusion, where the mean-squared displacement does *not* grow linearly with time. Further, we have insisted on the local diffusion equation (4) and this forces us physically to the limit when the mean free path equals the microscopic length – the Fermi wavelength ~ the lattice discreteness. The latter implies that we should be closest to the mobility edge, but on the metallic side. Thus, $\hbar/2m$ is to be taken as the minimum possible value of D to ensure local diffusion.

As to the general conceptual question of how diffusion of an initially localized wave packet may come out of the Schrödinger equation with quenched (static) disorder, we consider the following. Of course, in the static random potential there is no dissipation and hence no irreversibility that one normally associates with the inelastic (incoherent) scatterings. Indeed, in the strictly fine-grained sense there is no irreversible diffusive spread of the electron wave packet, and eq. (3) is time-reversal-symmetric (i.e. under $t \to -t$ and $\phi \to -\phi$). This old problem[1] is the same as that discussed recently by Imry[2] in the context of the nonzero real part of the dc conductivity. The point is that for the extended states the level spacing scales to zero as the system size tends to infinity, i.e. the poles produce a cut. Then arbitrarily small level broadening will ensure the phase-mixedupness of the otherwise pure state and thus ensure irreversibility in the long-time limit. This is really an analogue of the collisonless Landau damping! Indeed, Mott and Kaveh[3] have discussed the diffusion equation as arising from the Schrödinger equation for a disordered system.

The above derivation strongly suggests that there exists a minimum metallic diffusivity D_{min} having a universal value $\hbar/2m$ *whenever* a mobility edge is known to exist. The question now is whether or not this implies a minimum metallic conductivity[4] σ_{min} through the Einstein relation $\sigma = e^2 D N_F$. This brings us to an oft-stated but seldom proven theorem[5], namely, that the localized states cannot coexist with (be at the same energy) as the extended states. And this notwithstanding the well-known counterexamples of the Wigner–von Neumann construction of such states[6]. The latter seem to be dismissed as nongeneric. If the coexistence is denied, the N_F on the metallic side of the mobility edge counts the total density of states (there being no coexisting localized states) and then $D_{min} = \hbar/2m$ would imply a $\sigma^{3D}_{min} = e^2 D_{min} N_F$. In this connection it is worth noting that the ultrathin films of Bi on Ge substrate show[7] a limiting normal metallic conductivity of $4e^2/h$ (corresponding to a sheet resistance $\sim 6.5\ k\Omega/\square$) for the separatrix dividing the insulating and the superconducting phases at 0 K. This may well be associated with the preexisting local electron pairs where the correlated motion of the pairing electron escapes the tyranny of two-dimensional (2D) localization. Now, it is interesting that our universal $D_{min} = \hbar/2m$, along with $N_F = (m/\pi\hbar^2)$ for $d = 2$ does indeed give $\sigma^{2D}_{\square} = 4e^2/h$. We would like to call it the σ^{2D}_{min} of Mott recovered through delocalization by pairing in two dimensions. This may be the case for all insulator–superconductor transitions with a normal-state separatrix for the ultrathin films.

There is, however, the question of the fine structure of the mobility edge for $d = 3$, where the conductivity is experimentally believed to vanish continuously[8] at the mobility edge in a narrow critical region with a critical exponent s. How is this consistent with $D_{min} \neq 0$? A possible solution consistent with $D_{min} \neq 0$ is to assume that $N_F = N_F(\text{localized}) + N_F(\text{extended})$. What then enters the Einstein relation is, of course, the $N_F(\text{extended})$, which can vanish at the mobility edge keeping the total N_F continuous and noncritical, as is known to be the case. It is not clear how this two-spectral fluid hypothesis[5], i.e. $N_F(E) = N_F(\text{localized}) + N_F(\text{extended})$, really differs from the asymptotic form of the resonance-like wave function in three dimensions adduced by Kaveh and Mott[9]. Such quasilocalized resonant states are strongly suggested by some recent works[10,11]. We think that a proper discussion on this point is yet to take place.

Finally, two technical remarks are in order. First, the validity of our eqn. (5) at any point x demands that x not be a node where $\psi(x)$ vanishes. But this condition is naturally obeyed by all diffusive states. Indeed, vanishing of $\psi(x)$ would imply vanishing of $\rho(x) = \psi^*(x)\,\psi(x)$, which is ruled out by the fact that $\rho(x)$ is requested to obey the diffusion equation (3). The second point concerns the absolute value $4e^2/h$ for the sheet conductance of films referred to in the text, i.e. for Bi films on Ge. The point is that the effective band mass does not appear in the expression, and the correction to the density of states due to disorder or interaction is cancelled by the vertex correction, at least perturbatively – the well-known cancellation theorem valid in the absence of a pseudo gap[12].

An *ab initio* topographical investigation on the molecular electrostatic potential of some chemical mutagens

Apurba K. Bhattacharjee, Savita S. Pundlik* and Shridhar R. Gadre*

Department of Chemistry, Lady Keane College, Shillong 793 001, India
*Department of Chemistry, University of Poona, Pune 411 007, India

A detailed topographical investigation on the molecular electrostatic potentials (MESPs) of different conformers of acetaldehyde, nitrous acid and hydroxylamine has been carried out at the *ab initio* SCF level using TZ2p, 6-31G* and STO-3G basis sets. In general, large regions of negative potential have been observed. An attempt has been made to correlate these potentials with biological activities of the molecules. Mutagenic and toxicological properties appear to be related to the presence of these large negative zones.

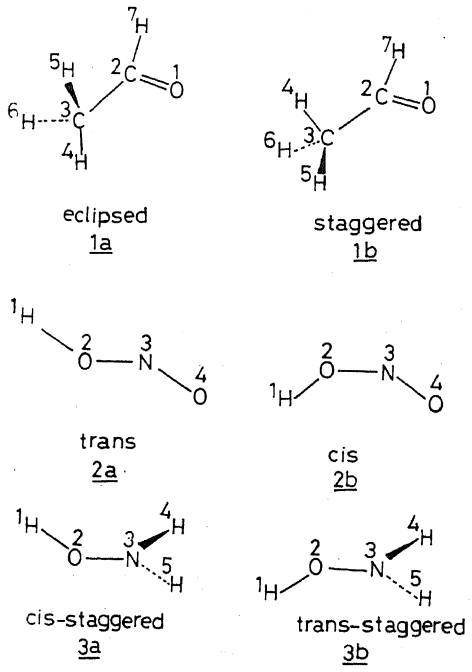
MOLECULAR electrostatic potential (MESP) is now an established tool for the study of the stereoelectronic

attributes and properties of binding molecules which would significantly contribute to the elucidation of biochemical phenomena[1–3]. Even long-range electrostatic interactions have now been shown to be important for a number of biological reactions including folding of proteins, determination of pKa's of the ionizable residues etc.[4]. The affinity of a particular molecule for a specific receptor is shown to depend on the MESP characteristics[5]. This ability of a molecule for interaction with the receptor is essentially known as the 'recognition' process, in which the receptor 'recognizes' the characteristic features of the molecule in order to promote their interaction. MESP can, therefore, be used for predicting structure–activity relationships when a receptor-mediated response is supposed to give rise to toxicological, mutagenic or carcinogenic effects even without a detailed knowledge of the receptor[6]. MESP provides the exact value for the electrostatic component of the interaction energy between an unperturbed charge distribution and a proton[7]. Moreover, MESP gives a general picture of the reactive properties of the molecule with a reasonable computational cost and this explains its large number of applications in very different fields of physics, chemistry, biochemistry and pharmacology[8]. In a recent report Zhu *et al.*[9] have shown that radiosensitizers can be made based on MESP data, thereby indicating its possible applications in the study of molecular toxicology. Efficient radiosensitizers are characterized by a wide and deep negative potential in their MESP profiles, while this potential is narrow for compounds devoid of significant activity[9].

The MESP $V(r)$ at a point r due to nuclear charges $\{Z_A\}$ at $\{R_A\}$ and the electronic density $\rho(r)$ of the molecule is given by

$$V(r) = \sum_A \frac{Z_A}{|R_A - r|} - \int \frac{\rho(r')}{|r - r'|}\, d^3r'. \qquad (1)$$

The first term on the right-hand side of this equation represents the bare nuclear potential while the second one represents the electronic density function of the molecule. The sign of $V(r)$ in any particular region depends on whether the nuclear or the electronic effects are dominant there.



The topographical analysis of $V(r)$ involves identification and location of the critical points (CPs)[10,11], the points at which $\nabla V(r) = 0$. A CP in the MESP topography specifies a point at which the internal electric field (molecular electric field or all the partial derivatives of MESP) is exactly zero. This implies that the numerical value of the molecular electric field can be used for locating CPs in the MESP topography. The rank of the CP is given by the number of nonzero eigenvalues of the Hessian matrix $\boldsymbol{A}$, whose elements are given by

$$A_{ij} = \frac{\partial^2 V}{\partial r_i\, \partial r_j}\Bigg|_{r = r_{CP}}. \qquad (2)$$

A CP of rank 3 (known as a nondegenerate CP) is characterized by the algebraic sum of the signs of eigenvalues. Thus, there are four possible types of CPs: (3, –3), (3, –1), (3, +1) and (3, +3). The (3, –3) CP cannot exist in $V(r)$ except at the nuclear locations[11]. A (3, –1) or (3, +1) CP would correspond to saddle points whereas a (3, +3) CP is due to the local minimum of $V(r)$ beyond the van der Waals surface of the molecule.

The MESP minima can give an idea of the deprotonation sites as well as the interaction possibilities at the electrophilic centres of the receptor. Since MESP reflects the molecular interaction energy with a test positive point charge, the (3, +3) CPs would correspond to their proton affinities[12]. This would imply a threshold interaction energy of the atoms in the molecule to extract a proton from the proton donor site on the receptor. Good correlations between proton affinity or hydrogen bond acceptor parameters and MESP have been established in the recent past[13].

Chemical mutagens act by modifying the bases of DNA. Nitrous acid, hydroxylamine and acetaldehyde are all well-known mutagens[14]. Nitrous acid causes AT ↔ GC transitions whereas hydroxylamine is a highly specific mutagen which reacts almost exclusively with cytosine to give a derivative that pairs with adenine rather than with guanine and so it produces a unidirectional transition of CG to AT[14]. Acetaldehyde has also been reported[15] to be highly toxic, comparable to nitrous acid and hydroxylamine. These molecules, apart from their toxicities, are also known to be efficient proton removers and deaminating agents[16]. Further, these molecules are also interesting because there is a strong evidence that they can act as mutagens most likely at the same site[12].

The objective of the present study is to assess the importance of three-dimensional MESP topographical analysis of acetaldehyde (1a, 1b), nitrous acid (2a, 2b) and hydroxylamine (3a, 3b) at a higher level of theory in the mutagen–receptor interaction process. Although electron density maps of some of these molecules[17] have been reported earlier, to our knowledge detailed topographical analysis at this level of theory has not been reported so far in the literature.

We have used *ab initio* optimized geometries of three molecules in their different conformations[17–19] and obtained the wave functions (with TZ2p, 6-31G* and STO-3G basis sets) by using the INDMOL package[20] on a 64-node transputer-based machine called PARAM[21]. The MESP calculations were carried out using these wave functions on the same computer with the help of a program developed by Shirsat *et al.*[22]. The computed electrostatic potentials are at a distance of about 3 a.u. surrounding the molecule, which corresponds approximately to the van der Waals radius of the largest atom in this group of molecules (oxygen)[23]. The potential at this surface would usually be encountered by the receptor during the 'recognition' process. The basis set dependence of the MESP was checked by using different basis sets in these calculations. The CPs were located using the analytical expressions for the gradient of $V(r)$ given by Gadre *et al.*[10,24].

In order to have a quantitative measure of the negative region typical for biological recognition interaction[3], we have calculated the volume inside a closed surface having an MESP energy of –15.6 kcal/mol. This is done by calculating MESP values on a 64-node PARAM machine[21] inside a rectangular parallelopiped enclosing an isosurface of this energy and sampling the points through a random search (Monte Carlo method). The volumes thus obtained for all the molecules studied are indicated in Table 1.

In Table 1, the CP characteristics of the molecules studied at TZ2p level are presented. The calculated MESP minima (most negative values) are beyond the van der Waals surface of the molecules. The electrostatic potential maps of the molecules are presented in Figure 1.

In acetaldehyde, practically no energy difference is found between the MESP critical points of the eclipsed and the staggered conformations, which indicates that the MESP profile is independent of methyl rotation, although methyl barrier to internal rotation around the C=O bond has been calculated at the 6-31G* level to be 1.06 kcal/mol (ref. 17). The two negative-valued minima are found in the lone pair regions of oxygen in both the rotamers. The TZ2p MESP maps of both the rotamers show the presence of strong negative potential zones laterally around oxygen encompassing a broad region which might be linked to the strong biological activity of the molecule. The negative regions

Table 1. Types and locations of negative-valued MESP critical points (CPs) calculated at TZ2p level

associated with the carbonyl oxygen extend to a fairly large region; the minima representing the lone pairs have a value around –51.0 kcal/mol separated by a saddle corresponding to about –46.0 kcal/mol.

In the case of *trans*-nitrous acid, seven distinct CPs with a deepest minimum of about –37.0 kcal/mol are observed. A large extended area of about –20.0 kcal/mol is observed which is most likely to be the characteristic feature of the 'recognition' interaction. For *cis*-nitrous acid, six CPs were located, with the deepest minimum at –30.0 kcal/mol. A broad extended area of about –8.0 kcal/mol is observed as the saddle energy.

Cis-staggered hydroxylamine shows three minima, two of which are at –68.0 and the other one is at –53.0 kcal/mol. A saddle energy range of about –40.0 to –50.0 kcal/mol is found to be extended over a large area on only one side of the molecule. In the case of *trans*-staggered hydroxylamine, however, the MESP

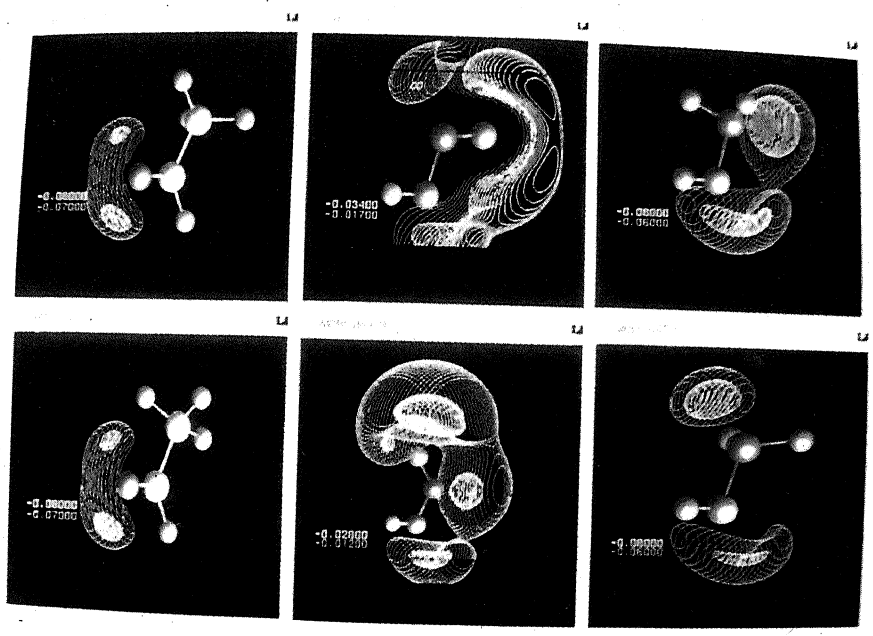

Figure 1. The molecular electrostatic potential contours of: *a*, acetaldehyde eclipsed (upper) and staggered (lower). The green colour corresponds to a value of –44.0 kcal/mol, while the pink one corresponds to –50.2 kcal/mol. *b*, *Trans*-nitrous acid (upper) showing green colour contours of –10.6 kcal/mol and pink colour contours of –21.3 kcal/mol, and *cis*-nitrous acid (lower) showing green colour contours of –7.5 kcal/mol and pink colour contours of –17.5 kcal/mol. *c*, Hydroxylamine *cis*-staggered (upper) and *trans*-staggered (lower). The green colour corresponds to a value of –37.6 kcal/mol, while the pink one corresponds to –50.2 kcal/mol.

minima are localized on both sides of the molecule, one near oxygen and the other near nitrogen, with the potential values of –50.8 and –62.7 kcal/mol, respectively. The saddle energy of about –40.0 kcal/mol is found to be well extended on both sides of this molecule.

Calculations made at the 6-31G* level could reproduce similar MESP profiles for all the molecules. For *cis*-staggered hydroxylamine, however, the two minima off the *xy* plane obtained with TZ2p basis could not be distinguished and they appeared to have converged into a single one in the plane.

Although STO-3G calculations show qualitative similarity of the MESP features of the molecules, the locations and the potential values of the CPs differ significantly. In acetaldehyde, for example, the deepest minimum has a higher value of MESP (–34.0 kcal/mol) and in *cis*-nitrous acid, it is as low as – 49.0 kcal/mol. Thus, the choice of STO-3G basis sets for MESP calculations of such molecules should perhaps be made with caution.

The magnitudes of the negative-valued minima of all the molecules may be correlated with their proton affinities. This is because MESP reflects the molecular interaction energy with a positive point charge; therefore, this MESP minimum threshold would correspond to the proton affinity of the molecules (the amount of energy necessary to extract a proton from the proton donor site on the receptor). Such correlations have been reported earlier for a series of oxygen- and nitrogen-containing molecules[12,25].

In order to compare the biological activities, we have scanned volumes enclosed within the negative region having potentials in the neighbourhood of –15.0 kcal/mol for all the molecules. A value of such a magnitude has been reported by Murray *et al.*[3] as optimum potential minimum to explain the toxicities of several dibenzo-*p*-dioxins. In our scan, we too observe (Table 1) a very large area being encompassed with this energy. It may thus be reasonable to infer that both the depth of the MESP minima and the magnitude of the 'volumes' together play a crucial role in the biological interaction process. From an inspection of the 'volume enclosure' of –15.6 kcal/mol, it is apparent that both the rotamers of acetaldehyde (eclipsed 239.8 a.u^3 and staggered 241.4 a.u^3) and *cis*-staggered hydroxylamine (278.8 a.u^3) are more prone to biological recognition interaction than *trans*-staggered hydroxylamine (123.0 a.u^3), *trans*-nitrous acid (156.0 a.u^3) and *cis*-nitrous acid (34.0 a.u^3). It may be summarized from the above results that *cis*-staggered hydroxylamine would be biologically more active, followed by the two acetaldehyde rotamers. Apart from having high negative potential regions the molecules are much smaller in size, which enable them to a greater accessibility to the receptor site. Thus, three factors – (i) the magnitude of the deepest negative potential, (ii) a large optimum negative potential zone and (iii) a

smaller size (consequently, a better steric accessibility) – appear to be crucial for the molecules to form an energetically favourable complex with the receptor which would interfere with the subsequent reactions taking place in the receptor.

The computational results of this theoretical MESP analysis on the different conformers of acetaldehyde, nitrous acid and hydroxylamine indicate that three factors – (i) the magnitude of the deepest negative potential, (ii) a large 'optimum' negative potential zone and (iii) small size – would contribute largely towards their biological activity. The MESP analysis may thus be used as a tool to determine the degree of mutagenic capacity *vis-à-vis* deprotonating as well as deaminating abilities of these molecular mutagens.

Although electrostatic potential patterns shown in this study can offer a rich informative description about the capacity of the molecules to generate stereoelectrostatic forces, they fail to describe their ability to generate hydrophobic bonds and dispersion interactions. Therefore, the MESP profiles in the present investigation would reveal only the stereoelectronic components of intermolecular recognition forces. Thus, further sophisticated calculations including solvent effects are required to prove or disprove the proposed reasons for the biological potency of the molecules.

Record of 1.66-Ga-old marine oxido-reducing conditions from an unusual Sargipali Pb–Cu deposit (India): A preliminary appraisal through petrogenesis

Rajesh K. Vishwakarma

Department of Geology, Banaras Hindu University, Varanasi 221 005, India

In the Proterozoic marine reducing environment the evidence of oxidizing condition from petrogenesis of some unusual metamorphic rocks like calcite–brucite, quartz–diopside and diopside-rich skarn has not been reported. The results of this contribution imply that, despite complete alteration of their precursor sedimentary rock composition, there is little change in the original behaviour of the rare-earth elements. Primarily on this basis, information about the changing Proterozoic oxidation state in the reducing seawater environment is put forth on the basis of Ce anomaly. The observation may be significant in view of the worldwide rarity of data concerning oxido-reduction characteristics of the Proterozoic marine realm. In addition, a new documentary evidence for $\delta^{18}O$ and $\delta^{13}C$ isotopic depletion in the marble developed due to metamorphism of the pure dolomite rock under at least 600°C at 6 kb *PT*-conditions is also brought out. Until now it was generally believed[1] that the pure carbonate rocks do not show a net lowering of these isotopes under metamorphic conditions.

THE 1.66-Ga-old stratiform Sargipali sulphide deposit[2] of the Gangpur Group, eastern India (Figure 1), is a

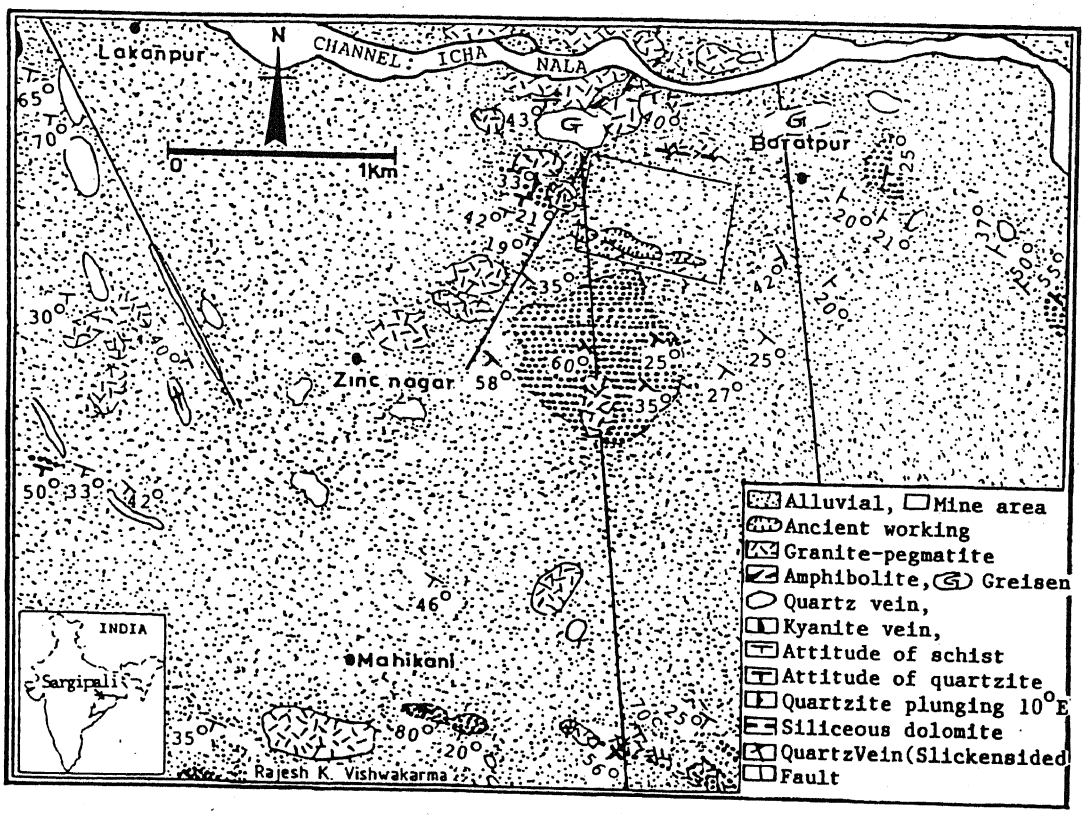

Figure 1. Geological map of the Sargipali Pb–Cu mine area. Inset shows the location of the study area.

syngenetic deposit which is formed due to sedimentary exhalative activity in response to the slow-spreading rift system[3]. Palaeoenvironmental study indicates that the area represents intertidal to supratidal marine flat environment[3]. This interpretation is based on polymictic metaconglomerate and current bedded structures (within meta-arenaceous lithounit), intercalations of quartzite, chert and carbonate skarn (within meta-argillaceous lithounit) and laminae of quartz–mica–chlorite within carbonate lithounit (Figure 2). These rocks are not included in the previous[5] stratigraphic scheme. Another interesting feature of the Sargipali deposit is the unusual Pb-rich mineralization with Cu association, which took place during deposition of the predominantly shaly sediments[4] (now represented by quartz–mica–chlorite schist, Figure 2) under reducing seawater environment. Lack of any contemporaneous oxidized facies around the ore body and the host quartz–mica–chlorite rock, the presence of thin pyrrhotite-rich bands in the deep mine levels, and the presence of graphite laminae in the ore and the gangue (Figure 3) collectively contribute to the idea of a reducing seawater environment. The present contribution, based on the study of petrogenesis of three rocks like marble, quartzite and skarn (which occur in the field as minor and impersistent lithounit), however, shows an evidence of oxidized environment during the formation of Proterozoic rocks in the area of study. Further, a geochemical evidence for the reducing condition is also being reported. Obviously, these findings are novel, since such type of data concerning this Proterozoic period remain rare worldwide.

The proposed programme has greatly benefited from the author's earlier work[4], in which a sufficient number of rock samples from various lithounits of the Sargipali area were analysed with respect to rare-earth elements (REEs). Out of these, three rocks, viz. marble, skarn and quartzite (which happen to be unusual on account of the mineral association presented in the following petrographic description), display a well-defined Ce anomaly. Therefore, the same is being reported and discussed as preliminary appraisal.

Furthermore, it may be imperative to point out that, although the analysed samples may not appear to be sufficient from statistical point of view, the REE trends represented by these analyses are quite logical and tenable in the light of the available literature. Hence, their utility is warranted in view of the fact[6] that sometimes, with the help of trace and rare-earth elements, geochemical modelling is possible even with one sample. With this assumption, a discussion on the above geochemical characteristics is made. But before this it is necessary to evaluate if the REE patterns of these

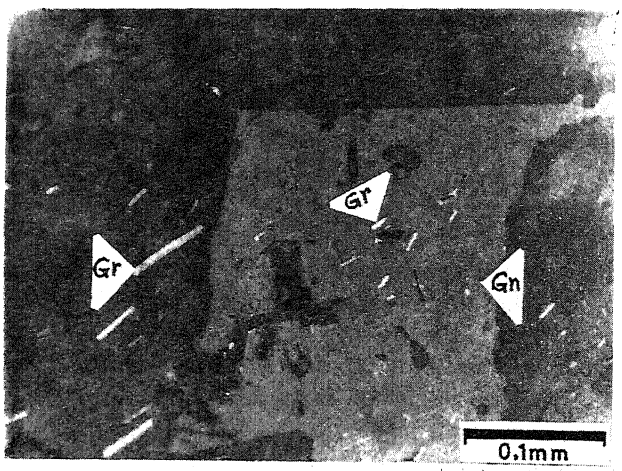

Figure 3. Occurrence of graphite in galena and gangue. Crossed polars. Specimen in oil. Gn = Galena, Gr = Graphite.

rock samples are at all representative of the original conditions of sedimentation, because the rocks have experienced multiple deformation, and also recrystallization over *PT* conditions of at least 600°C at 6 kb (ref. 4). To start with (i.e. the originality of REE pattern), the petrographic study is taken up. The *quartzite* sample, which has been collected from 'Mahikani' Hill, 4.6 km SSW to the prospecting mine (Figure 1), contains quartz and diopside as the major constituents; tremolite and zircon are minor while epidote is in the trace amount. Diopside occupies the intragranular space of quartz (Figure 4), containing noticeable amounts of zircon inclusions. Most likely, diopside in this rock represents a metamorphic equivalent of the initial impure carbonate which was mixed with initial quartz grains. It may, therefore, define a pure quartz sandstone, since in these rocks impure carbonate can occur as an irregular, scattered mass[7]. A provenance of this rock, as indicated by the total absence of feldspar and micas, could then lie chiefly with the quartzose sediment and/or the low-grade metamorphics of possibly quartzite. Petrographic study of *skarn* rock, which occurs as a thin laminate within quartz–mica–chlorite schist at 180 MRL of the underground mine reveals a calc-silicate mineral assemblage defined by diopside–tremolite–hornblende–chlorite–actinolite–calcite ± sphene. Here diopside is most abundant and, therefore, it can be a derivative of impure carbonate metamorphosed to amphibolite facies grade[8]. The petrographic study of *marble* (which is collected from its 2–3 inches thick concordant band in association with phyllite of the meta-argillaceous lithounit of the under-

ground mine at 120 MRL) reveals the groundmass of calcite to contain sometimes a minor patch of fibrous brucite. As a rule, this points to an original pure dolomite that upon metamorphism got decomposed and recrystallized to calcite and periclase with escape of CO_2 (ref. 9). In the presence of H_2O, however, periclase is transformed to brucite ($MgO \cdot H_2O$). This assessment, therefore, clearly agrees with the high MgO content of the analysed sample (Table 1). If it is so then the observed role of metamorphic decarbonation reaction is likely to disturb the reliability of the more sophisticated analytical data like $\delta^{18}O$ and $\delta^{13}C$ isotopes and REEs. Particularly, the isotopes of both $\delta^{18}O$ and $\delta^{13}C$ show a low value of -18.8 and $-11.01‰$, respectively (mean of three samples with respect to PDB), because CO_2 liberated could have been enriched in $\delta^{18}O$ as well as $\delta^{13}C$ relative to the carbonate[10]. On the other hand, compatibility of the REE data, particularly in relation to the precursor rock, is also a subject of examination, as follows in the ensuing discussion.

REE concentrations in the above rocks, obtained by inductively coupled plasma mass spectrometry with a precision of better than 7% relative standard deviation, are plotted as a REE pattern (Figure 5). Quartzite in this figure is rich in REE. This behaviour when considered in conjunction with the steep fractionated REE pattern may well represent a detrital origin of the rock. If this is true then, on the basis of the predominance of quartz, the rock can be conveniently assigned to sandy precursor; it is plausibly sandstone, because these are enriched in all REEs relative to chondrites[11,12]. Other samples, viz. marble and skarn, however, display depleted total REE with enriched heavy REE pattern (Figure 5). This behaviour not only corresponds to that of sediment but also suggests[11] that the rock is formed by the chemical precipitation process in marine environment. The reason behind the idea of marine hydrogenous origin lies in the fact that the above behaviour of REE is reminiscence of a low total concentration of REE with slight enrichment of heavy REE in seawater. In addition to this, it also appears that, although the rocks have evolved due to contact metamorphism, the magmatic water from the granitic stock did not introduce any large amount of REEs into the original rock compositions[13]. So, all these assessments may invariably support a general notion: the behaviour of REE during diagenesis and/or metamorphism indicate that there is little change in either the absolute abundances or the relative patterns.

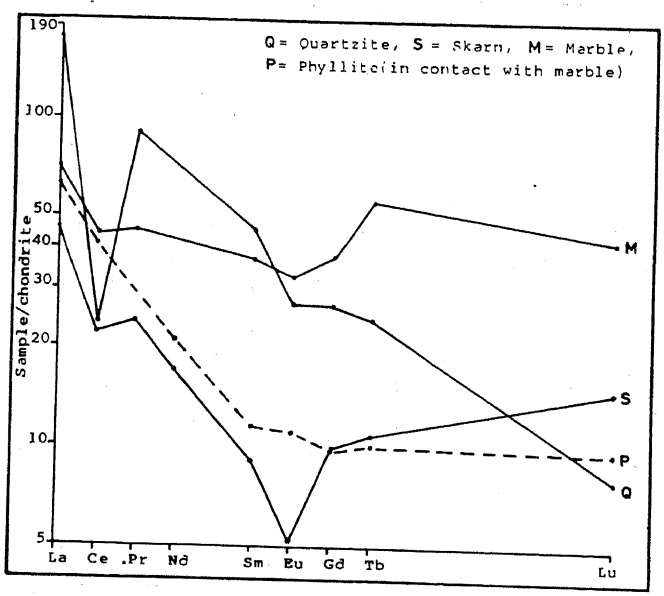

Figure 5. REE distribution pattern showing negative Ce anomaly in Sargipali quartzite, skarn and marble.

Nevertheless, in fulfilment of the reliability of the data, it is needed to bring out the factor governing minor Eu depletion in the studied samples (Figure 5). Critical to this, an effective way for removing Eu could have been the precipitation of $Eu^{2+}SO_4$. Such a mechanism is capable of removing most of the Eu while leaving most of the other REE[14]. If it is so, then at least most of the other samples formed in reducing conditions (e.g. quartz–mica–chlorite schist shown in figure 13 of Vishwakarma[4]) would have also yielded Eu depletion by this method. On the contrary, all these samples show positive Eu anomaly along with the steep fractionated REE pattern, and the features are actually, 'supplementary' evidence to charnockite provenance[4]. Here it may be annotated that by virtue of an evidence of the least Eu enrichment in the phyllite sample (Figure 5), which contains disseminated graphite, it cannot be invoked straightaway that the reducing conditions are prone to the formation of detectable Eu anomaly. Over and above, it is also not possible to propose removal of Eu anomaly due to remelting[15] or due to the influence of metamorphic fluid–rock interaction[16]. Likewise, the introduction of an oxidizing environment too has not a discernible effect on the behaviour of Eu[17]. Therefore, it seems that Eu anomalies in the samples of this study actually reflect an inherent property of their precursor. With this there remains no doubt that the REE patterns of the rocks are fairly representative of original sedimentation, and hence the observed feature of negative Ce–anomalies may be useful in providing an insight into the marine water condition during the formation of the rock[12, 17–20]. If this water is in an oxidizing condition, a smaller fraction of Ce will be trivalent, therefore resulting in Ce-depleted water condition and in turn Ce-depleted REE pattern in the marine sediments[19]. This scenario could have set in by the oxidation of Ce^{3+} under conditions of strong chemical complexation. Particularly, carbonate complexes of Ce^{4+} are the ones that control Ce in marine water (Möller, 1992, personal communication). Alternatively, according to experimental studies[21, 22], it is the oxidation of Ce^{3+}, into CeO_2 that causes Ce deficiency. This, therefore, corroborates the original idea of Goldberg[18]. The present study also reckons this observation in the light of the following. Phyllite (Figure 5) and quartz–mica–chlorite schist samples (Figure 13 of the earlier study[4]) both indicate a reducing environment of formation. So, for the obvious lack of oxygen, Ce removal by formation of CeO_2 could not take place, and as a result there remains normal La/Ce ratio, that is to say, normal REE pattern (Figure 5). Furthermore, the intensity of Ce anomaly observed in the present study is variable. Most likely, it is attributable to the quantum of the small fraction of Ce^{3+} which is left in an overall oxidizing marine condition.

ACKNOWLEDGEMENTS. Lt. Col. (Dr) V. Vishwakarma, Mrs Shail and Mrs Mohini encouraged me, and M/s Hindustan Zinc Ltd provided field work facility. Dr A. V. Ulabhaje, Prof. P. Möller and an anonymous referee reviewed the earlier write-up; Profs. R. K. Lal and S. G. Karkare helped in the petrographic study and major oxide determination, respectively; Drs S. M. Naqvi and V. Balram from NGRI and Mrs Kamlesh Agrawal from ONGC were courteous in helping me out with REE and isotope analyses, respectively; Dr N. Krishna Rao provided the facility for literature survey and ore microscopy; and a CSIR fellowship assisted me financially. I am grateful to all.

Characterization of humic acids isolated from soils under mulberry vegetation

R. Kar, R. N. Dutta and S. K. Majumder

Section of Soil Science and Chemistry, Central Sericultural Research and Training Institute, Berhampore 742 101, India

Two different samples of humic acids were isolated from soils under mulberry vegetation. The isolated acids have been characterized by electrometric (potentiometry) titrations and visible spectroscopy with a view to probing their physicochemical properties. Attempts have also been made to correlate the results obtained from these experiments with coiling–decoiling behaviour as well as aliphatic–aromatic balance of the acids.

HUMIC acids are nothing but the natural polymeric acids having complex molecular nature[1]. Characterization of the same is necessary, not only for having some information about their structural arrangements, but also for the effective use of these substances in mulberry cultivation[2]. The principal features of humic acids – the polyelectrolytic behaviour and coiling–decoiling phenomenon – are probed in detail in the present paper by looking at different properties of two humic acid samples isolated from soils under mulberry vegetation located at two different agroclimatic conditions.

For isolation of humic acids, soil samples were treated with sodium carbonate, followed by acidification of the alkali-extracted material with dilute HCl to pH 2 (ref. 3). The purified humic acids were denoted as HA_b (humic acid sample isolated from the soil under mulberry vegetation of Central Sericultural Research and Training Institute, Berhampore, Gangetic alluvium of West Bengal, 24°4′ N–88°9′ E) and HA_k (humic acid sample isolated from the soil under mulberry vegetation of hill nursery, Kalimpong, West Bengal, 27°2′ N–88°17′ E).

Potentiometric titrations were carried out by using standard NaOH solution. Carboxylic and phenolic –OH group contents were reckoned from the acidity equivalents of the initial and final inflexion points of the titration curves[4]. The amount of fresh alkali required to attain a stable higher pH, following a fall in the final pH (on standing after initial titration), as well as the time elapsed for the same were also recorded for each sample.

The optical densities at 465 nm and 665 nm (ref. 1) for the humic acid solution (Na form) were noted with the help of a systronics spectrophotometer at two different pH values 7.0 and 9.0.

Table 1 records the carboxylic and phenolic –OH group contents and a pH difference namely, $\Delta pH = pH_{3/4} - pH_{1/4}$, where $pH_{1/4}$ and $pH_{3/4}$ refer to the values corresponding to one-fourth and three-fourths of the final inflexion points. The ΔpH values of the humic acid samples are greater than 0.954, which signifies the polyprotic nature of both the acid samples[5]. Again, the approximate charge density (number of charges per unit mass) of humic acid molecule is computed from the cumulative contribution of carboxylic and phenolic –OH contents. This, in turn, governs the 'adsorptive capacity' of humic acid molecules, which enables them to combine with metal ions, clays, pesticides, fertilizers and different organic compounds[6,7]. HA_k is found to be superior to HA_b in this aspect.

The amount of fresh alkali needed to attain a stable higher pH as well as the time required for the same have been reported to be correlated with the coiled nature of humic acid molecule[8–10]. Addition of fresh alkali for stabilizing the higher pH (when HA molecules were completely unfolded) indicates an amount of remainder hydrogen ions which are not accessible to alkali initially. This, in turn, is governed by the steric hindrance associated with a particular conformation of the molecules due to their coiled shape. Thus, for higher degree of coiling, greater amount of fresh alkali is

Table 1. Potentiometric information about HA samples

HA sample	Amount of COOH (meq · g^{-1})	Amount of phenolic –OH (meq · g^{-1})	Approximate charge density (Number of charges g^{-1}) × 10^{-20}	pH at first inflexion point	pH at final inflexion point	ΔpH	Conclusion
HA_b	1.63	4.14	34.73	8.72	9.48	4.74	Polyprotic
HA_k	4.03	6.05	60.68	7.96	8.66	4.33	Polyprotic

Table 2. Potentiometric stability and spectrophotometric analysis of HA samples

HA sample	Amount of fresh alkali required to attain stable pH (meq · g^{-1})	Time required to attain stable pH (h)	E_4/E_6 at pH		$\Delta E_4/E_6$
			7.0	9.0	
HA_b	0.87	23.00	3.32	2.75	0.57
HA_k	13.12	69.50	4.88	4.07	0.81

required. Again, the time required to attain a stable higher pH depends on the ease of decoiling, which is inversely related to the intramolecular hydrogen bonding. Formation of such bonds is often interrupted by the alkyl groups available in the humic acid molecule; this, in turn, governs the 'flexibility' of the molecule. Thus, poorer flexibility exhibits longer time requirement. From Table 2 it may be concluded that HA_k is more coiled but less flexible than HA_b.

The spectrophotometric analysis data have been recorded in Table 2. The E_4/E_6 values, being greater than unity at both pH values, establish that the absorbance by the aliphatic part (i.e. absorbance at 465 nm) is greater than that by the aromatic part (i.e. absorbance at 665 nm) due to a particular conformational arrangement of the aliphatic and the aromatic moiety[1,9].

Table 2 also shows the data on $\Delta(E_4/E_6)$ ratio, namely, $\Delta(E_4/E_6) = (E_4/E_6)_{pH-7} - (E_4/E_6)_{pH-9}$. The latter may be taken as an 'index of coiling' of the humic acid molecules owing to the fact that addition of alkali (NaOH) rendered the acid molecules 'unfolded under thermodynamic compulsion'[11]. This leads to the destruction of the tertiary structures (i.e. three-dimensional configuration) of the molecules following the release of the hidden aromatic parts, which thereby leads to a lowering of E_4/E_6 value, giving a positive value of $\Delta(E_4/E_6)$.The higher $\Delta(E_4/E_6)$ value of HA_k signifies that the latter is more coiled than HA_b. This has got close resemblance with potentiometric study discussed earlier. It may further be concluded that HA_k is more aromatized than HA_b.

Research Accounts

Current Science intends to start a new feature entitled 'Research Accounts'. Articles in this category are intended to be personalised reviews of research from the authors own laboratory, based on a body of published work. The articles must provide appropriate background to the area in a concise introduction, which should also serve to place the author's work in proper perspective. A concluding section may address future trends and directions in the area. Unpublished results may be included only when absolutely essential and should be kept to a bare minimum. Articles in this category may be about 20 double spaced typed pages; A4 size (8–10 printed pages) and should include appropriate illustrations. References to the literature should not number more than about 60. Articles should address a broad readership. While most articles in this category will be solicited by the editors, unsolicited contributions will also be considered. All articles will be reviewed by two independent referees. Authors are encouraged to suggest appropriate reviewers.

Contributions to Operator Theory and its Applications. T. Furuta, I. Gohberg and T. Nakazi (eds). Volume 62 in the series Operator Theory: Advances and Applications, Birkhäuser, P.O. Box 133, elt 4010. Basel. 1993.

The name Tsuyoshi Ando is well known to research workers in functional analysis, operator theory, linear algebra and the mathematical theory of networks and systems. This volume consists of thirteen papers in these areas dedicated to Ando on his sixtieth birthday. A brief biography of Ando and his list of publications is also provided.

Since the papers in this book are on diverse problems, the best way to review it might be to give the reader a general idea of some of the topics covered, with particular reference to the work of Ando.

Let $\mathcal{H}$ be a Hilbert space contained in a larger Hilbert space $\mathcal{K}$. An operator T on $\mathcal{K}$ is called a *dilation* of an operator A on $\mathcal{H}$ if T can be written as

$$T = \begin{bmatrix} A & B \\ C & D \end{bmatrix}$$

when $\mathcal{K}$ is decomposed as a direct sum of $\mathcal{H}$ and its orthogonal complement. The operator A is then called a *compression of T*. A *dilation theorem* is a statement that certain operators can be dilated to 'nicer' operators on a bigger Hilbert space. For example, if A is a contraction ($\|A\| \leq 1$) on $\mathcal{H}$ then

$$U = \begin{bmatrix} A & (1-AA^*)^{1/2} \\ (1-A^*A)^{1/2} & -A^* \end{bmatrix}$$

is a unitary operator. This is a generalization of the elementary fact that if a is a real number and $|a| \leq 1$ then

$$\begin{bmatrix} a & \sqrt{1-a^2} \\ \sqrt{1-a^2} & -a \end{bmatrix}$$

is a rotation matrix. Thus, *every contraction has a unitary dilation.*

If A is a contraction then so are its powers A^n, $n = 1, 2, \ldots$. Each of them will have a unitary dilation. It is somewhat surprising that there exists a single unitary operator U such that U^n is a dilation of A^n for all n. This is a famous theorem proved by, Sz.-Nagy in 1953. (The discrete variable n here can be replaced by a continuous variable t: every contraction semigroup can be dilated to a unitary semigroup).

Results such as this are typical in dilation theory, now a major subject. One of the famous results of Ando, proved in 1963, says that a *commuting pair of contractions can be dilated to a commuting pair of unitaries,* i. e., if A_1, A_2 are commuting contractions, then there exists commuting unitaries U_1 U_2 such that for all positive integers n, m, $U_1^n U_2^m$ is a dilation of $A_1^n A_2^m$. In 1970 it was proved by Parrott that an analogue of this for three or more commuting contractions is false. The *commutant lifting theorem* to which this line of work ultimately led has been found to be very useful in the theory of linear systems.

Let P_1, P_2 be two projection operators in a Hilbert space. Long ago, von Neumann observed that the infinite product $(P_1 P_2)^n$ converges to the projection operator whose range is the intersection of the range of P_1 and P_2. In 1961, Burkholder and Chow proved that the same is true for any finite number of projections $P_1, P_2, \ldots, P_k$, and when the Hilbert space is L^2 and the projections are conditional expectations then the convergence takes place not only in the strong (L^2) topology but also pointwise, almost everywhere. In a different direction, Amemiya and Ando proved in 1965 that if $T_1, \ldots, T_k$ are contractions then any *random* product $T_{i_1} T_{i_2} T_{i_3} \cdots$ of elements chosen from $\{T_1, \ldots, T_k\}$ converges weakly. Such results are closely related to problems in ergodic theory, dynamical systems and computer tomography.

The arithmetic, geometric and harmonic means of positive numbers are familiar objects. Lots of interesting difficulties arise in defining similar means for positive Hilbert space operators, because of the noncommuting nature of the variables. Such means are of interest in quantum theory and also in the theory of electrical networks. For example, the parallel sum is just one half of the harmonic mean. Ando has studied such objects in great detail. In a paper with Kubo in 1980, he gave an axiomatic characterization of such means. In a very interesting paper (which drew this reviewer to his work) Ando used these ideas to give a simple proof of a theorem of Lieb that established the Wigner–Yanase–Dyson conjecture about the concavity of entropy in quantum mechanics.

From the late seventies, much of Ando's work has been on matrices, specially on matrix inequalities. He has mastered the techniques of majorization and the theory of operator monotone functions, and used both of them in spectacular ways to prove delicate and elegant inequalities for operators and matrices.

The book under review has papers on many of the problems to which the work mentioned above leads. It would be of interest to anyone working in these areas.

Science in Society: Some Perspectives. Yash Pal, Ashok Jain and Subodh Mohanti eds. NISTADS, Dr K. S. Krishnan Road, New Delhi 110 012. 405 pp. Rs. 400.

This handy anthology starts with a magnificent introduction from Prof. Yash Pal; he leads off the discussion with a characteristically brilliant and thought-provoking statement, as arresting as it is pithy. The lead sentence 'the difference between science and society and science in society is very important for me' sets the mood and the direction for all the essays in the book although not all of them reach the standard of clarity of thinking or of focused purpose that illuminate Yash Pal's lead. The book demonstrates congruence of views and should provide the basis for concerted action, review and mid-course corrections in policy.

One difficulty that an average reader will find is that the book bears no explicit reference to the year in which these essays have been prepared and no indication if some of the initiatives mentioned are under implementation or if they are mere expressions of hope (the case of INFLIBNET is a clear case in point). Some of the articles would have been more convincing if they had included some idea of costs to the user. An epilogue to show how far the movement initiated by Yash Pal in the 77th Indian Science Congress has developed momentum would have been useful.

Science in society

Yash Pal leads the way with a complete statement of the case for 'science in society'. Three quotes would give the reader an insight into what to expect: 'science should not be treated as an additional activity or a tool ... instead it should be treated as part of the culture of society, integral to our thinking ... connected with our dreams, connected with concepts of ethics, beauty and spirituality', 'if we make science as a part of our culture they (benefits) would all come, much more naturally, more creatively and *more in tune with our living, not as an assault from outside*', 'in science and technology you cannot imbibe the true spirit of the craft *unless you do some things on your own*, do your own inventing'. Yash Pal covers a wide territory: the value of innovations to true development, the imperative need to invest in education if S & T (science and technology) R & D is to be supported, an equal emphasis on investments in S & T and in science education. There is a touch of humour in his development of the relationship of ethics and law in an age of 'technological exuberance': he says that 'it was not unethical 500 or 1000 years ago to throw your muck into the Ganges ... because Ganga had sufficient powers to purify it'.

Many of the contributors clearly link their contributions to 'science in society', the absorption of science as an integral part of our culture. The contributions can be divided into three categories: those with a philosophical flavour representing *cultural absorption*, those with plans and ideas to *involve the population* in developmental activities as a practical illustration of how 'science in society' could operate, and those which demonstrate *vigour in scientific thought and practice* and induce in the reader a sense of optimism that Yash Pal's vision can indeed become a reality.

Cultural absorption

Pushpa Bhargava and Chandana Chakrabarti see a commonality in the origins of the creative urge in scientific and artistic works, describe practitioners of art and science as seekers of beauty and assert that both (art and science) 'are becoming increasingly interdependent in terms of materials, ideas and ideals'. In a fine essay 'The symphony of symmetries', Babu Joseph points to developments in the study of open systems which 'include the whole living world as well as most nonliving things'. His development of ideas on 'spontaneous symmetry breaking' as the mechanism of growth and decay should be fed into the curriculum for science at several levels with increasing depth of presentation. Ashok Parthasarathi's coupling of nonalignment, self-reliance and innovation gives practical shape to 'science in society' (particularly Yash Pal's call for 'doing something on your own') and brings policy-making into focus. In particular, his declaration that 'while it is true that S & T intersect at many points, the intersections are less and less matters of accident and more and more matters of design in terms of policies and programmes' deserves the basis for nonpartisan policy-making. Another very interesting articulation of the concept of 'science in society' is the use of energy as a measure of programme content (C. V. Seshadri), which leads to sustainable development through the blended use of resources combining development with avoidance of environmental degradation. D. P. Chattopadhyaya's article draws attention to the two faces of technology: estrangement and enlargement, and emphasizes the need for an awareness of the consequences of the use of technology. His is a timely call for 'workers and thinkers to control technology and institutions more effectively than they can control us'. A similar warning on the impact of technology on society comes from V. Sudarsen, who calls for alternative paradigms of development citing the irony of continuity in the pursuit of an imperial forest policy even after independence. He warns against the disregard for social consequences and asserts that 'technological progress is not necessarily axiomatic for development processes'. Ashok Jain echoes this thought with 'environmental crisis is a sign of saturation of the conventional paradigm'.

Precept and practice

Jayant Narlikar's fine essay 'Education through astronomy' will find an echo in many whose introduction to astronomy was wholly through gymnastics in integral or differential calculus. Equally well-correlated to the theme of the book is V. G. Bhide's note on interuniversity centres; he is the lone author tracing lack of a clear career path (salaries included) as one major cause of student apathy. He also relates the government-inspired and organized techniques to the dual demands of the 'product of science' and the 'process of science'. His essay is the kind of core strategy that matches the vision of 'science in society', catching them young as it were. Vinod Raina's article describing a programme of the 'People's science movement' is an excellent example of how a concept can be translated into practice and harmonized with the circumstances in a given location. This article should give a fillip to the emergence of more initiatives of the kind. M. S. Swaminathan's contribution 'Biotechnology and ecological security' is scholarly and practical, introducing us to the concept of 'ecological security'. His article is an outstanding example of how a versatile mind can be ahead of formalized thought. His suggestions and ideas on directions of development give practical content to the concept of 'science in society' through the fusion of physical and social sciences to produce worthwhile and commercially viable goals.

Excitement of science

The articles on scientific projects (earthquakes, monoclonal antibodies) reveal the capabilities of vigorous research in India but the authors would have expanded their audience reach if they had explained the techniques and results in layman terms. The sense of excitement in science needs to reach young minds in as many directions as possible. For example, apart from publications intended for professional journals exclusively dedicated to research material, can we not think of articles on S & T that describe briefly, or at least enumerate, the different technologies on which the conduct of an item of research or production of specified goods and services depend? Such articles would show young enquiring minds what career path options in S & T may be available for them to choose from, and also infuse in them a sense of team-orientation in S & T work.

A strong public opinion is the proper basis for the percolation of the 'science in society' concept and its acceptance. The editors of the book have rendered a great service by bringing out this volume

in order to catalyse this process. Broad-based initiatives which bring the concept into practice using local resources would be necessary. This also suggests that research effort is needed for the evolution and adoption of organizational structures suitable for the task on hand in the region where the initiative takes shape. The apparent apathy in 'science in education' can be overcome only through multiple techniques and structures. Perhaps the disavowal of the editors about the book not being a 'cogent articulation of various tenets' clearly recognizes the need for further effort. The mention of a 'think tank' might draw cynical expressions of elitism but the time is opportune for one or more 'think tanks' to address these issues and develop a menu of options to carry Yash Pal's lead concepts onward; local groups could choose their strategy from this menu for use as suits circumstances in their area. The ideas sprouting from the studies will motivate policy-making at governmental and other levels. This should lead to the gradual infusion of science in national culture. Thoughtful leaders of public opinion (of the kind who have contributed to this book) should also find out how the stated objective could be reached in an environment of limits to the efficacy of governmental patronage.

S-23 Golden Enclave
Airport Road
Bangalore 560 017, India

Annual Review of Cell Biology 1994. J. A. Spudich, S. L. McKnight, R. Schekman, eds. Annual Reviews Inc., Palo Alto, California, USA. vol. 10. 478 pp. Price: USA $ 49; elsewhere $ 54.

Cellular biology continues to grow and diversify, encompassing the broad areas of biochemistry, genetics and molecular biology, in order to obtain an understanding of the inner working of the cell in molecular terms. These endeavours have now been extended to the study of whole life forms, as topics in developmental biology find a larger representation in this volume of *Annual Review of Cell Biology*, paving the way for a formal merger of these two disciplines from 1995 onwards, when the name of the series will change to *Annual Review of Cell and Developmental Biology*.

The pathways that control cell growth and differentiation, in mammals in particular, are undoubtedly complex. Recent progress in this field has been remarkable and five reviews are devoted to advances in the broad area of cell regulation. In a lucid article by D. J. Riley and coworkers on the retinoblastoma protein, the properties of this key regulator of cell division have been discussed. In the normal cell cycle, activated retinoblastoma protein restricts further cell proliferation. However, binding of oncogene products to this protein can block its activity and lead to unscheduled cell division, resulting in malignancy. U. Siebenlist and coworkers have reviewed the structure and functions of the transcription factor NFκB family of proteins, which serve to coordinate the rapid induction of a range of defence genes in the immune system. A unique feature of NFκB is its rapid translocation from the cytoplasm to the nucleus in response to extracellular signals, and the complexities of this process have been analysed in depth.

Signal transduction pathways in the cell basically depend on the fine tuning of phosphorylation of specific proteins by kinases and phosphatases. P. van der Geer and others have given a detailed account of a major class of transmembrane receptors called the receptor protein–tyrosine kinases. Studies on these kinases have contributed significantly to an understanding of how cells are regulated by extracellular signals. S. Shenolikar has written a comprehensive review on the protein serine/threonine phosphatases, highlighting their physiological functions and cellular regulation. A group of proteins that play a crucial role in signal transduction pathways are the GTPases. T. A. Glomset and C. C. Farnsworth have documented the different posttranslational modifications found in these GTPases (such as farnesylation of the carboxy terminus and acylation of the amino terminus) and presented evidence for their role in determining the interactions between the GTPases and the cell membranes. Additional studies are required before the functions of these modifications are firmly established.

In the area of intracellular sorting of proteins, which found exhaustive coverage in last year's volume, there is a single review on protein targeting to the endoplasmic reticulum by P. Walter and A. E. Johnson, which emphasizes the common steps in targeting in eukaryotes and prokaryotes. However, the mechanism of translocation of the nascent protein across the endoplasmic reticulum remains less well-defined.

The cytoskeletal framework of the cell, for long a favoured topic for cell morphologists, is emerging as a dynamic and complex structure, subject to a variety of regulatory phenomena. Five reviews are devoted to recent developments on the structure and function of cytoskeletal and associated proteins. A. Hall has contributed a highly topical review on the regulation of the actin cytoskeleton in response to extracellular signals through the ras family of small GTP-binding proteins. A comprehensive review on the three-dimensional structures of 12 actin-binding proteins has been provided by T. D. Pollard and others. E. L. F. Holzbaur and R. B. Vallee have discussed the recent findings on the structure and functions of dyneins, one of the largest and most complex motor proteins. A major class of cytoskeletal proteins, the microtubules, are involved in cellular elongation and cytokinesis. Their role in cellular patterning in the growing plant has been elegantly discussed by R. J. Cyr, who has also presented a hypothesis for the mechanism by which microtubules bring about cellular elongation.

Vertebrate limb development has been one of the best-studied systems for understanding cell and tissue patterning, mechanisms of innervation, cell differentiation, angiogenesis and programmed cell death. C. Tickle and G. Eichele have reviewed the embryological data on limb patterning, and presented recent work that has begun to unravel the molecular responses to signalling molecules involved in the process.

Intensive research on the mechanism of Alzheimer's disease has led to the identification of cerebral deposits of the amyloid β protein as the causative agent of the disease. D. J. Selkoe has reviewed the cell biology, in particular the intracellular processing, of the amyloid β protein precursor. Several mechanisms have been proposed for the eventual imbalance between amyloid β protein formation and clearance which results in

amyloid deposits. Pharmacological intervention in the disease process is being attempted at various points along the amyloidogenic pathway, and may have the potential of being used to slow down the gradual accumulation of amyloid deposits that accompanies normal aging of the human brain.

This volume of the *Annual Review of Cell Biology* truly 'unifies a diverse and rapidly expanding field'. The reviews are selective and critical in format rather than exhaustive. An essential book for all researchers in cell biology.

VEENA K. PARNAIK

Centre for Cellular & Molecular Biology

Environment and Adaptive Biology of Plants. Professor David N. Sen Commemoration Volume. D. D. Chawan, ed. Scientific Publishers, 5A, New Pali Road, Jodhpur 342 001, India. 1995. Price: Not known. 322 pp.

Environment and adaptive biology of plants is one of the topics of past, present and future scientific interest. Much of the progress we have made in crop selection and breeding have stemmed from basic understanding of plant adaptation to environmental conditions. The success of introduced agricultural, horticultural and timber plants all over the world, ever since humans began transporting them, has also been a result of our knowledge of plant adaptability to different environment.

Current interests in plant adaptive biology worldwide are in the areas of (1) *in situ* protection and management of endangered plants, (2) sustaining productivity in crop plants, (3) identifying locally evolved resistance to pests, diseases and other environmental stresses, (4) reclamation and revegetation of degraded landscapes and (5) management of increasing salt and water stresses in coastal and semi-arid zones.

Considerable progress has been made in the above fields of environmental science both in India and abroad. Our knowledge of dioecious plants (especially in the genus *Garcinia*) being capable of reproducing apomictically on isolation is helpful in the management of threatened species. Case studies of such plants shed light on survival strategies that isolated plants adopt at the expense of genetic variability. Land races that are locally adapted are in much demand today for crop improvement and sustainable agriculture. Most recent interest has been in understanding the mechanisms plants have adopted in dealing with salt stress. Of special importance in this regard are the estuarine plants, commonly referred to as mangroves. Mangrove plants in the genus *Rhizophora* are known to localize the salt in the root zone itself. These plants, which are also capable of withstanding flooded conditions, can be the answer to ecological problems that might arise in the event of the anticipated sea level rise. Research on the physiology and genetics of mangrove plants is under way, especially in an effort to identify 'plus' trees (supertrees which can withstand considerable amounts of environmental stress). A major programme in this field of interest has been on at the M. S. Swaminathan Research Foundation, sponsored by the Department of Biotechnology, Government of India.

The book under review is the most unusual blend of biography, science, documentation and advertisement. The book is divided into six parts, viz., (1) Ecology and environment management, (2) Adaptive biology, (3) Biology of saline plants, (4) Weed biology, weed management and allelopathy, (5) Desertification and agroforestry and (6) Environmental pollution. Two to five papers have been included under each of these major parts. These papers vary in style from being introductory to highly structured experiments and results, making reading rather uncomfortable. Papers have not been appropriately grouped. For instance, Part 1 includes an ethnobotanical document which merely lists plants used by natives in the Narmada valley. Similarly, in Part 4, one paper provides a detailed list of weeds associated with crop fields of Madhya Pradesh without any reference to management.

The strength of this book, however, rests in Part 3, which discusses a topic of current scientific interest. It appropriately includes papers on mangrove plants and those in salt-prone deserts of India. Although the discussions fall short of being comprehensive, the papers are more in tune with the broad title of the book than the rest.

The book, in general, fails to address current issues relating to the environment and adaptive biology of plants. All detailed discussions included have emerged from laboratory studies paying little attention to field conditions. Most papers are not even state-of-the-art treatises of the concerned science, not even of that in India. To a serious student of plant adaptive biology, the book can well prove disappointing.

A pioneer in modern plasma physics

An obituary of Hannes Alfvén

Professor Hannes Olof Gösta Alfvén, a renowned space physicist and a prime contributor to the field of magneto-hydrodynamics, died on 2 April 1995 at his home in Djursholm, Sweden, at the age of 86. With his passing away, the world of physics has lost a highly creative and original physicist. He can justifiably be called one of the pioneers of modern plasma physics – a field of study that finds applications in a wide range of areas such as cosmology, astrophysics, controlled thermonuclear fusion, radio communication, etc. Alfvén's contributions and insights into the field, especially during its infancy, are many and bear the stamp of his remarkable physical intuition. He developed very powerful tools which greatly aided the analysis of complex physical phenomena and advanced the field in giant steps.

An early example of such a powerful idea is that of the concept of frozen-in flux, where the plasma is considered to be tied on to the magnetic lines of field that pass through it. Alfvén discovered this theorem in the early 1930s and used this simplifying tool to great advantage in solving many space physics problems. In fact, so successful was this paradigm that it began to be used indiscriminately by many later workers in the field, who applied it to situations where its validity conditions were often violated. Alfvén expended considerable effort in educating the scientific community about the proper validity conditions of this theorem. Another simplifying notion that Alfvén invented was the guiding centre approximation, by which the complex orbit of a charged particle in a magnetic field could be calculated in a very simple manner in terms of the motion of the centre of the Larmor motion and its drifts. The physical notion underlying this idea is that of the equivalent magnetic moment associated with the spiral motion of the charged particle. This concept helped him understand many complex phenomena associated with auroras, magnetic storms, cosmic ray generation in the solar system and in the interstellar space. In the laboratory, this concept helped in the development of some early practical devices like the trochotron, a high vacuum switching tube, and in later years the idea of the invariance of the magnetic moment was at the heart of the plasma confinement in mirror machines. Today some of these tools invented by Alfvén have become such standard repertoire of plasma physicists that we hardly pause to contemplate their power and simplicity or to imagine the difficulties of working without their aid.

His most well-known discovery – that of hydromagnetic waves, which are commonly called Alfvén waves – is another prime illustration of the power of his physical intuition. In thinking about the problem of sunspots, he reasoned that they consisted of magnetic fields embedded in the highly conducting solar plasma. These magnetic fields must arise from currents flowing in the plasma and the mutual interaction between them must make both the currents and the fields to move. Thus on purely physical grounds he worked out the theory of this movement – that of an electromagnetic wave – propagating through a highly conducting medium. At the time when he published his theory in *Nature* in 1942, nobody believed it. It took many years for scientists to accept this idea. The common notion at the time, from the well-known Maxwell's theory, was that an electromagnetic wave could scarcely penetrate a conductor. Thus, Alfvén's proposition of an electromagnetic wave propagating in a perfectly conducting medium with no attenuation seemed physically impossible. It was only in 1948 when Alfvén visited the United States for the first time and lectured about his work at a number of places that the correctness and significance of his work was recognized. According to an apocryphal story, when Fermy heard his lecture at the University of Chicago, he nodded his head and said, 'Of course'. The next day the entire world of physics said, 'Oh, of course'.

Alfvén was also the first person to suggest the existence of large-scale magnetic fields in the galaxy. This was soon after it was discovered that cosmic rays were charged particles and not gamma rays filling the entire universe. This spurred Alfvén to create a self-consistent picture of electrical currents flowing in a low-density plasma pervading the galaxy, giving rise to large-scale magnetic fields and the cosmic ray particles moving in spiral orbits about these fields. These ideas, which are well proven and accepted today, were way ahead of their times in the late 1930s when interstellar space was supposed to be a vacuum and could not support any currents. In 1939, he also proposed a remarkable theory of magnetic storms and the aurora in which he introduced several novel concepts, including that of the guiding centre approximation, the concept of electric field drift for plasma within the geomagnetic field and the concept of a ring current formed from quasi-trapped radiation. He preceded Fermi in suggesting a mechanism for cosmic ray acceleration and also provided the right tools for understanding phenomena such as the Van Allen radiation belts.

Alfvén's intuitive approach was often in conflict with the prevailing style of doing science with idealized mathematical models which could be solved exactly. Thus, he often faced difficulty in publishing his papers. But his first book, *Cosmical Electrodynamics*, published in 1950, in which he collected much of his early work, had a great impact in the development of space physics and plasma physics. This development also vindicated many of the fundamental concepts introduced by him. Thanks to his pioneering contributions, the theory of magnetohydrodynamics has today become an established and well-developed branch of physics and is widely used in the field of astrophysics and fusion physics.

Alfvén was acutely aware of the importance of technological developments leading to the creation of new fields for scientific investigations and believed that 'the centre of gravity of the physical sciences is always moving'. He was thus an active supporter of newer space experiments and advances in fusion devices. He also believed in small-scale laboratory experiments to test basic concepts and promoted actively the development of such programmes in the institutions that he was associated with. Some of them carried out remarkable fundamental

experiments in plasma physics, often in the form of verification of some of his own ideas. For instance, in developing a comprehensive theory for the evolution of the solar system, Alfvén intuitively proposed the concept of a critical relative velocity between a neutral gas and a magnetized plasma. Beyond this velocity the gas would ionize rapidly and the resulting plasma cloud would form the starting point for the process of condensation and accretion, leading to the formation of secondary bodies like planets and satellites. The value for the critical velocity was proposed to be $(2eV_i/M)^{1/2}$, where V_i and M are the ionization potential and mass of neutral atom. This limit has been experimentally verified in a number of experiments, including some carried out at the Royal Institute of Technology in Stockholm under his active encouragement. Likewise, he inspired a series of experiments and developments on the Marshall gun – a plasma device to create a minimum magnetic energy plasma configuration which he had theoretically proposed. This concept in the advanced form of a Spheromak configuration is today considered to be an attractive fusion confinement geometry. His original idea of intense electric field structures in space led to a large body of theoretical and experimental investigation into the so-called potential double-layer formations. Alfvén also helped inspire some early plasma physics work in India when he visited the Tata Institute of Fundamental Research, Bombay, in 1958 at the invitation of Homi Bhabha and gave a series of lectures on plasma physics to the then fledging plasma physics group.

Not all his ideas are accepted even today. He has put forward his own theory of cosmology, opposing the big bang model, and leaning towards the cosmology of Oscar Klien, with a universe oscillating between expansion and contraction. He believed that the universe was formed as an ambiplasma (i.e. with equal amounts of matter and antimatter) and suggested clever mechanisms for their segregation into separate worlds. He also emphasized the importance of dust in the universe and talked long time ago about 'dusty' plasmas. Cast in the role of an iconoclast, during his early struggles with the established scientific views in space physics, Alfvén continued to question the established doctrine and always fought for his own 'wild' ideas. In the words of his friend and associate, Gustaf Arrhenius, Alfvén was a 'gentle wild man'. He was also an active campaigner against nuclear warfare and participated in the East–West 'Pugwash' conferences that sought to prevent such confrontations. Originally a strong promoter of nuclear power generation, he later grew apprehensive about the long-term safety of reactors and sought to highlight the problem of nuclear wastes. He continued to be active in research till fairly recently, sharing his time between the Royal Institute of Technology and the University of California in San Diego.

Alfvén was the recipient of several awards, including the Nobel Award in physics in 1970 (shared with Louis Neel), the Lomonosov Gold Medal of the Soviet Academy of Sciences, the Franklin Gold Medal of the Franklin Institute in Philadelphia and the Gold Medal of the Royal Astronomical Society, UK. He was a member of the National Academy of Sciences in the United States and a Fellow of the Royal Society in Britain. His books included: *Cosmical Electrodynamics*, 1950; *On the Origin of the Solar System*, 1954; *Cosmical Electrodynamics: Fundamental Principles* (with C. G. Fälthammar), 1963; *Worlds–Antiworlds*, 1966; *Structure and Evolutionary History of the Solar System* (with G. Arrhenius), 1975; *Cosmic Plasma* (monograph), 1981. He also wrote several popular scientific books, many of them in collaboration with his wife Kerstin Maria Erikson and often assuming the pen name of Olof Johannesson.

Alfvén has given the world of physics a rich legacy of ideas and tools. They have helped us reach out and understand many complex phenomena in the sun, the stars and the space beyond. They are also the basis on which one hopes to create the first star in the laboratory – and harness the energy of fusion reactions. Such is the power and reach of the field he helped create and which reflects in a striking way the true measure of his amazing genius.

Gandhinagar 382 424, India

Remembering Hannes Alfvén and his work

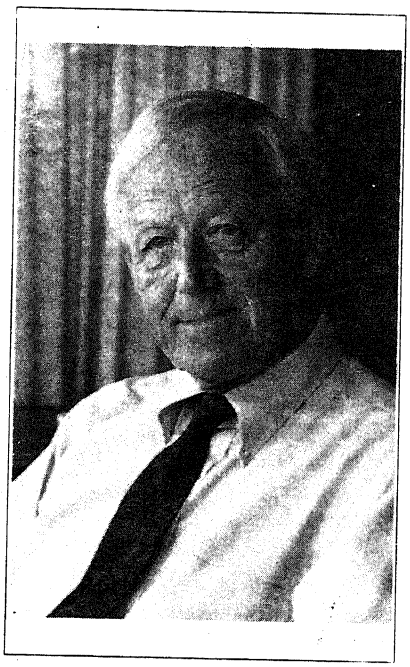
'You know I love your country and I do Yoga everyday', Professor Hannes Alfvén was telling me this in a conversation in Gothenburg, Sweden, at a Plasma Physics conference in 1988. He further added, on seeing the book *The Alfvén Wave*, the first book on this topic written by Akira Hasegawa from Bell Laboratories, NJ, USA and myself and dedicated to him, 'You both seem to know more these waves than myself'. This was the highest complement coming from Hannes Alfvén, who discovered the Alfvén waves in 1942.

He can be justifiably considered as the father of space plasma physics and astrophysical plasmas. He originated many key theoretical ideas which opened a new vision in understanding of the plasma universe. Hannes Alfvén received his Doctorate from the University of Upsala in 1934 and was appointed as Professor of electromagnetic theory and electric measurements at the Royal Institute of Technology, Stockholm, in 1940, at the age of 32. From this date to almost the end of his life, Alfvén was an active scientist of this laboratory. His vigorous scientific and administrative activities led to the creation of several new departments within the Royal Institute of Technology. Three of these, Plasma Physics, Fusion Plasma Physics and Accelerator Technology Departments now constituted a separate entity called the Alfvén Laboratory. His own chair evolved correspond-

ingly into electronics in 1945 and plasma physics in 1963.

From very early age, as a young boy Hannes Alfvén was intrigued by radio sets and radio electromagnetic waves. His vision about magnetic and electric fields and interaction with matter in the universe led him to discover the entirely new kind of waves in conducting fluids interacting with magnetic fields, which are now known as Alfvén waves. These waves have become a foundation stone in plasma physics and its applications to space physics, astrophysics and thermonuclear fusion plasma physics. In order to understand the theory of sunspots, Alfvén in a now famous letter to *Nature* gave a very simple mathematical formulation describing the mutual interaction between electromagnetic fields and conducting fluid motion and found that this interaction can give rise to a new wave phenomenon called electromagnetic–hydrodynamic waves.

Alfvén waves, as these waves are now known are low-frequency transverse waves propagating along the magnetic lines of force. Unlike sound waves, these are choosy about the direction of propagation. Closely related to the Alfvén waves is the concept of 'frozen in magnetic fields', also due to Alfvén. This concept simplifies greatly the physical reasoning about plasma phenomena but has its limitations. Using this concept it was very easy for Alfvén to draw an analogy with the theory of stretched strings. The magnetic tension arising due to parallel component of the Lorentz force along the magnetic field lines can lead to the possibility of transverse waves along the lines of force, with velocity ϑ_A given by



$$\vartheta_A = B_0/(\mu_0 \rho)^{1/2}$$

where ρ is the mass density of the fluid on which the field lines are imbedded.

The 'frozen in' concept, though simplifies greatly the physical reasoning about plasma phenomena, has its limitations. Alfvén himself cautioned the plasma physicists in using this concept without proper justification.

Incredibly, it took several years before the results arrived at by Alfvén were taken seriously. The experimental verification of Alfvén waves came still later due to technical difficulties. With the advent of space age now we have numerous number of satellite and spacecraft observations pointing out the omnipresence of Alfvén waves in space physical systems. The theoretical studies point out how various natural phenomena in nature can be explained as manifestation of the presence of Alfvén waves. In recent years the study of Alfvén waves in inhomogeneous magnetic fields have led to a considerable understanding e.g. of solar coronal heating, bending waves in galaxies, the characteristic features and origin of ULF waves in the magnetically organized systems, the magnetosphere, particle acceleration in auroras and so on.

The other natural phenomenon which attracted the attention of Hannes Alfvén

was the aurora. As we know auroras are a spectacular display of luminous radiation in the sky near polar regions. Auroras as we know from recent space experiments and theoretical developments are manifestation of the interaction of solar plasma with the earth's magnetic field. Much before these ideas were established Alfvén knew the key to the problem of understanding the auroral phenomena and in his very early years of research began to study the motion of charged particles in electric and magnetic fields. The guided centre approximation given by Alfvén to study the equations of motion of charged particles in electromagnetic fields led to the development of this subject and the important adiabatic theory for describing the mathematical models of plasma based on single charged particle motion. The importance of Alfvén work in this area can hardly be exaggerated.

Alfvén developed several other concepts regarding interaction of plasmas with magnetic and electric fields. Some of these were not well received initially but have later proved to be highly relevant and useful. For example, in a visionary paper published in 1958, he proposed auroral primary electrostatic potential drop along geomagnetic field lines. Such electric fields with huge potential drops were considered impossible at that time, but modern space probe measurements have established such electric fields and have also shown that this mechanism indeed plays a crucial role in the physics of aurora. Another example: as a part of a theory of the origin of the solar system, Alfvén introduced the daring hypothesis of 'critical velocity' in plasma–neutral gas interaction. Its experimental validation came years later, and it took many years more before the mechanism could be explained theoretically.

Carl G. Fälthammar, Alfvén's student and close associate mentioned that though it is not widely recognized that as early as 1937 Alfvén argued for the existence of a galactic magnetic field and by inference an ionized interstellar medium, both of which were at that time considered impossible but now, of course, are well established

As to the theory of the origin of the Universe, Alfvén had his favourite slogan: 'In the beginning there was plasma'. To understand the electricity and magnetism in space and the interaction of electromagnetic fields with conducting ionized matter in the plasma Universe was his passion which did not leave him till the very last days of his life.

Hannes Alfvén contributed towards the progress of space and astrophysical sciences not only through his work but by inspiring many students, colleagues and friends all over the world. I pay my homage to this great scientist and will miss his inspiring correspondence.

Professor S. N. Bose's contribution to quantum statistics – A critical review

S. K. Das and S. Sengupta

'The Indian Bose has given a beautiful derivation of Planck's law including the constant (i.e. $8\pi\nu^2/c^3$)', wrote Einstein in July 1924 in a letter to Ehrenfest. He further commented that 'Bose's derivation is elegant but the essence remains obscure'[1]. We see that Bose's work, from the very beginning, evoked a sense of mystery which haunted physicists even after a lapse of more than 50 years. The first surprise is that quantum statistics, the last major discovery in quantum theory prior to the advent of quantum mechanics, was initiated by a man almost unknown to the world of physics, living in isolation in Dacca (now in Bangladesh), far removed from the main centres of hectic activities in this field. It is doubtful if there is a second example like this in the history of physics. Perhaps it is this unbelievable element in Bose's discovery which prompted the Nobel laureate scientist Max Delbruck to ask 'Was the Bose–Einstein statistics arrived at by serendipity?'[2]. The same spirit is revealed in Pais' remark that 'Bose's work is the most successful shot in the dark'[3]. There is, however, a more important reason to suspect that the discovery might have been accidental. The first three papers on the subject published in quick succession (the first two papers of Bose[4,5] published in July 1924 and the first paper of Einstein[6] in September 1924) make no mention of the most significant step forward in quantum statistics, viz. the concept of indistinguishability of the particles. It is really surprising that neither Bose nor Einstein in their first paper considered it necessary to examine critically the derivation of the new expression for thermodynamic probability. It is only in his second paper[7] (published in December 1924) that Einstein discussed this problem in detail after Ehrenfest and others pointed out the gap.

In this connection we mention a few more interesting features not quite well known. Bose actually gave two different expressions for thermodynamic probability in his two papers. In the first paper[4] he writes

$$W_1^s = \frac{Z^s!}{p_0^s!\, p_1^s! \cdots} \quad W = \Pi_s W_1^s \qquad \text{(B1)}$$

where Z^s is the total number of elementary phase cells belonging to photons of energy $h\nu^s$, in which N^s photons are distributed. p_r^s is the number of cells which contain r photons. As a result we have

$$\sum_r p_r^s = Z^s \quad \text{and} \quad \sum_r r p_r^s = N^s.$$

In the second paper, Bose writes

$$W_2^s = \frac{(Z^s + N^s - 1)!}{N^s!\,(Z^s - 1)!} \approx \frac{(Z^s + N^s)!}{N^s!\, Z^s!}$$

and $W = \Pi_s W_2^s$. (B2)

Before giving the expression (B1), Bose simply writes 'now it is easy to calculate the thermodynamic probability (macroscopically defined) of a state'. He gave no idea as to how he arrived at the expression or why he chose the particular description of the macroscopic state. In the second paper, while discussing the thermodynamic probability for radiation, Bose writes that 'this has been derived earlier'. And he gives two references. One is a paper by Bose to be published in *Philosophical Magazine*, but actually it was never published. The other is a paper by Debye (the paper published in 1910, which we shall discuss later). Thus, we do not have any record of the details of Bose's derivation of either (B1) or (B2).

Mehra[8], while commenting on the relation between the two expressions, says that W_1^s can be reduced to W_2^s. This, however, is wrong. W_1^s summed over all possible distributions of p_r^s leads to W_2^s. Similar imprecise remarks have also been made by Ghose[9] while comparing (B1) with (B2). Einstein used (B1) in his first paper and derived (B2) using the concept of indistinguishability, in the second paper. Pais[10] remarked wrongly that (B2) is the 'Einstein's expression for W now used in textbooks'. It is generally believed that Bose derived the photon statistics by dropping the constraint on N, the total number of photons. He kept only E, the energy, as constant. This is not quite correct. Such confusions arise because the differences in Bose's two derivations have never been examined critically. In his first paper, it appears that Bose maximized $W = \Pi_s W_1^s$, but in fact he was maximizing W_1^s. Here he was maximizing with respect to variables p_r^s (which are regarded as the macroscopic parameters here) and it turns out that the procedure is equivalent to maximizing each W_1^s separately keeping Z^s and $E^s = N^s h\nu^s$ constant. This implies that the photon number N^s is also kept constant. Pais[11] comments that 'the final irony is that the constraint of fixed Z^s is irrelevant'. This is a careless remark. In the logarithmic derivative of W_1^s, one has to use this condition. However, the additional input of this condition through Lagrange's multiplier turns out to be trivial and unnecessary. But this is only an accidental result. In his second paper, Bose maximized W_2^s with respect to the variables N^s keeping only $E = \Sigma_s N^s h\nu^s$ constant. Many such misconceptions seem to arise because physicists, in general, completely overlook Bose's second paper.

A more significant misconception is that quantum statistics started with Bose's work. In his second paper, Bose starts with a critical examination of a paper by Debye[12] published in 1910, where he used statistical mechanics to derive Planck's law. Bose concludes that Debye's derivation is consistent with the photon description except for his derivation of the factor $8\pi\nu^2/c^3$. Debye used an expression for W^s first written down by Planck in his book *Warmestrahlung* (English translation[13] appeared in 1913). This expression is identical to (B2) but Z^s and N^s were given a slightly different meaning. Natanson[14], in 1911, derived Planck's law using an expression for W^s which is identical to (B1). Both Debye and Natanson described black-body radiation in terms of normal-mode vibrations. This is equivalent to the description of radiation as an ensemble of harmonic oscillators. In 1914, Ehrenfest and Kamerlingh Onnes[15] published a paper in which they tried to interpret Planck's formula (B2) in terms of the distribution of photons. They concluded that if photons are regarded as mutually independent, Planck's formula cannot be obtained. (See refs. 8 and 9 for a brief summary of these and other works.)

The influence of these earlier works in the development of quantum statistics has mostly been ignored. The central mystery that Bose discovered the photon statistics without discovering the basic concept of indistinguishability of photons remains unresolved. Authors reporting Bose's work fill up the gap by asserting that implicitly Bose introduced the concept of indistinguishability. Such statements are not true and do not put Bose's work in the right perspective.

We suggest an alternative angle to look at Bose's contribution. Based on available facts and some plausible conjectures, we show that Bose was partly right when he said that he was doing a Boltzmann type of calculation. In this work he was strongly influenced by earlier works, particularly Planck and Debye. Thus, a continuity in the development of quantum statistics can be established. This is possible because of a fortunate circumstance. The concept of indistinguishability can be pushed back till we come to discuss the Bose–Einstein statistics of classical particles. For photons this concept is not an essential requirement. For example, if one uses Gibbs canonical ensemble formalism, one can avoid the concept of indistinguishability.

There is another interesting aspect of Bose's work. A photon when regarded as a particle has an unusual nonclassical property. It has only one energy state of energy $h\nu$ and momentum $h\nu/c$. If we try to change the momentum, we have to change ν and this will give us a new photon and not an excited state of the earlier photon. Thus, for an ensemble of N identical photons of energy $h\nu$, if $E = Nh\nu$ is kept constant, N becomes a constant and no variation is possible. Photons with different frequencies are not indistinguishable. If we consider radiation in an enclosure to consist of different frequencies ν^s, then through absorption and re-emission by a speck of matter the number N^s of each type of photons can be changed and variation of the probability function W becomes possible. But such an ensemble consists both of distinguishable and indistinguishable photons. This naturally raises the question, what type of statistical ensemble of photons was considered by Bose? Can this ensemble be compared with the standard Boltzmann or Gibbs ensembles used for classical particles? We discuss this question later.

Bose's two expressions for W: A conjecture on how Bose arrived at them

The basic difference between the two expressions for W which Bose used is in the definition of the thermodynamic macrostate. In (B1) this is defined by the variables p_r^s and in (B2) by N^s. The necessity for this arises because the ensembles considered are really different, though apparently they seem to be the same. We shall take up this question later. At present we are interested in the mathematical relation between the two expressions. This relation is rather complex and many misstatements are found in the literature. Let us first write the correct relations:

$$W_2^s = \sum_{(\cdots p_r^s \cdots)} W_1^s \quad . \qquad \text{(R1)}$$

Here s is kept fixed and the summation on the right-hand side is over all possible sets of distributions defined by $(\cdots p_r^s \cdots)$ keeping N^s and Z^s fixed. It is evident that $\Pi_s W_1^s \neq \Pi_s W_2^s$ for arbitrary distributions. Let us now suppose that we allow permutations among the photons, regarding them as classical particles. Then we get

$$\sum_{(\cdots p_r^s \cdots)} W_1^s \times \frac{N^s!}{\Pi_r (r!)^{p_r^s}} = (Z^s)^{N^s}. \qquad \text{(R2)}$$

The right-hand side gives the well-known classical value. The correctness of these relations can be checked only by showing that they treat the same combinatorial problem using different procedures. As we see, the relations are far more complex to be comprehended intuitively. It is a good and worthwhile exercise to take up a special case with small values of Z^s and N^s and verify the relations.

In the Planck–Debye derivations of (B2), there is a change of language. They consider radiation as an ensemble of quantized harmonic oscillators. Z^s is interpreted as the number of oscillators of frequency between ν^s and $\nu^s + d\nu^s$. Excitation energy of an oscillator is written as $(n^s + \frac{1}{2})h\nu^s$ and, of all the oscillators in Z^s, $\Sigma n^s h\nu^s$ + constant is the zero-point energy. Dropping the constant part, the total excitation energy of the oscillators is $E^s = N^s h\nu^s$, where $N^s = \Sigma n^s \cdot N^s$ may be defined as the total excitation number for the Z^s oscillators. The difference in the interpretations of the two quantities Z^s and N^s by Bose and Planck–Debye is very significant (Table 1).

It is to be noted that the mathematical expressions for Z^s and E^s are the same in the two interpretations. If we look at the combinatorial problem of distributing the number N^s in Z^s oscillators (Planck–Debye picture) then the result is the same as in (B2). Here Z^s-oscillators are all distinguishable and the question of identity of photons does not arise. Hence, the calculation follows a straightforward Boltzmann method. When we try to evaluate W^s using the Bose picture, two different results are obtained. If we drop permutation among photons, we get (B2). But if we allow permutation, we get $W^s = (Z^s)^{N^s}$. The central problem is that Bose, who was well conversant with Boltzmann's method of calculation, should have written down this expression. Instead he wrote (B2). Why?

In his statement to Mehra[16], Bose stated that he had read Planck's book *Warmestrahlung*. In his second paper[5] Bose examined Debye's paper critically. It is clear that he was familiar with the expression (B2) for W^s. 'Debye has shown that Planck's law can be derived using statistical mechanics', with these words Bose starts his second paper. But Bose

Table 1. Difference in the interpretations of Bose and Planck–Debye

	Bose	Planck–Debye
$Z^s = 8\pi\nu^{s^2} d\nu^s v/h^3$	Number of elementary phase cells, each of volume h^3, belonging to photons of frequency lying in the range ν^s to $\nu^s + d\nu^s$	Number of different harmonic oscillators belonging to the frequency range ν^s to $\nu^s + d\nu^s$
N^s	Total number of photons in Z^s cells	Total excitation number of the Z^s oscillators
$E^s = N^s h\nu^s$	Total energy of all the photons in Z^s	Total energy of all the oscillators in Z^s

objects that his derivation is not completely independent of classical electrodynamics. Because Debye calculates the number Z^s by using the idea of normal-mode vibrations, i.e. using the idea that radiation has a wave nature. Bose strongly believed in Einstein's photon picture of radiation. His one obsession was that if this idea is correct then one must be able to derive Planck's law by considering radiation as an ensemble of particles (photons) and in no way using the wave picture. Debye's use of normal modes in deriving Z^s was considered by Bose as a serious flaw in this scheme. So he replaced this by a new derivation by introducing the concept of phase space of photons each of which has a momentum $h\nu^s/c$. In this new picture Bose writes '$8\pi\nu^2\, d\nu\, v/c^3$ can be interpreted as the number of elementary cells in the six-dimensional phase space of the quanta. *Further calculations (of Debye) remain essentially unchanged*'. The last comment has a crucial significance. It means that Bose assumes that in the photon picture, Debye's calculation of W^s (i.e. (B2)) remains unchanged. By implication it follows that Debye's idea of an oscillator excited to a state of energy $n^s h\nu^s$ is, in Bose's language, equivalent to having n^s phonons each of energy $h\nu^s$. This equivalence is basically right as has been proved after quantization of radiation field. But in 1924 it was not known. Here Bose showed superb intuition. With this equivalence, both the expressions for Z^s and E^s become identical in the two pictures of radiation (ensemble of photons and ensemble of normal-mode vibrations). Hence, if Planck's law is to be derived, the expression for W^s must necessarily be the same in the two pictures. Our conjecture, based on the brief statements of Bose quoted above, is that Bose arrived at this conclusion through intuition and did not wait for a proper analysis of the implications. This conjecture alone can explain the way he introduced the expression for W^s for photons in his second paper – 'Thermodynamic probability for radiation: This has been derived earlier[7]'. Reference 7, as we have mentioned earlier, contains Debye's paper. Our conjecture also explains why Bose thought that he was not introducing any basically new concept in the calculation of W^s. Once the equivalence is taken for granted, one can utilize the Planck–Debye derivation of W^s, which is done entirely in the Boltzmann framework.

What about Bose's formula for W^s in the first paper? We do not know if Bose had seen Natanson's paper of 1911, where the expression (B1) was derived using the Planck–Debye picture. Naturally, here our conjecture will be more speculative. Our guess is that Bose was not aware of Natanson's paper. Otherwise, he would have referred to it as he had referred to Debye in his second paper. Planck, in his book, considered radiation of a single frequency. His ensemble consisted of N^s quantum oscillators all of frequency ν^s. For this he derived the expression for W^s (i.e. (B2)). But here both the parameters Z^s and N^s are constant and there is no variable parameter with respect to which one can maximize W^s. Both Natanson and Bose independently resolved this difficulty by introducing the variable p_r^s. Bose, using photon language, had the additional constraint to make his expression for W_1^s consistent with the Planck's expression for W_2^s.

After enunciating the combinatorial problem as Bose had done in the first paper, one would immediately write down the expression for W_1^s. The question of permutation of the particles would come later. Our conjecture is that after writing W_1^s, Bose could easily check that it was consistent with W_2^s. So he was sure that the formula was correct, and he overlooked the finer details about the permutation of the particles. One thing seems almost sure, that Bose was not aware of the paper by Ehrenfest and Kamerling Onnes[15]. Had he seen this paper, it seems almost certain that the question of indistinguishability would have taken a prominent part in his paper.

The scenario changed completely when Einstein extended Bose's formula to classical particles. The alternative Planck–Debye picture is no longer valid and one has to justify the derivation of W_1^s or W_2^s independently. Hence, the concept of indistinguishability becomes essential.

Let us now summarize our conclusions. Firstly, Bose reinterpreted the Planck–Debye derivation of radiation formula in terms of photon language. In doing this he correctly anticipated that both the languages are true and that the expression for W^s remains unchanged by the change of language. This equivalence made it possible for Bose to derive photon statistics without introducing the concept of indistinguishability. Secondly, Bose introduced the concept of phase space of photons, which made his photon statistics look almost identical to particle statistics. This led to the extension of his formula for W^s to classical particles. In the Planck–Debye language one could not even think of such an extension.

Statistical ensemble in Bose's two derivations

We have already mentioned some very peculiar nonclassical properties of photons. As a result, an ensemble of photons will have properties not exactly similar to those of an ensemble of classical particles. Hence, it is relevant to discuss precisely what sort of ensembles Bose used in his photon statistics.

In the first paper Bose writes $S = k \ln W$, $W = \Pi_s W^s$ (W^s given by (B1)). The constraints are $Z^s = \Sigma_r p_r^s$, $E = \Sigma_s \Sigma_r h\nu^s r p_r^s$. Apparently, it may seem that Bose is considering an ensemble of photons of all frequencies and maximizing W. But, in fact, he was maximizing only W^s keeping Z^s and $E_s = N^s h\nu^s$ constant. It is easy to see that, if we do this, all of Bose's results remain the same. This is because each ensemble of N^s photons has a most probable distribution for p_r^s corresponding to the equilibrium state at a temperature T, say. If all these ensembles are put in thermal contract, they will still be in equilibrium. Thus, maximizing W^s in terms of p_r^s automatically maximizes W.

Thus, Bose, in the first place, was considering a Boltzmann ensemble of N^s identical photons each of one energy stage $h\nu^s$. The nonclassical feature of this ensemble is that when E^s is kept fixed, no variation of W^s is possible. The situation is somewhat like an ensemble of particles all of whose energy states are degenerate. Bose introduced a new definition of a macroscopic state in terms of the parameters p_r^s, which can then be varied to give different values of W^s. It is interesting to note that in terms of the Planck–Debye picture, variables p_r^s come out quite naturally. The ensemble of Z^s oscillators with a total excitation energy $E^s = N^s h\nu^s$ is a simple Boltzmann ensemble, where the distribution parameter is the number of oscillators excited to the rth state of energy $rh\nu^s$, and this exactly corresponds to the variable p_r^s

defined by Bose. This again confirms our conjecture that Bose was intuitively convinced about the mathematical identity of the two descriptions of radiation.

In the second paper, Bose, following Debye, maximizes W and not W^s. Here the distribution parameter is N^s. The ensemble is neither Gibbs canonical nor Boltzmannian. It is semi-Gibbsian. We have N^s identical photons as a subensemble. Varying ν^s, we generate other subensembles and put them in thermal contact. Photons in any two subensembles are nonidentical. Since W^s depends on Z^s and N^s, we can change W^s by varying N^s and then maximize W by the usual technique. The only constraint here is that $E = \Sigma_s N^s h\nu^s$, a constant.

Summary

Bose had been plagued throughout his life by the question how he got the formula for W^s without using the indistinguishability concept. In an interview with Mehra[17] towards the end of his life, he stated: 'I had no idea that what I had done was really novel . . . Instead of thinking of the light quantum just as particles, I talked about these states. Somehow, this was the same question which Einstein asked when I met him (in October or November 1925), how had I arrived at this method of deriving Planck's formula.' Bose thought that he was using the standard Boltzmann method. And we believe that he was right.

The development of quantum statistics is not as abrupt as is usually believed. There is a continuity starting from the works of Planck, Debye, Natanson, Ehrenfest and Kamerling Onnes and others. This has been possible because, for radiation, there are two alternative ways of treatment; one may consider it as an ensemble of distinguishable quantized harmonic oscillators (Planck–Debye picture) or as an ensemble of indistinguishable photons (Bose picture). Both lead to the same expression for W. Bose used the photon language to describe the ensemble but the Planck–Debye picture to calculate W and thereby sidetracked the question of indistinguishability. When Einstein extended Bose's expression for W to particles, then the alternative Boltzmann picture of oscillators disappeared. One can derive the particular expression for W by using the concept of indistinguishability alone. And this Einstein did in his second paper.

In the history of physics, the discovery of the B–E statistics is a remarkable example to show how tortuous the path along which ideas in physics develop is. We are reminded of the incisive remark by Koestler[18], made in connection with the discoveries in cosmology: 'The history of cosmic theories may without exaggeration be called a history of collective obsessions and controlled schizophrenia; and the manner in which some of the most important individual discoveries were arrived at reminds one more of a sleep-walker's performance than an electronic brain's.'

MEETINGS/SYMPOSIA/SEMINARS

32nd Annual Convention of Indian Geophysical Union and Meeting on Marine Geophysics

Place: National Geophysical Research Institute, Hyderabad
Date: 19–21 December 1995

Topics include: 1. Geophysical instrumentation. 2. Atmospheric sciences. 3. Geophysical exploration. 4. Space sciences and planetology. 5. Geodynamics. 6. Lithospheric studies. 7. Marine geosciences.

Contact: Dr P. R. Reddy
Hon. Secretary, Indian Geophysical Union
NGRI Campus, Hyderabad 500 007
Phone: 670141

International Symposium on Geology and Geophysics of the Indian Ocean

Place: National Institute of Oceanography, Goa, India
Date: 21–24 October 1996

Topics: 1. Structure and tectonics. 2. Particle fluxes and sedimentary processes. 3. Sea-level changes and paleoceanography. 4. Non-living resources of continental margins. 5. Deep-sea mineral deposits and their environment. 6. Technology, policy, economics and geopolitics of offshore exploration and exploitation

Contact: Dr Ch. M. Rao, Convener
National Institute of Oceanography
Dona Paula, Goa 403 004, India
Phone: 91-(0)832-221352
Fax: 91-(0)832-223340/91-(0)832-221360 (BTIS)
e.mail: ocean@bcgoa.ernet.in

4th International Conference on Physiological Fluid Dynamics

Place: Jiwaji University, Gwalior, India
Date: 8–10 December 1995

Topics include: Biorheology, Atherosclerosis, Flow visualization, Clinical hemorheology, Simulation/modelling, Biotransport, Microcirculation, Arterial hemodynamics, Red cell deformability and aggregation.

Contact: Prof. V. P. Saxena, Secretary
School of Mathematics & Allied Sciences
Jiwaji University, Gwalior 474 011, India
Phone: (0091) (751) 341905
Fax: (0091) (751) 341450

Indian Association of Special Libraries & Information Centres (IASLIC) XX All India Conference on Information Technology Products of 1990s and Library and Information Centres

Place: Dept. of Library & Information Science
Lucknow University, Lucknow, U.P.
Date: 26–29 December 1995

Topics include: Information technology as media, Computer software information products, Information seeking behaviour and information technology products, Infrastructural facilities needed for utilisation and maintenance of information products, Economic feasibility studies of information technology products, Legal implication to utilisation of information technology products, Competency in utilisation of information technology products knowledge and skills.

Contact: Convener
Editorial Committee
XX All India Conference
IASLIC, P-291 CIT Scheme 6M, Kankurgachi
Calcutta 700 054
Phone: 349651

National Symposium on Recent Advances in Biosciences

Place: Dept. of Biosciences, Maharshi Dayanand University, Rohtak
Date: 14–16 October 1995

Contact: Prof. V. P. Agrawal
Secretary General
Society of Biosciences, 25/4, Ram Bagh Road
Musaffarnagar 251 001, U.P.

National Symposium on Deccan Flood Basalts of India

Place: Nagpur
Date: February 1996

Topics include: 1. Stratigraphy, structure and tectonics. Geophysical studies leading to understanding of sub-Deccan crust and mantle. 2. Geological and volcanological studies. Morphological characters of lava flows and interpretation of volcanic history. 3. Petromineralogical, geochemical and petrogenetic studies. 4. Genesis and evolution of magma, composition of sub-continental mantle, degree of crustal contamination and genesis of small volumes of magmas of extreme compositions. 5. Age and duration, palaeomagnetism, palaeontological studies on infra and intertrappean beds. 6. Geomorphology, plateau uplift and erosion, recognition and dating of planation surfaces. 7. Intrusives: Geology, geochemistry, structure and tectonics, age, palaeomagnetic characters, spatial and temporal relationship between intrusives following different tectonic trends and of differing compositions, recognition of feeder dykes. 8. Geophysical, geotechnical and seismic studies. 9. Economic aspects, including groundwater potential, with special emphasis on geothermal energy resources and prospects for polished stone industry.

INFORMATION FOR CONTRIBUTORS

GENERAL

All manuscripts should be addressed to the Editor, *Current Science*, P. B. No. 8001, C. V. Raman Avenue, Bangalore 560 080. Submission of an article will be held to imply that it has not been previously published and is not under consideration for publication elsewhere; and further, that if accepted, it will not be published elsewhere. *Three copies of contributions of all categories* are required, with a letter of transmittal giving (i) names and complete addresses of the authors and (ii) title of the contribution and the category in which it is submitted (see below).

Current Science is a multidisciplinary journal and therefore research and review papers of general significance that are written clearly and well organized will be given preference. All papers will be first assessed by a Reviewing Editor. Papers found unsuitable in terms of the overall requirements of the journal will be returned to the authors. The others will be sent for detailed review. *Both solicited and unsolicited material will be reviewed.* Authors of these papers will be notified of acceptance, rejection, or need for revision of the paper. Returned papers cannot be resubmitted.

Illustrations and other material to be reproduced from other publications must be properly credited; it is the authors' responsibility to obtain permission for reproduction (copies of letters of permission should be sent).

CATEGORIES OF MANUSCRIPT

General articles (not exceeding 5000 words) discuss current trends in research in a field that will be of interest to readers outside the field; interdisciplinary topics: science policy and administration; or some aspect of the application of science and technology to human needs or the impact of science and technology on society/ecosystems/life. They should include a summary not exceeding 100 words, introductory paragraph(s), brief subheads at appropriate places to point to what follows, illustrations that will help a general reader, and references.

Review articles (not exceeding 5000 words) are expected to survey and discuss recent developments in a field. They should be well focused and organized, and avoid a general, 'textbook' style.

Research articles (not exceeding 4000 words) should report research results of fairly major significance. They should include an abstract not exceeding 100 words, introductory paragraph(s), and brief subheads.

Research communications (not exceeding 2000 words) should contain important findings that are novel and of fairly broad interest. They should include a brief abstract and an introductory paragraph. Text should not be broken up under subheads.

Correspondence includes letters, not exceeding 500 words, that are of general interest to scientists. All letters cannot be published.

Scientific correspondence contains technical comments, including those on articles or communications published in *Current Science* within the previous six months. Letters may be reviewed and edited.

Research news articles are intended to inform nonspecialists about recently published advances or important findings discussed at a meeting. Authors should also send a copy of the paper(s) on which the article is based. Meeting reports should avoid merely listing brief accounts of topics discussed, and must convey to readers the significance of an important advance.

Research accounts articles are intended to be personalized reviews of research from the authors' own laboratory, based on a body of published work. The articles must provide appropriate background to the area in a concise introduction, which should also serve to place the author's work in proper perspective. Articles will normally not exceed 8 to 10 printed pages.

Opinion articles present views on issues related to science and scientific activity. **Commentary** articles should contain expository notes on issues related to science and scientific activity.

Book reviews. Unsolicited reviews will also be considered. Reviews that merely 'list' brief descriptions of the contents cannot be published. Reviews should have 'context' and convey some information about the subject of the book.

Historical commentary and notes inform readers about interesting aspects of personalities or institutions of science or about watershed events in the history/development of science; most are expected to relate to India. Illustrations are welcome. Brief items will also be considered.

MANUSCRIPT PREPARATION

Manuscripts should be typed double-spaced on one side of white bond paper (21 × 28 cm). The pages should be numbered consecutively, starting with the title page and through the text, reference list, tables and figure legends. The **title** should be brief, specific and amenable to indexing. Not more than five **keywords** should be indicated separately; these should be chosen carefully and must not be phrases of several words. **Summary** and **abstract** should not have more than 100 words and should convey the main point of the paper, outline the results and conclusions, and explain the significance of the results.

Text. All papers should have a brief introduction. The text should be intelligible to readers in different disciplines and technical terms should be defined. Tables and figures should be referred to in numerical order. All **symbols** and **abbreviations** must be defined, and used only when absolutely necessary. Superscripts and subscripts and ambiguous characters should be clearly indicated. **Units of measure** should be metric or, preferably, SI. Methods should, as far as possible, be described briefly in appropriate table and figure legends.

Figures. In the case of line drawings one set of originals (without any lettering) is sufficient, with two copies containing lettering. In the case of photographs good prints are required with each copy of the manuscript; photocopies are not acceptable. Line drawings should be roughly twice the final printed size. The correct orientation should be indicated if not clear.

Photomicrographs and other photographs that require it must have a scale bar, which should be defined clearly in the legend. Primary data should be submitted as far as possible (e.g. actual photographs of electrophoretic gels rather than idealized diagrams).

References should be numbered in the order in which they appear, first through the text and then through table and figure legends. The following are examples of ways of writing references.

1. Mukundan, T. and Kishore, K., *Curr. Sci.*, 1991, **60**, 355–362.
2. Constantine, G., in *Biology of Bats* (ed. Wimsatt, W. A.), Academic Press, New York, 1970, vol. 1, pp. 319–322.

Acknowledgements should be brief. Footnotes are not allowed except to identify the corresponding author if not the first.

Cover photographs. Good photographs (colour or black and white) that pertain to a submitted paper will be considered for use on the cover. Good *prints* and a legend should be submitted with the manuscript. In the case of a colour picture, a transparency will be required for printing if accepted.

PROOFS AND PUBLICATION

Two sets of galley proofs are sent to the corresponding author. A reprint order form accompanies the proofs.

High seismic hazard along the central Himalaya (Dehra Dun to Muzaffarpur), and risk to Tehri dam

The first step in estimating earthquake hazard in an area, from which engineering specifications could be derived for the design of earthquake-resistant structures, is to define the possible earthquake threat(s) to the region. This, in turn, requires (a) delineation of the most likely fracture plane(s) (geological faults) that could be the site where long-accumulated strain will be suddenly released and (b) rates of strain accumulation and the current strain budget(s) of these faults or fault systems, the last of these being difficult to determine directly except through stress measurements and/or the historical records of past earthquakes associated with the fault(s). Assuming a failure strain of 10^{-4}, one can then estimate the probabilities of exceedance of strain release or slip on these faults over a given period of time in the future, and further, as shown by Khattri (**page 161**) the expected ground motion time histories and the probabilities of exceedance of ground motion parameters (displacement, velocity, acceleration and duration of strong shaking) at a specified distance from them. The latter constitute the basic quantities needed for a seismic design.

Earthquake hazard in the Himalaya and in the adjoining densely populated plains to the south is dominated by the great plate boundary earthquakes which accompany a sudden slip of the persistently northward driving Indian plate, beneath the overriding Himalaya. Once every few hundred years, therefore, when the steadily accumulating strains exceed the bearing capacity of the intervening fault systems, various segments of the Himalaya lurch forward over the foothill plains in a giant leap of 6–10 m along a gently northward dipping fracture plane, which is typically 300 km long and 100 km wide.

However, the entire 2400 km long Himalayan belt from Nangaparbat in the west to Namcha Barwa in the east, although compressed at approximately the same rate, does not slip as a single continuous rupture. For, there are a number of transverse fractures incised by the strong preexisting grains of the underthrusting Indian plate, that segment the Himalayan arc mechanically, thereby providing an additional degree of freedom which allows its various segments to slip independently, adjusting the times of their slippage (earthquakes) according to the nature and strength of their respective fault asperities. Thus, the giant slips of the various Himalayan segments whilst having approximately equal renewal intervals (recurrence periods of great earthquakes) tend to stagger in time.

Four great earthquakes have been known to rupture about half of the Himalayan plate boundary over the past 100 years, and although a direct determination of the strain rate across this boundary still remains to be made, various constraints indirectly indicate a figure of 15 mm/yr (strain rate $\approx 1.5 \times 10^{-7}$/yr). This, in turn, suggests that the recurrence interval for a great Himalayan earthquake would be about 600 years. Unfortunately, our historical record of seismicity in India is rather poor, which makes it impossible to estimate the current strain budget along a fault that has no known record of an associated earthquake in the past, even if the rate of strain accumulation is known.

It will thus be apparent that whilst it would be safe to assume that those parts of the Himalaya which have ruptured in the past 100 years are unlikely to accumulate enough strain for a great earthquake at least for the next 400–500 years, others that have not been ruptured for 500–600 years by a great earthquake have most likely accumulated more than 8 m of slip (strain $\approx 10^{-4}$) and are, therefore, ripe for a great earthquake which could have a magnitude greater than 8.5.

One such long segment in the Himalaya where no great earthquake has occurred since the 13th century and where potential seismicity is, therefore, extremely high is the Central Himalayan seismic gap extending from Dehra Dun to Muzaffarpur. Since a number of large dams are being constructed in this area, an evaluation of its seismic potential over the next 300–400 years, covering the life and residual after-effects of the dam, has been a matter of great public concern and regrettably of an unresolved public debate between seismologists and engineers, particularly in respect of low estimates of earthquake hazard and high percentile of risk adopted in the engineering design of the dam structure.

Two well researched papers in this issue (Bilham, **page 101**) and (Khattri, **page 161**) address the two main arguments underlying the adoption of low hazard figures: (a) the assumption that the 1833 Nepal earthquake did considerably diminish the accumulated strain in this part of the Himalaya and (b) that the rock attenuation figures in the area being high, ground accelerations would decrease rapidly away from the fault. The two papers contained in this issue provide enough evidence to refute both these possibilities, and call for attention to the dangerous consequences of inadequate safety figures incorporated in the design of this large critical structure.

The first paper by Bilham shows convincingly that the only major earthquake to occur in this region after the well-documented disastrous earthquake of 1255 was the 1833

Nepal earthquake, which more or less coincided with the western extremity of the 1934 Bihar earthquake rupture and, in any case, was too moderate to cause any significant reduction of the strain budget in the Central Himalayan seismic gap. The message, therefore, is that this sector of the Himalaya has not experienced a great earthquake for about 750 years and unless accumulating strains are relieved by aseismic creep, which appears unlikely on the basis of the evidence of recent levelling data in Nepal, the accumulated slip in the region may be as high as 10 m, capable of generating a great earthquake of magnitude 8.5–9.0 in the near future.

The second paper by Khattri, using the actual ground acceleration records of the 1991 Uttarkashi earthquake as a basis for simulating the ground acceleration record at Tehri, which lies in the Central Himalayan seismic gap, shows that peak ground acceleration expected to occur at Tehri in the wake of $M = 8.5$ earthquake would be as high as 1.0 g, and would continue to shake the ground intensely a period longer than 20 s.

These two papers thus make a valuable and timely contribution towards alerting all those concerned with the construction of large critical facilities in the Central Himalaya to study carefully the scientific results and computer-simulated visualizations that argue against the unrealistically low figure of earthquake hazard adopted in the design of the 260 m high Tehri dam and to revise its design so as to ensure long-term protection to large unwary communities downstream.

Molecular processes: Faster and faster

Chemical kinetics is the study of the rates of chemical reactions and their interpretation in terms of molecular mechanisms. Classically, the determination of rates was restricted to processes occurring in time scales of several seconds or longer due to limitations of measurement. Over the last forty years or so there has been a steady improvement in the shutter speed of chemists' cameras. While measurements in the millisecond regime were at the forefront in the 1950s, even picosecond time scales will be passé in the late 1990s. Technical barriers have been regularly breached and experimental studies of femtosecond (10^{-15} s) processes are now possible.

Part of the motivation for studying ultrafast molecular processes stems from the increasing inroads that have been made in understanding critical biological events in ultimate chemical detail. Electron transfer processes in photosynthesis and the critical isomerization of the visual pigment retinal in the rhodopsins following photoexcitation are among the best studied. It is after all enormously exciting to be able to follow events immediately after photon capture which eventually lead to the wonderful phenomenon of vision. Biology affords the physical scientist an extraordinary range of immensely complex problems, which may be addressed using techniques that have been tried and tested on the more tractable problems of physical chemistry.

Ions and molecules in solution are solvated and there is an unceasing dance of chemical species in solution, modulated by myriad interactions. Excitation of chromophores most often leads to changes in charge distribution, necessitating solvent rearrangements to achieve an equilibrium excited state. Measurements of solvent reorganization times, sometimes of the order of 200 fs to 1 ps, have become possible recently using ultrashort laser pulses, providing remarkable temporal resolution of molecular processes. The detection of ultrafast events in liquids like water, methanol and acetonitrile, of course, raises the question of their origin. This is happy hunting ground for theoreticians and provides many insights into the dynamic behaviour of liquids.

For the connoisseur of ultrafast events, electron transfer is undoubtedly one of the most delectable items on the menu of chemical processes. The celebrated Marcus theory is the cornerstone in the understanding of electron transfer. Can solvents or the medium affect the very rapid electron transfer reaction? Recent studies suggest that there are specific situations where medium effects are indeed observable. What appears to be a rather esoteric area of physical chemistry may acquire broad importance in the light of the determination of the detailed molecular structures of proteins involved in biological electron transfer, where electrons hop between metal ion centres through a dense thicket of protein atoms, with the aqueous solvent being almost completely excluded. The interplay of experiment and theory has been particularly fruitful in the area of ultrafast chemistry as highlighted in the review by Bagchi (**page 129**).

CORRESPONDENCE

Patenting biotechnologies

The National Institutes of Health (NIH), Bethesda, is seldom away from controversies where patents are involved. Perhaps, as a major sponsor of biological research, it stands to gain more than any other corporate body in the USA. Bernadine Healey, the former Director of NIH, first pushed for patenting of random human gene stretches. These were dropped in a hurry when the scientific community protested. Even Medical Research Council of UK after beginning like NIH soon backtracked. Last month, however, NIH volunteered back into the hotseat. And this time, it is for patenting the basic technique of *ex vivo* gene therapy! The application made in 1989 had initially sought protection for all techniques of gene therapy, both *in vivo* and *ex vivo*. The claims were watered down by the US patent office and now the patent covers only those *ex vivo* manipulations in which malfunctioning human cells are genetically altered to produce therapeutic levels of protein outside the body and then replaced. Fortunately, this patent does not cover 'alternative techniques' and is restricted to the United States. Even then, the cover is big enough to alarm researchers. Normally, this would not hamper research. Yet anyone wanting to commercialize any form of gene therapy may have to get a sublicence to do so. With many players in the game, it does not appear likely that the patent will go unchallenged. There has been of late some interest in gene therapy in India, and the US experience is a pointer for Indian professionals engaged in biotechnology.

What we Indians should especially take note of is the receptivity of the US patent office to changing technological and commercial scenario. The move by the US PTO underlines its realization that gene therapy is likely to succeed as a viable therapeutic technology in the coming years. The departure from its previous stance of insisting on extensive proof of the utility of the invention before granting a patent only strengthens this observation.

The Indian patent system, in comparison, has twisted itself into knots making compromises. Notwithstanding the failure of the bill in the Rajya Sabha and its dubious fate, the Ordinance does not have any teeth for biotechnology inventions. The current stance of the Patent Office to turn down anything genetic or involving DNA ('Agracetus syndrome') will do more harm than good to Indian science. There are several patentable inventions in the country's many laboratories that are not being patented abroad because of financial constraints, nor can they be patented in India because of the stance of the Indian patent office.

What laws apply to biotechnology patents in India? The Indian Patents Act of 1970 states that novelty, utility and a manner of manufacturing are the prerequisites to patenting. When a tangible substance or product results, the process can be patented [see 2(1)(J)]. Unfortunately, the Patent Office does not recognize methods of diagnosis, recombinant organisms, etc., as a substance or a tangible end-product. Read together with section 3(i), which states that 'any process for medicinal, surgical, curative, prophylactic or other treatment of human beings or any process for a similar treatment of animals or plants to render them free of disease or to increase their economic value or that of their products', the scope of obtaining a patent on biotechnological inventions in India is highly restricted. A crucial issue we have not addressed so far is defining microbial organisms in the legal context. Patents on recombinant organisms, elsewhere, are adjudged by the amount of human ingenuity involved and this calls for a legally defined reference point. Unlike other advanced countries, we have not made any distinctions between microbes and higher forms of life. Consequently, microbes are treated at par with animals and plants, and any method of modifying them contravenes the directives implicit in section 3(i) and therefore is not patentable. DNA probes, cloned and genetically engineered organisms are thus not patentable in India. Any biotechnological process done *in vivo* (even in a microorganism) does not lead to a new 'substance' while also enhancing its economic value, thereby rendering the invention nonpatentable under the 1970 Act! For food and drugs, effective protection will still be 5 years, a disincentive when one realizes that drug development may take at least as long, if not more.

There is no concordance amongst the various patent offices of the country in their interpretation of inventions pertaining to biotechnology. There are instances where applications disallowed by one office have been admitted in another. To compound to that, it is understood that an internal communique from the Controller General forbidding patent protection for certain biotechnological inventions, assigning no grounds for such a stand, has befuddled patent attorneys. This obviously has no legal sanction under the Act, yet it is another potential obstacle for the patent seeker, who then has to resort to legal recourse.

Filing applications under the World Trade Organization (WTO) has been seen as an alternative. Product patent can no doubt be sought under the WTO, yet biotechnological issues are, in effect, sidestepped. The ordinance does away with Section 39*, which made it mandatory for an Indian inventor to first seek an Indian patent before applying anywhere in the world! Under the new regime, an identical application must first be accepted in a convention country after 1 January 1995 against which the inventor can seek exclusive marketing rights in India. If the invention was made in India, and a process patent for producing that particular 'substance' had been granted, with the approval of the Controller, the inventor can enjoy exclusive marketing rights for five years or till a patent is granted or the application rejected. In all other cases, the Controller would not be calling for a patent examiner's report till 31 December 2004. Thus, even filing under the WTO in India means a long cold storage, a not too satisfactory proposition when one knows the short life-span of biotechnology products. Though product patents can be obtained for drugs, medicines and agrochemicals, the amendment does not affect the existing restrictions on the grant of patent protection in respect of *substances produced by chemical reaction*, alloys, optical glass, semiconductors and intermetallic compounds.

Indian inventors seeking patents abroad are very often stymied by the substantive examination of the US PTO. In determining prior art, the US PTO scans the available literature, which is apparently disjointed with no obvious interconnections, and then mosaics them, to state that from the emerging cited literature the idea is a logical extension and, therefore, obvious. The other stumbling block is the protection of patents and their 'alternatives'. Any substance substantively made by a similar process having substantively similar properties and giving substantively similar results is deemed as an 'alternative'. The cost of clarifying and/or modifying claims in response to the examiner's report is also too costly to discourage further action.

There are several Indian laboratories doing good work with genetic probes. Since patenting gene sequences is not allowed and any diagnostic process is deemed unpatentable, many Indian researchers are losing out in the international race.

The new use of a known drug has again become patentable in the US. With the expertise available in the West to isolate, characterize and synthesize plant alkaloids and other natural products with therapeutic properties faster, there is a potential threat that soon our wisdom of traditional medicine will be rendered impotent.

So what corrective measures do we take? Primarily, the ambiguity of the new Act must be resolved. Scientists and legislators should come together to propose distinctions between microbial entities and higher life forms on a legal perspective. The cost of patenting abroad is discouragingly exorbitant. Having gone for patent harmonization, would it not be logical to offer Indian scientists a levelled playing field to commercialize their inventions? Can we not make it possible for them to patent their inventions in India speedily so as to obtain a priority date to beat their competitors? It is not enough that we impel our scientists to patent. It remains with our planners to make the patenting environment conducive. We tend to make our laws not by anticipating trends but by following footsteps, even when they do not lead in our direction. It is time that our law makers took cognizance of Indian research capabilities in the biotechnology, pharmaceuticals and agrochemical sectors and legislate to favour them in the troubled years of international competition. We have been for far too long, as a nation, walking forward with our eyes over our shoulders!

*Section 39 is back, with the lapse of the Presidential Ordinance.

Why not platinum?

This note is intended to draw the attention of geoscientists to the need of looking at the platinum content of continental sulphide deposits.

The discovery of attractive quantities of gold and silver in oceanic sulphide deposits prompted a renewed interest in the continental sulphide deposits. Several important and interesting papers on this aspect were presented during the Annual General Meeting of the Geological Society of India in December 1994. Surprisingly, none dealt with the platinum content. In fact, one of the first publications on ocean floor massive sulphide deposits by Hekinian *et al.*[1] did report on the platinum content of the East Pacific Rise (21°N) deposits. Electron microprobe analysis revealed that platinum is present as a dispersed constituent in most sulphide phases that contain gold and silver. Its concentration ranges between 0.1 and 1.4% by weight. Further details of platinum in different sulphide phases can be found in Hekinian *et al.*[1].

Studies of oceanic sulphide deposits have been important in providing insights into the genesis of continental sulphide deposits which themselves formed in an oceanic setting once upon a time. So, when oceanic sulphides contain attractive quantities of platinum, why not look at the platinum content of continental sulphides, in addition to gold and silver?

If good amounts of platinum are indeed present in land deposits, it can change the scenario tremendously. One may also wish to have a fresh look at the platinum content of tailings from different sulphide deposits in the country.

The Academy document: A perceptive appraisal of science education in India

This is in response to the article entitled 'University education in Science' published in *Current Science* (10 February 1995), which emphasizes the need of an effective national policy on science education and research. The Academy paper is timely specially, because, of late, there has been considerable debate on the proposal made by a nonresident scientist, S. Mahajan, to set up a National Science University (NSU) in Delhi. The proposals included in the Academy document, unlike those in NSU, appear to be realistic, goal-oriented and remedial as regards attempts towards improving the overall status of science education and research in India.

The second part of the report that documents Academy initiatives is laudable and unique. The recommendations made under subheads such as 'efforts by the Academy through the fellowship', 'interaction with student and teacher communities', 'link with teaching departments and institutions' and 'contact with national bodies, agencies, etc.', if implemented properly would indeed elevate the level of education in science. However, I am of the view that the panel while making recommendations has avoided important issues that may have a bearing on the successful implementation of the Academy proposals.

The panel which has prepared the draft is surprisingly silent on the issue of what the medium of instruction in science education should be. In some part of our country science teaching at undergraduate (UG) as well as at postgraduate (PG) level is conducted in the vernacular. For example, at PG level in biology, when a teacher starts talking about the pituitary gland in a classroom, one should not be surprised if he finds a couple of blank faces staring innocently expecting to know the meaning of the pituitary gland; or in a physiology class a student might gather enough courage to ask, 'Sir, can you explain what do you mean by kidney?'. I am sure none of the Academy panelists has ever faced such a situation in a PG lecture room. Only a single line '... production of science programmes using the electronic media, possibly also in regional languages ...' has been written in the form of a recommendation on this issue under the heading 'Academy initiatives'. The students usually do not have the ability to comprehend science literature, which is mostly published in English and one can only imagine the situation when one of these students graduates and becomes a teacher. We must think of the ways and means to break out of this cycle, which is a major cause of deteriorating science education. It is, therefore, better if we do not talk about equity and excellence prior to formulating a concensus national policy on the medium of instruction for science education. The English language has been widely accepted all over the world as the language of science. Why should we not openly and boldly recommend English as the medium of instruction starting at least from the UG level throughout the country. This will definitely help elevate the level of science education and research in our country.

The existing age-old examination system is absolutely poisonous for the growth of science. The way the theory and practical examinations are conducted is extremely dangerous. In fact, science students have become habituated to go into orbit effortlessly. Objectivity in test procedures should be brought in and somehow the feeling of 'great' about science subjects should be infixed into the minds of science teachers as well as students. Furthermore, it is well accepted that the absence of accountability makes the examiners extremly casual and callous while examining the answer books. A transparent examination system may be helpful in alleviating the distrust of the student community in the system. On demand, photocopies of the answer books may be provided to the students. This procedure would definitely induct accountability among the examiners and would make the examination system much more credible.

In specific areas like biology special problems exist. Students of biology get their M Sc/Ph D degrees mainly in subjects like botany, zoology, biochemistry, bioscience/life sciences. There are many more, such as microbiology, biotechnology, physiology, genetics, environmental biology, etc. However, in some states step-motherly treatment is accorded to the students with Master's degrees in Biosciences, Biochemistry, etc., by the concerned Public Service Commissions (PSCs) at the time of recruitment of lecturers for hundreds of colleges, where only botany and zoology are taught. The University Grants Commission (UGC) favours introduction of new courses but never cares to protect the products. This cold war between the UGC and the state PSCs has been continuously ruining future careers of hundreds of students every year. This type of discrimination may dampen the spirit of those science students who opt for new branches of biology, thereby rendering modern aspects of the subject less attractive.

The Academy while constituting the panel should have co-opted some members from state universities, remote universities, and colleges. I feel that the Academy panel itself is totally skewed and has 7 out of 11 members from Bangalore alone. The technique of random sampling for the nomination of panel members may have been more fruitful in pinpointing the real problems faced by thousands of science teachers spread over the length and breadth of this vast country.

The Academy document: A teacher's view

It is heartening to learn that the Indian Academy of Sciences has prepared a Paper on 'University Education in Science'. The paper outlines many steps which the Academy plans to take to improve the quality of science education in India.

The Academy is, by its very nature, an elitist organization of those involved in research in various science areas in the country. Its Fellows are held in high esteem. But I am not aware if any one doing frontier work in the field of science education, *per se*, has been elected a Fellow of the Academy. In that context I feel doubtful if the sudden interest shown by the Academy in the field of education can be fruitful, unless they plan to take the universities and science teachers into confidence at the level of equals.

Before independence, science showed a healthy growth both in teaching and research. This was primarily because the universities were the centres of attention in both. With the rapid growth of many specialized agencies for research in science, with large funding and relatively little external monitoring, the universities came to be neglected, and in successive stages they were emasculated both in manpower and funding. That is what brought the fall in standards in science education. If the Academy is unable to see this background and suggests a reversal of the process, no long-range improvement can be brought about.

As matters stand today, every time an idea to improve something comes up, we tend to think in terms of creating a new island in the ocean of education. The interuniversity centres form one big example. The thought of advanced centres and elite institutions stems from this line of thinking. The Planning Commission report which the Academy has extensively quoted, and to which the Academy Paper appears to subscribe by and large, is on the same line. The reason is simple: the Planning Commission could not identify 'good enough' teachers from the universities (just as the NCERT, for example, fails to find such people from the universities) for consultation, and the result is the report which the Academy Paper quotes in depth. Even as such proposals were afloat, the best of universities gave up undergraduate teaching (and the worst of colleges switched from 'general' to 'honours' courses at B Sc level). In effect, the centres of excellence tended to treat undergraduate teaching as something below dignity.

Limiting myself to physics, I find that the Academy Paper fails to make even a mention of the existence of the Indian Physical Society (IPS), Indian Physics Association (IPA), and Indian Association of Physics Teachers (IAPT) as organizations with interest in the advancement of physics education. IAPT, in particular, has been publishing a monthly journal dedicated to physics education now for over 10 years, and yet, when the Academy Paper proposes publishing a new journal it does not even mention that one such journal exists, and four journals initiated and funded by UGC for this very purpose are also in existence.

The UGC itself has a Panel for each subject, like the Physics Panel presently under J. V. Narlikar. The Panels are supposed to do exactly what the Academy is now planning to step in for. I wonder if the Academy ever thought of consulting or contacting any of the UGC Panels. As one example, for UG physics laboratory, the Physics Panel conducted a Workshop at Mangalore in 1994, which does not find any mention in the Academy Paper, although efforts by individual institutions are listed there. IAPT in 1992 had moved that a Workshop to sort out a Model UG Lab in Physics be held to identify the most educative open-ended experiments, and it gave an initial list (to begin with) after a three-day seminar. The present Physics Panel of UGC has moved to set this into action, and then have it multiplied at 10 places in India for year-round training/orientation of teachers. The Academy Paper does not show that its Panel members are aware of such a move. What they suggest shows utter ignorance of how educational laboratory items are developed. Having been involved with the work of Saraf for over three decades, I know it needs sustained and exclusive attention over many years to get somewhere. Just sitting across a writing table and producing a list of 100 experiments amounts to nothing more than duplicating what the Boards of Studies at some 150 universities have been doing for the last 50 years; it could be worse if the persons involved are leading researchers and not teachers with a special eye.

There is also reference to equity and excellence, whether it is to be *and* or *versus*. This is the reaction of those in the upper atmosphere, who are unable to see the ground situation in science education. Firstly, I see no point in dabbling with a subject which is not my own, viz. social science and democracy. These have their own pressures and consequences. Our decision to improve the quality of science education must in no way be linked with what happens in the social field. Secondly, and more importantly, we must see that science education has three clear objectives: (a) preparing candidates to take up higher education and research in a chosen science field, (b) enabling them to take up various applied areas where science is to be of direct use, and (c) creating general enlightenment and enrichment of mind to be a better citizen of tomorrow. As a recent survey by IAPT has shown, not more than 10% of those who enter B Sc have objective (a). This is nothing to be surprised about. Most of those seeking professional courses have been sorted out, and those that remain enter B Sc largely for objective (c): enlightenment and enrichment.

Here comes the major distinction between how this analysis would be seen by Fellows of the Academy and by teachers. The former would have their eyes rivetted to only students of kind (a), while we, as teachers, have as much, if not more, eye on those whose objectives fall under (b) and (c). This brings me to what has happened in the past few years. At one time the UGC Physics Panel was exclusively manned by non-university personnel. The Curriculum Development Committee of the UGC was manned largely by university teachers, but their eyes were exclusively on kind (a) objective, partly because they had to create a syllabus that should look attractive to top physics people, which means research people, not mere teachers, like me. And with the passage of time, university after university went on revising its syllabus to make it look the most attractive in the same sense; worst, the distinction between a general and honours physics course was wiped out.

Typically, out of some 12 papers of the same trend, if 8 were taken it became 'general', and if 12 were taken it became 'honours'. The difference in the approach and spirit of the two, which is linked with the difference of objectives, got lost. The result has been that the general student is left high and dry, as also the teacher.

Even worse happened at the higher secondary level. The NCERT, mistaking the best research workers to be also the best teachers and educationists, invited several top elite people to head committees to write the syllabus and text materials. I do not at all cast any doubt on their honesty in such selection. These eminent people accepted the responsibility, and I again do not have the least doubt that they did mean doing good service to the society in all honesty. They are all, in my opinion, men of great honour and competence in their respective fields. What went wrong was that they did not realize that education is a separate field of specialization, requiring different talents than only knowledge of science. Further, they were not prepared to give up their current research involvements, and they left most of the work for others to do. Yet worse was that once the manuscript was handed over by them, they did not have control on the get-up, drawings, conduct of examinations, etc. This cascading series has done very considerable damage to science education in India. One has only to compare with the effort of an agency like the Physical Sciences Study Committee in the USA to find how very poorly we have come forth in this effort. I mention this in depth because the Academy appears to be entering the same kind of role, in all honesty, of course, but without quite realizing that education is a different field from research.

Let me repeat that I have the highest respect for the Fellows of the Academy for their contributions to research. I also have the confidence that the proposal they have come up with springs from the bottom of their heart. They really mean to help education in science. In that context, I have a few suggestions to make:

(a) Let them not start a new journal in science, but send their articles and suggestions for improvement in science education to the existing journals. Their frequency can be increased; their volume per issue can also be increased. In fact, even their format can be altered. I am sure the Editors of the current journals will be only too happy to have many of the contributors on their Board of Editors.

(b) Let them use the channels of the UGC subject Panels to initiate new ideas and proposals, rather than create a new power centre of their own. Let them also use subjectwise teachers' organizations as means of executing their programmes. For physics, from IAPT, with over 3000 members spread uniformly all over India, and with its sustained work over 10 years, they can feel sure of all cooperation.

(c) Let us discuss in depth why physics is losing all interest and excitement as a subject to be learnt. In particular, the laboratory component needs to be examined in depth. (But it cannot be a casual matter.)

(d) Let them involve leading teachers from the universities (as distinct from leading researchers only) in whatever they want to do for the advancement of science education.

(e) Let the very idea of creating elite centres for elite students be shelved deep, and let us work for the uplift of the largest masses through dedicated teachers' efforts. The processes of examination, selection of candidates as also the institutions, and the selection of teachers, etc., are all fraught with great danger. They may lead to more fragmentation in the society, and particularly the teachers.

I appreciate the initiative taken by the Academy. The purpose of this correspondence is to get the best out of such a powerful initiative.

OPINION

The Indian Academy of Sciences document on science education in universities: A criticism

V. Sitaramam

I was dismayed when I read the action plan of the Academy for science education in Universities. It is necessary to assess what the Academy proposes *vis-à-vis* what its predecessors have done. The document rightly refers to the Kothari Commission, a large tract that bemoans the state of education even as it stipulates what needs to be done. The Academy document, more prosaic, more clinical and consequently less transparent of its own shortcomings, has no insights. If it has, these are suppressed very successfully[1].

There are three players in the educational scene: the teachers, the students and, most importantly, their homes. Each of these has undergone a sea change in the last few decades the world over. The document reflects neither their magnitude nor the implications. Most importantly, the document offers no justification as to why science education has to be given specific preference. It has some marginal statistics, as a matter of numbers. The reasons behind the numbers are anybody's guess. If

students are not taking up science, what are the reasons? If they are taking up science and not doing well, what are the reasons? Instead of going into a factual analysis of what is the situation, the document considers the simple-minded scenario: put in money where the students are good, the results are bound to improve. A number of instances are cited as patent successes such as the Maths Programme and the Biotechnology Programme. The document does not reflect any of the existential concerns that affect these so-called successful programmes.

So the major concern is money. This country has developed two major arguments in defence of its failures: first that there is never enough money and the second that there is too much population. Education and science are no exception. Good conscience for a scientist, for a Head, for a Vice Chancellor is to get money. Many of our mind-sets are based on expensive fallacies, which are more important to understand than what the Academy has to offer. Let me briefly outline these.

Fallacy of money

Give better wages to teachers and teaching improves. It did not. Easy research money also will not improve research. In an excellent evaluation of an Indian university in an anthropological study, Don Kurtz wrote of how majority of the rural and a great deal of urban teachers are busy with parallel occupations so engrossing that their teaching is a mere avocation. The shocking thing about the university teacher is not that he attends to other jobs. A good many do not. Majority spend their time vacuously without any yardstick of achievement except routine teaching. Someone should do elapsed time analysis of a university teacher (this is more difficult to assess in National laboratories, where timings are adhered to but there is no rule that one should work!). This easy style of living is reflected in the low level of maintenance of buildings and rooms.

It is a sad mistake to imagine that one is complaining about all these. Actually it is a very comfortable situation. There is total lack of accountability. Good manners and departmental *esprit de corps* see to it that no one is challenged. Administration is usually very accommodating. Each faculty member has enough reasons of committees of various kinds, politics, harassment and what not to prevent him from teaching or doing research[2].

Fallacy of perfectionism

This is the major bug bear of Indian educational system. I think that it is time we realize that a great deal of standard teaching requires plain donkey work. If it takes donkey work to teach at the lower levels *en masse*, then either we should be prepared to do donkey work for majority of the time or we should not be ashamed to appoint donkeys to do that. This is what work ethic is all about. Kothari wrote about the requirement for a university teacher. He wrote, in a sense correctly, that a one-hour lecture should require 3–4 hours worth of library and assignment work by the student. That is not easy! If I have to give a *thinking* lecture, original in content (as opposed to an information-laden lecture), based on what I know, without much preparation, I have at most about 5–8 lectures to give per year! Otherwise, I have to resort to existing problems in books or reading assignments to make them work.

If we consider science of today as perfect science, we already lost the battle. We would teach science as a finished polished perfect thing. It loses all the uncertainties, imperfections, greyness of the most exciting part of science, i.e. the developing science. The most damaging aspect of education is that most teachers take the finished aspect of science as gospel truth and consider their job primarily one of giving information. Science cannot be taught without doing it. Alas, it also cannot be done without sharing it. This was why most argued that the universities should be the places for research, a mould we have thoroughly destroyed in this country.

It is not that there are no problems. If we teach science as the grey imperfect thing that it is, we lose most of our audience. A sustained effort at teaching the method of science to M Sc Biotechnology students over 5–6 years convinced me of the futility of it to get it revoked from the syllabus! It is not possible to teach something in isolation when it is not shared by bulk of other teachers.

Fallacy of merit[3]

This country started IITs with the hope that if we take the best and put them where they do better, everything will be alright. What have they done after IITs? If intelligent people need to be doing science, why is it that so few of our brethren in IITs have impressed these growing and glowing minds towards fashions and passions of science and research? Why do many opt for the Citibank? The students who get into IITs by grind do so under a number of compulsions, parental pressure being the most, peer pressure the next. An individual's choice for a subject is dictated not by active interest but by the current mores and the order of merit. Merit does not seek personal involvement. What has recognition of merit led to? The evidence is clear that any recognition leads only to easy life. So does lack of recognition, which blunts ambition. What we fail to see is that by sequestering them into a privileged community, we have raised their expectations without a provision for integration.

Fallacy of preaching

Most of us think that since we are doing science, what we are doing interests our students. There is also this law of diminishing returns in science. If you have done science, if it is the best thing for you, so be it. If an area has rewarded you, it need not interest the discerning youngster. The student wishes to examine his returns. Secondly, he wishes to know if you work (≡ succeed).

Since most do not work by themselves in the absence of students and assistants, and many do not work regardless of students or assistants, the question of science in this country is limited to what can be done by way of Ph D programmes, which are primarily remote-control operations. We are talking about a very inexperienced work force, whose life is limited to 4–5 years, of which 70–80% is lost at the formative period and hardly 10–20% of the professional life goes into research. If we consider countries with much lesser number of people, they have achieved much more. The difference is not in overall numbers but in working numbers. We have the least of the latter. These cannot enthuse the newer entries towards anything other than a retired life.

Fallacy of rewards

Any reward system that is not heavily backed by peer pressure is a disincen-

tive rather than incentive. Scientists would be no more than dictators of tin-pot republics displaying rows of medals that were not won in any battle and were largely self-endowed. Even then, the real danger is not in the awards but in the deliberate creation of pecking orders. Lack of authenticity, the main plague of Indian science, leads to many alternate means to develop science and education, all of which are doomed to fail and they have. The best of the Indian institutions are imitative. In the absence of originality, and even more, authenticity, where does excellence come from?

There is something about the past and present in the Indian scene of science and education that is worth pondering over. The key word is authenticity. I refer first to the Kothari Commission and then to the psychology of the modern student.

Fallacy of degradation

One discovers corruption and degradation as part of the middle-age crisis. Is our science deteriorating? *Or is the middle-age science deteriorating*[4]? I would strongly recommend a reading of Cicero to anyone who talks of contemporariness of corruption and degradation.

When we are younger, we do see that things are not going too well. Being younger and optimistic, we let things be and get busy with whatever we can do. We soon run out of time. The crisis of middle age is when we are running out of new things to do and running even more out of the time available to us to find new things to do. A clear case of burnt out options! When we find that time is finally getting the better of us, the illusions fast disappear and we despair of the things that would never be. How well does the government recognize science? How about a new NRI university? We forget that we represent a constituency and a trade union and we forget that we have vested interests and we also conveniently forget that we have larger responsibilities. Relevant work in this country is shunned since it involves commitment. Why do we blame our politicians for monopolizing the public interest? Do we share any? It is possible to live with all these imperfections among ourselves. But the instant we arrogate ourselves to the keepers of conscience, we certainly have gone into a severe level of delusion. Too many of us sit on too many committees too often as yesmen. We not only achieve little but also allow things to slide far. Kothari was deeply worried about this docileness, this lack of comprehension of larger scheme of things, this apathy and cynicism and the lack of ability to challenge the purpose.

Kothari's forgotten plea

The conceptualization of a modern Indian university in the Western mould was literally a thought in the wilderness. It was stated that universities control colleges that are not even in the same province. It was contrasted with Oxford and Cambridge and the British thought that one day these problems would disappear when colleges do not depend on remote control by distant universities.

The UGC came into being and a lot of universities followed. All of it was inevitable and did not worry Kothari. One thing worried him most. It was the independence of thought. He was deeply concerned about the fearlessness of the Indian teacher. In fact, this is among the few personalized and important topics that he devoted most attention to.

Obviously, what Kothari was worried most about was the lack of individuality in the teaching community in this country, because that is what he wrote about. He eloquently asked for it since this is what we did not, do not and will not have. We actually confess this gently all the time. When we say that we have failed to develop adequate peer review structure in the country, do we not mean that we have become mercenaries, with no love except for our own gains? We at least admit our lack of honesty of purpose.

I take it that sycophancy was what worried Kothari most. The British loved it. The colonial India had its ethical roots in Rudyard Kipling and sycophancy[5]. Independent thought was possible. Fearlessness was most definitely not[6].

Kothari's errors

The Kothari report wielded considerable influence. We had M Phil degrees as a further stepping stone between Masters and Ph D. There was this pervading mind-set that, in order to do something new and original, it requires proper preparation and that this preparation can be imparted by the wise and holy. It is now common knowledge that even a Masters degree is a waste of time if the B Sc is okay. The way to learn to swim is to start swimming and not prepare lecture notes on swimming. So also in research. What do we find about M Phils? These are either clocking time to go abroad or get married or indecisively waiting for better opportunities like MBA or IAS. The right approach to research is to get going and not to prepare for it.

The second error of Kothari was in that he romantically believed that production of some high-powered, expensive structures for education for the meritorious would enhance the capabilities and the nation would benefit. Yes and no. This class of problems has at best a percolative effect. This contributed more to the baseline than to the top performers. Nation building requires a lot of chores that may not have much market value. For instance, who would go to regional colleges to teach? When the USA stopped the preferential import of engineers, a lot of them stayed back and now we have some Ph D's teaching in colleges, which was never the case. Other than a marginal percolation, have these edifices contributed significantly (considering the money poured in) to the growth[7]? The error is not in asking for merit-oriented establishments of high cost and fidelity in performance. The error is in assuming that such structures would be possible in a time-lasting manner and that the results would be independent of the social circumstances and market forces. The kids who study there come from families and families have aspirations. The question is, do they match?

The major problem lies in the romantic notion of merit. Merit yields results (for the individual) and results lead to power. The shortcut is that let merit be assumed and not won. We have only tenured positions. Who cares whether a qualified person does *not* work or an unqualified person does *not* work. The end result is the same. Universities have offered us exactly this. This heady brew of nonperformance. There is no academic audit in any university. What is in question is not merit but the attitude to the job at hand. Merit does not ensure that and, therefore, it is not a sufficient condition for performance. We have not evolved a system that ensures merit as well as attitude.

The market force logic

When we were young (I grew up in a University Campus), everyone told us that it would be good to take up a professional course since jobs are easier to get and assured income is what life is all about. While that may well be, the academics were also seen to be doing things on their own and appeared to be equally comfortable. While emphasizing the material things, there was a simultaneous de-emphasizing of their primacy in life, we have not heard in schools and colleges anything other than that education is everything and everything else is of less worth. A mind-set that persisted by frequent repetition. The market force was always there[8]. Only, it was not put on a pedestal like now. The best always exploited the best of the market since they are both savvy and have highly developed manipulative skills (as any teacher would know). By de-emphasizing the market forces, the second best, though with higher motivation, got into education and related areas, including government jobs. Now the industry, which is still considered second-rate in the country, is picking up these people vigorously. So enrolment in science will plummet further since new markets are opening up for them. How many are taking language and philosophy? Do we need any lesser brains in these areas, however few may be required?

What do we do today? In biotechnology, we are supposed to encourage students to go to industry. Since we speak of industry, the students ask whether they can have the cake and eat it too. Can they finish the Ph D while working for an industry and so on. Amazingly, few students think beyond the self-reference that they owe something to the industry that is going to pay for their upkeep. The Indian student is brought up in such a sheltered manner that no one told him that there are no free lunches in the free market economy. Little emperors!

Whatever we do for Indian science, elitist attitude will destroy performance. It takes away opportunities from those who need it most and fritter it away on those who have the least commitment, statistically speaking. Science and knowledge are based on performance. Merit is based on promise. These are not the same thing. Power is based on actualization by simply being there i.e. where it counts. Merit and performance are routes to power. Neither individually nor both together are sufficient conditions for acquiring power. Amongst the proxy routes is what we call nepotism, a word we reserve for the individual. When a group is involved, we call it social action and equal opportunities employment. There is no point in getting our hackles raised. All these explicity recognize that being there is what matters in society and, therefore, in the absence of critical performance criteria, everybody will insist on equal opportunity to get there.

Teachers, the romantic diehards

Pune University has an interesting experience, since it housed till recently zoology and biotechnology in the same department, the former by local merit and the latter by national selection. As an insider, I tried to evaluate what motivates the teachers the most. The biotechnology students represent, on an average, a more cosmopolitan cross-section and perform better. However, one needs to listen to the teachers about their attitudes to these students. The university teachers, unlike the guest lecturers from national laboratories, react differently. First of all they complain often that these students are less sincere and more arrogant. When the same complaint comes too often from even the better teachers, one worries. What I saw was an amazingly simple matter in academic psychology. The faculty claim that while a lot of teaching is drudgery, the tedium is made up by the few students who perform very well. The usual university students tend to be of uniformly lower level, barring these occasional performers, and their motivation also tends to be uniform. In this low-average class of performance, the occasional good student could bring tears to the eyes. Of course, it is not as simple as that. Actually many of them are exceptionally nice kids, often very sweet and most polite. They are quite diffident and yet when handled gently can be motivated to a higher level than one would consider it possible. On the other hand, the biotech students are, on an average, better in their intelligence, with less of an excuse for goofing, which makes the teachers mad. More than 50% of them have no interest in what they do once the novelty of Pune life wears off. Thus, we see better performers with a higher level of variance in their motivation and performance among the biotechs. It is definitely more painful to see a better student being a nonperformer than a lesser student. Since such a possibility arises more in biotechnology than in zoology, the attitudes of the teachers too have shown variable level of weathering towards these students. Better students breed cynicism faster in teachers than lesser students. The culprit is the variance in attitudes at constant capability! This was confirmed by some IIT faculty as well in personal discussions.

We have occasional departments in the universities with considerably better cross-section of teachers, at least on an average. The student inputs are no better. However, the teachers generally do not innovate in teaching simply because this is a bother. That is what worried Kothari. This oppressive (conventional) wisdom that aborts action even before it is contemplated!

The psychology of nonperformers

In the final analysis we need to contend with nonperformers. Lack of intelligence does not correlate well with nonperformers any more than intelligence assures performance. The key factor is the attitude. What drives people to nonperformance? Are they made or are they bred?

We cry a lot about changing values and loss of traditional modes of living for all the wrong reasons. In the larger joint families, the average attention on a single child is negligible. There are so many. Largely the children look after themselves with marginal contact with adults. What happens now? With the increase in nuclear families, the child (we two and ours two!) now has two pairs of grandparents and one set of parents who dote on the single or the well-spaced two children. The parents, both working, come home with a heavy guilt feeling that they are neglecting the children. This view is heavily reinforced by the ageing grandparents, whose justification for hanging around is that they are needed to fortify (or disable?) the minds of the younger with their notions (when we were younger, we rarely spoke to the elders and, fortunately, they spoke to us even more rarely) since the parents are neglecting the children. The guilt complexes lead to overindul-

gence of the children. Thus, little emperors are born. Once born and bred, they stay! China is reeling under the impact of these little emperors. I have interviewed a large number of students now. I have no doubt that we have our own growing numbers of little emperors.

We have been devoid of performance in this country for a long time. There must be deep-seated reasons here for this. Individual excuses or else a social reason like population or caste cannot be made responsible for it. *We need to consider it a matter of highest priority as to what makes our youngsters untick. We need to determine the behavioural strategies we adopt with great care as parents, teachers, grandparents, or what have you, that rob the children of their initiative*. There are many things that we do not know about our youngsters. Most of all we do not know how much of insecurity is critical and undamaging to the youngsters to ensure their performance. We need to consider even their social mores, driving force for smoking to harder habit like drugs, AIDS etc. Unfortunately, there are few meaningful studies on a cross-section of people that represent tomorrow.

What we require is a professional psychological survey aimed at the performers and the nonperformers. In spite of the fact that I believe that I have seen a reasonably large sample of semi-performers (as in biotechnology as well as in IITs and so on), I feel it is very prudent to have some assessment of what is going on. We need thumb nail sketches of what the parents think. We need to know what made the students opt for what they did. Above all, we have to examine why the Indian science student has delayed social puberty. I have seen several students react to their first time out-of-home atmosphere as if there is no tomorrow for catching up with all the lost time. We have social dimensions and problems of a large kind that determine the behaviour of the youngsters.

This is where the notion of perfectionism hurts. Science is perhaps the only avenue in academic life in which a mediocre person can do well. Arts and humanities are brutal. To do well you have to be very good indeed. Instead of emphasizing performance that we should, we emphasize promise. There is no other way to understand the Academy document. Performance requires motivation and motivation is in the realm of psychology, an aspect of human beings that the Academy was deafeningly silent about.

The approach of the Academy is not without blinkers. First we have those who take up science because they have not been pushed enough to get into competitive exams. Then we worry about their future since we find the options diminishing. A lot of ideas get generated: NRI universities, new initiatives for science and so on. In all this we ensure the basic attitude that spending money is good enough.

The action programme by the Academy: How justified is the fund allocation?

The Academy followed up the recommendations of the Planning Commission and suggested spending some 25 crores on the gifted, 60 crores on the less gifted and another 30 crores on the rest. At the face value, it looks reasonable. Have another look and you would be horrified (Figure 1). The numbers look alright grossly. The Academy is suggesting spending some Rs. 15,000 per capita on some 700 students of the tier I per year, some Rs. 1000 per capita on some 25,000 students of the tier II and some Rs. 100 per capita on some 1,23,000 students – the rest. These being 1989 figures, an upward revision of some 5–8-fold would be in order. I have no doubt that there is no ill will and the recommendations were made with the best of intentions. But then, good intentions are what they are. Where do they lead us? On the one hand, we are talking about 60 crores (tier II) of the same level of incomplete education, while we are offering 30 crores of placebo *as a political gimmick* to concentrate 25 crores on the (?) desirables. We are talking about, with a straight face, creating a yet another group of not-so-little emperors who will also become self-seeking snobs. They would also be alienated and subservient to all that is Western, with a goal no more than to dwell on a postdoctoral fellowship abroad. For a few more dollars! Yes, Kothari had a justification then. The performance outcome of higher citadels of learning towards science education, or even education in general, was not understood then. The age of innocence may be forgiven. Yet we are talking about reinforcing majority of these 'failures' (the Academy was also clear

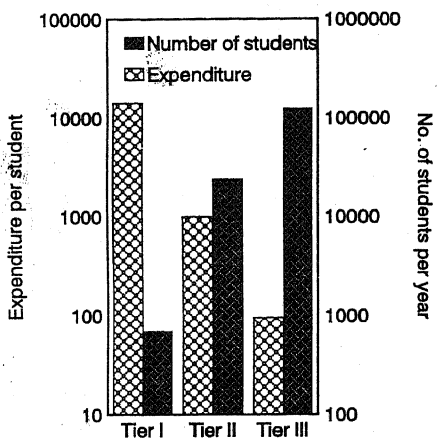

Figure 1.

that these were rejects of an earlier selection process) with a system of education so far removed from their own brethren and for which they have done mighty little to earn.

When they graduate, their expectations will be very high. We have been fighting a losing battle with the biotech students and their attitudes, of levity and lack of sense of proportion. We created an artificial market. It was not bad, insofar as the pressure was kept high on them and they were made to work, such that even routine practicals ran past midnight. When relaxation has set in due to inadequate induction of new faculty, and the change in attitudes with time, we find that even their CSIR–UGC scores have begun to dip. What the Department of Biotechnology has done is losing an excellent initiative, and not help setting the norms. Universities have their own momentum for the inevitable downward slide and oblivion for any programme.

What should the Academy do?

The intelligentsia in this country can achieve more for this country, if they display greater humility. If not, we have these recurring and persistent images of Don Quixotes running at wind mills.

I think that the Academy should continue to promote debate and help provoke people. It certainly provoked me into writing this, possibly much against better judgement. It should have definite and tangible goals that help ideas and proposals for school education, videos, etc. It should also learn from the

existing experience in media management. It is time we analyse and tell the UGC how poor many programmes on the countrywide classroom are. The Academy should primarily help motivate any and all programmes that are based on individual initiative.

Above all, the Academy should stop worrying about excellent science and start worrying about existing science and the existing practitioners. Existing problems are there only because the available solutions do not work. A recurrent problem often requires a drastic change in the mind-set. The Academy also should stop worrying about NSUs. We have built many edifices. There will be more. If we are more worried only about losing the piece of cake, we will have no moral justification for the stand we take. Is all the UGC money going to teaching departments and to equip them better? Have major chunks gone elsewhere?

Is there a definitive, prospective course of action urgently required? Yes, I believe that it is time we get the educational system examined by professionals, including sociologists and psychologists. What we need most is painstaking definition of standards in all that we do and the minimum that we can tolerate. *It is the minimum and only the minimum that we need to define.* The government will not help here since it caters to a different constituency. Only we can help ourselves. Above all, it should also help develop standards for rating performances at all levels. Armed with appropriate surveys and relevant analyses, such an effort may bring out some clarity on where to focus our efforts for maximum results. Another area is to begin a serious exercise in cost-benefit analysis and a realistic appraisal of minimum funding for all universities for given courses. The newly started National Assessment and Accreditation Council has aspirations and plans in this direction, which would require considerable help from the academic community.

Centralization of education was inherent to the Academy's idea of picking a few as the best students in science. It has its evils and is even nontangible due to the displacements involved. A larger goal may be to take higher education out of concurrent list, if we have to survive the competition following liberalization, since we simply have to do better. In any event, the solutions run deeper than realized in the Academy document. It is time we shed the proven unsuccessful paths and exercise the same quality of vision that we envisage for the future students.

Notes

1. Peter Medawar in his *Advice to a Young Scientist* remarked that there have been two preceding instances wherein an advice to the younger was attempted. One is Polonius' advice to his son in *Hamlet*; that gives the basics of noninvolvement . . . 'neither a borrower nor a lender be'. A later effort was Lord Chesterfield's advice to his son, which, aptly summarized, taught his son the behaviour of a courtier and the morals of a whore. In attempting to advice the younger, it was necessary for Medawar to steer clear of the shortcomings of his illustrious predecessors. So he came up with a book that tells you how to excel in science if you are already born with a silver spoon in your mouth!
2. The Academy wrote of conveying the excitement of science to young minds. Pooh! In a class of 100 students or more, teaching the same topic for over 25 years, what excitement does one convey and to whom? Even if one starts well, how long will he sustain?
3. 'I am profoundly suspicious of the "A" man. He can say back what you want to hear in an examination, and' . . . 'you must give him his "A" if he says it back; but the ability not to say the willingness to give you back what is expected of him argues a certain shallowness and superficiality. Your "B" man may be muddle-headed but muddle-headedness is a condition precedent to independent thought . . . ' A.N. Whitehead, *The Dialogues*.
4. Or is that since Fellows of Academy come into being in their middle age, there is a coincidence in the way things are perceived to be wrong?
5. Ramanujan was the ultimate example of colonial legacy. The moral of Ramanujan is not that Indian genius exists. The moral is that the only salvation for the Indian scientist is International science, where he will have a better and fairer chance than in the Indian scene.
6. This is a tradition that is not lost to this date. Rotation of headship (of a department) does not matter. Having spent nearly a decade in a university, I realize that it is merely of rotation of one to whom obsequiousness must be tendered to. A well-practised ploy to a countryman to whom polytheism is deeply enshrined in the heart.
7. It is time someone does a cost–benefit analysis of educational structures the same way as we have done for dams. Taken the overall scenario, the cost–benefit analysis showed that development is not without cost. The cost–benefit analysis should take into account the cost of diverting money and personnel from the educational system and the effects on the dilution that ensued.
8. 'I do not believe that the modern parent of any class is more mercenary than his predecessors. When classics was the road to advancement, classics was the popular subject for study. Opportunity has now shifted its location, and classics is in danger. Was it not Aristotle who said that a good income was a desirable adjunct to an intellectual life? I wonder how Aristotle as a parent would have struck a headmaster of our great public schools. From my slight knowledge of Aristotle, I suspect that there would have been an argument, and that Aristotle would have got the best of it' A. N. Whitehead, in *The Aims of Education*.

SCIENTIFIC CORRESPONDENCE

Development of cultured tomato anther to a fruit-like structure accompanied by *in vitro* ripening

With a view to regenerate haploid plants of tomato, anthers carrying microspores at uninucleate stage (buds of 8–10 mm) from glasshouse-grown plants of cv. Arka Saurabh were cultured *in vitro*. The medium comprised Murashige and Skoog[1] inorganic and organic constituents, 3% sucrose and 0.25% gelrite (pH 5.8). Factorial combinations of kinetin

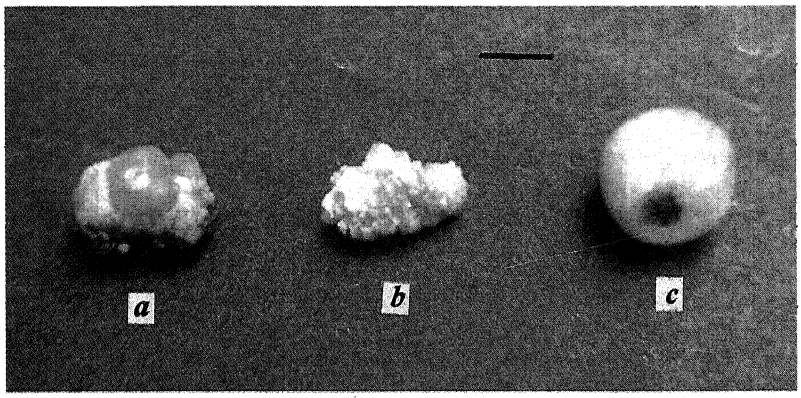

Figure 1. Figure showing pseudofruit at 7 months from culturing of anther (*a*), a half ovary, two months from culturing (*b*) and a normal fruit two weeks from pollination in field (*c*) (Bar = 1 cm).

(0.05, 0.5, 5.0, 10.0 or 20 μM) with equimolar or higher concentrations of 2,4-dichlorophenoxy acetic acid (2,4-D) or indole 3-acetic acid (30 combinations) were used. A total of 32 anthers were cultured per treatment, half of which were incubated under continuous darkness and the other half under 16 h photoperiod (20–30 μmol m^{-2} s^{-1}) at 26 ± 1°C. A limited proportion (30.8%) of anthers showed swelling, of which some exhibited callusing in 3–4 weeks irrespective of the hormonal constitution or incubating environment. Such anthers were transferred to a fresh medium of the same composition at 6 weeks. One swollen anther on medium containing 5 μM kinetin and 10 μM 2,4-D and incubated under 16 h photoperiod swelled up in another 6–8 weeks resembling a small half tomato fruit. Three lobes were there on the upper side and the bottom was flat with reminiscence of calyx-like structure at one end. The pseudofruit on subculturing to fresh medium showed further enlargement (about 20 mm long and 10 mm thick), after which the growth ceased. The ripening process began by 6 months from initial culturing and was a slow process. The top lobe turned fully red while the side ones remained yellow/orange.

In order to verify if the structure resulted from accidental culture of an ovary, a number (200) of split ovaries were cultured on the medium with the same composition. None of these developed to a fruit or a similar structure. Instead, they went into callusing. The pseudofruit was different from normal fruits. While the former was lobed, the normal fruits from field-grown plants were smooth.

Cross-section of the half-ripe pseudofruit showed no placenta or ovule. The inside was full with firm tissue. On the other hand, the normal fruits had ovules attached to placenta embedded in a mucilaginous matrix which was not connected to the outer wall/pericarp (Figure 1). Histologically, the pseudofruit comprised of closely packed parenchymatous cells. The division between lobes was marked with still closely packed cells. The cultured ovaries on the other hand showed a thick mass of tissue in the centre with no distinct cells at the same (× 10) magnification. The outer callus exhibited loosely packed parenchymatous cells. The observations confirmed that the pseudofruit had originated from a cultured anther, with the anther lobes forming the fruit lobes, which is not a typical characteristic of the variety in question. Subsequently, a large number (over 1000) of anthers were cultured under similar conditions, but none showed a similar response, suggesting that this could be a rare phenomenon.

Gresshoff and Doy[2] observed the development of haploid callus cells in tomato to seedless pseudofruits. The present observation is different in that one tomato anther developed into a fruit-like structure. Homeosis, i.e. the expression of one type of organ in the site of another one[3], has been reported in several instances in nature and in isolated cases under *in vitro* conditions. They often appear as mutants[4–7]. Homeotic transformations could also be induced by environmental factors or by interplay of phytohormones. Fisher[8] observed transformation of stamen to ovaries and of ovaries to inflorescence in wheat under short day conditions. Rylski[9] transformed stamen of capsicum flower buds to carpels (with ovary, style and stigma) through treatment with gibberellic acid. Stamen and stigma-like structures, functioning like original units, were induced from receptacle tissue of tobacco *in vitro* in the presence of kinetin[10]. The present observation is different from these in that the *in vitro* cultured anther developed to a seedless pseudofruit just in external appearance and in ripening. No carpels or ovules were present. Such teratological specimens can be useful in interpreting pathways of development. Attempts to reproduce the results were not effective as the specific inducing factor was not exactly understood.

Genotoxicity of 'gudakhu', a tobacco preparation used in Orissa

'Gudakhu' is a paste-like tobacco preparation the ingredients of which, besides tobacco (10%), are molasses (35%), lime (7%), red soil (a particular type of reddish soil available locally, 28%) and water (20%). During use it is rubbed over teeth with a finger tip. Its use is highly prevalent in Orissa and neighbouring states; in Orissa every third person is addicted to it. Persons are known using gudakhu for 40 years or more, and as many as 20 times a day.

Experimental and epidemiological studies have conclusively proven carcinogenic, mutagenic and clastogenic potential of tobacco and tobacco products[1–5]. Recently, a significant increase in the incidence of micronuclei has been recorded in exfoliated cells of buccal mucosa of habitual users of gudakhu[6]. Acetone extract of gudakhu (AEG) has also been proven to be genotoxic by us in mouse bone marrow system using chromosome aberration, micronucleus and sister chromatid exchange assays[7]. In view of the widespread and chronic use of gudakhu, it is worthwhile to study its genotoxic effect following repeated treatment. Bone marrow is a proliferative tissue and hence fails to provide correct information regarding genotoxic efficacy of an agent following chronic exposure. Chromosomal damages recorded in bone marrow cells at a particular sampling time following chronic exposure constitute the damages caused during the cell cycle prior to harvest, not the cumulative damages for the entire period of exposure. Sometimes an agent may go undetected in bone marrow cytogenetic assay following single treatment, particularly if it has low effect. Analysis of micronuclei (MN) in peripheral RBCs of mice, however, provides a very simple and important assay for evaluation of genotoxic efficiency of an agent following chronic exposure[8–10]. The present study deals with the evaluation of genotoxic effect of AEG in mice following repeated treatment for different periods using the micronucleus test (MNT) in peripheral erythrocytes.

Seven albino Swiss mice (4 males and 3 females) aged 10–12 weeks were employed. Gudakhu of 'Samaleswari' brand was purchased from the local market. Details of the extraction procedure have been presented elsewhere[7]. In brief, gudakhu of known weight was homogenized in a mortar and pestle with acetone, extract was filtered and the filtrate evaporated to dryness through vacuum desiccation. A freshly prepared dry pellet of known weight of gudakhu extract was suspended in an appropriate amount of distilled water and the suspension fed to mice by gavage. Animals were fed with a dose of 300 mg/kg (the highest dose tested in our earlier work[7] and having no visual abnormal effect on behaviour of the animals) of the dry extract once daily for 4 weeks. Blood was collected from the tail vein of each animal, without killing it, at the end of each week during the course of treatment and also on day 0 just before starting the treatment, and smear was drawn on grease-free slides. Blood collected on day 0 served as control sample. Thus, the same animals provided blood samples for control as well as for different test weeks of the treated series. Air-dried smear was fixed in absolute methanol for 15 min and stained next day in Giemsa diluted (1:10) with buffer (pH 6.8) for 10–15 min. Erythrocytes (both polychromatic and normochromatic) were examined for the presence of MN and the frequency of micronucleated erythrocytes (MNRBCs) was determined. For each sampling point 35,000 erythrocytes were scored from 7 animals (5000 from each).

Micronuclei were invariably round in shape and were of varied size groups (Figure 1). Never was an erythrocyte found to contain more than one MN. The frequency of MN increased significantly, compared to the control value, in all the test weeks. For weeks 3 and 4 the values were about 3 times the control value. Further, the increase showed a good positive correlation with the time course of chronic treatment (Figure 2).

The results clearly reveal positive genotoxic effect of AEG and support our earlier findings[6,7]. MN are induced by clastogenic effect or spindle dysfunction. The former generally results in induction of single micronucleus while the latter in multiple micronuclei. As in the present study, no case of multiple MN was encountered; the MN are supposed to have resulted from the clastogenic effect of AEG, and this finding is in accordance with our earlier one[7]. Elevated incidence of micronucleated polychromatic erythrocytes (MNPCEs) was also noted in peripheral blood of

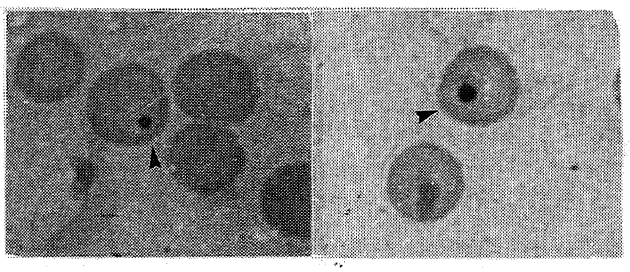

Figure 1. Micronucleated RBCs.

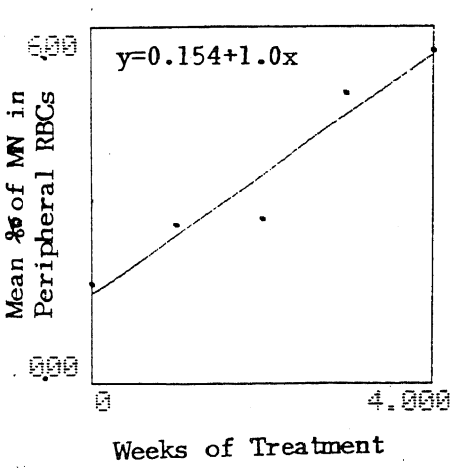

Figure 2. Linear regression curve showing the relation between the number of weeks of chronic treatment with gudakhu extract and the incidence of micronucleated peripheral erythrocytes ($r = +0.965$, $p < 0.001$, $a = 0.154$, $b = 1.00$).

new-born mice the mother of which had been exposed to tobacco smoke daily for 1 h during the last 6 days of pregnancy[11]. Recently, equal incidences of micronucleated peripheral reticulocytes (MNRETs) and bone marrow MNPCEs in mice treated with mitomycin C have been reported, though the induction of MNRETs was delayed by about 12 h compared to bone marrow MNPCEs[12].

In some strains of mice, unlike in most of the mammals, including humans, MNRBCs are not removed by the spleen; they remain in circulation[9,10,13,14]. As a result, MNRBCs get accumulated in their circulation. The RBCs of mice survive in the peripheral circulation for about 4 weeks[13]. Hence, repeated treatment is expected to exhibit gradual increase of the incidence of MNRBCs up to 4 weeks. Positive and significant correlation between the incidence of MNRBCs and the time course of chronic treatment obtained in the present study can be explained from such a behaviour of RBCs in this strain of mice.

Our results prove the uniqueness of this simple system[9,10], which is helpful in monitoring even weak clastogens following chronic exposure. Further, in this assay the same animals can provide blood samples, as in the present study, for control as well as treatment data for various periods. However, both polychromatic and normochromatic erythrocytes need to be considered.

Conclusion

Genotoxic effect of acetone extract of 'gudakhu', a paste-like tobacco preparation, has been evaluated using the micronucleus test in peripheral erythrocytes of mice following chronic exposure. A dose of 300 mg/kg of the dry extract in aqueous suspension was fed to mice once daily for 4 weeks. Micronucleated erythrocytes (MNRBCs) were scored from smears of tail vein blood collected just before beginning the treatment course and at the end of each week. The frequency of MNRBCs increased significantly in all the test weeks and showed a good positive correlation with the time course of treatment. The result has been discussed in the light of the fact that MNRBCs are not screened out by the spleen in mice, and this assay proved to be very important, particularly after chronic exposure.

Azolla sp. from the Early Cretaceous of Cauvery basin, South India

A new record of *Azolla* sp. based on megaspores and massulae from the Late Albian (Early Creataceous) of the Pondicherry area in South India is presented in this study. The massulae are with characteristically circinate and septate glochidia. This is the oldest record of *Azolla* known to date.

During a palynological study of the Early Cretaceous carbonaceous shales from a depth of 32.4 m in bore hole BH/23, drilled by a private party for ground water, 1.3 km west of Kattarambakkam village in Pondicherry area in South India, the authors have come across a number of well-preserved massulae of *Azolla*, a water fern, along with varied spore and pollen taxa. One of the palynoslides also shows fortuitously a fairly large megaspore with a thick mat of hairy (tomentose) perine in which are seen entangled five massulae (Figure 1 *a*). All these massulae are characterized by circinate glochidia. Similar massulae have not been recorded to date from any horizon in India.

The following are the details of this new find of *Azolla* sp.: (i) megaspores about 500 μm in diameter, extremely thick-walled, wall up to 30 μm thick; stratification not clear as the specimen is dark, dense and more or less opaque; (ii) outer layer of megaspore wall representing perine well developed and made up of thick felt of delicate hairs (tomentose) (Figure 1 *a–c*); (iii) number and nature of floats could not be deciphered; (iv) massulae attached to perisporal hairs of megaspore, oval to elliptical or irregular in shape, 85–214 μm in longest dimension, 54–125 μm in shortest dimension; (v)

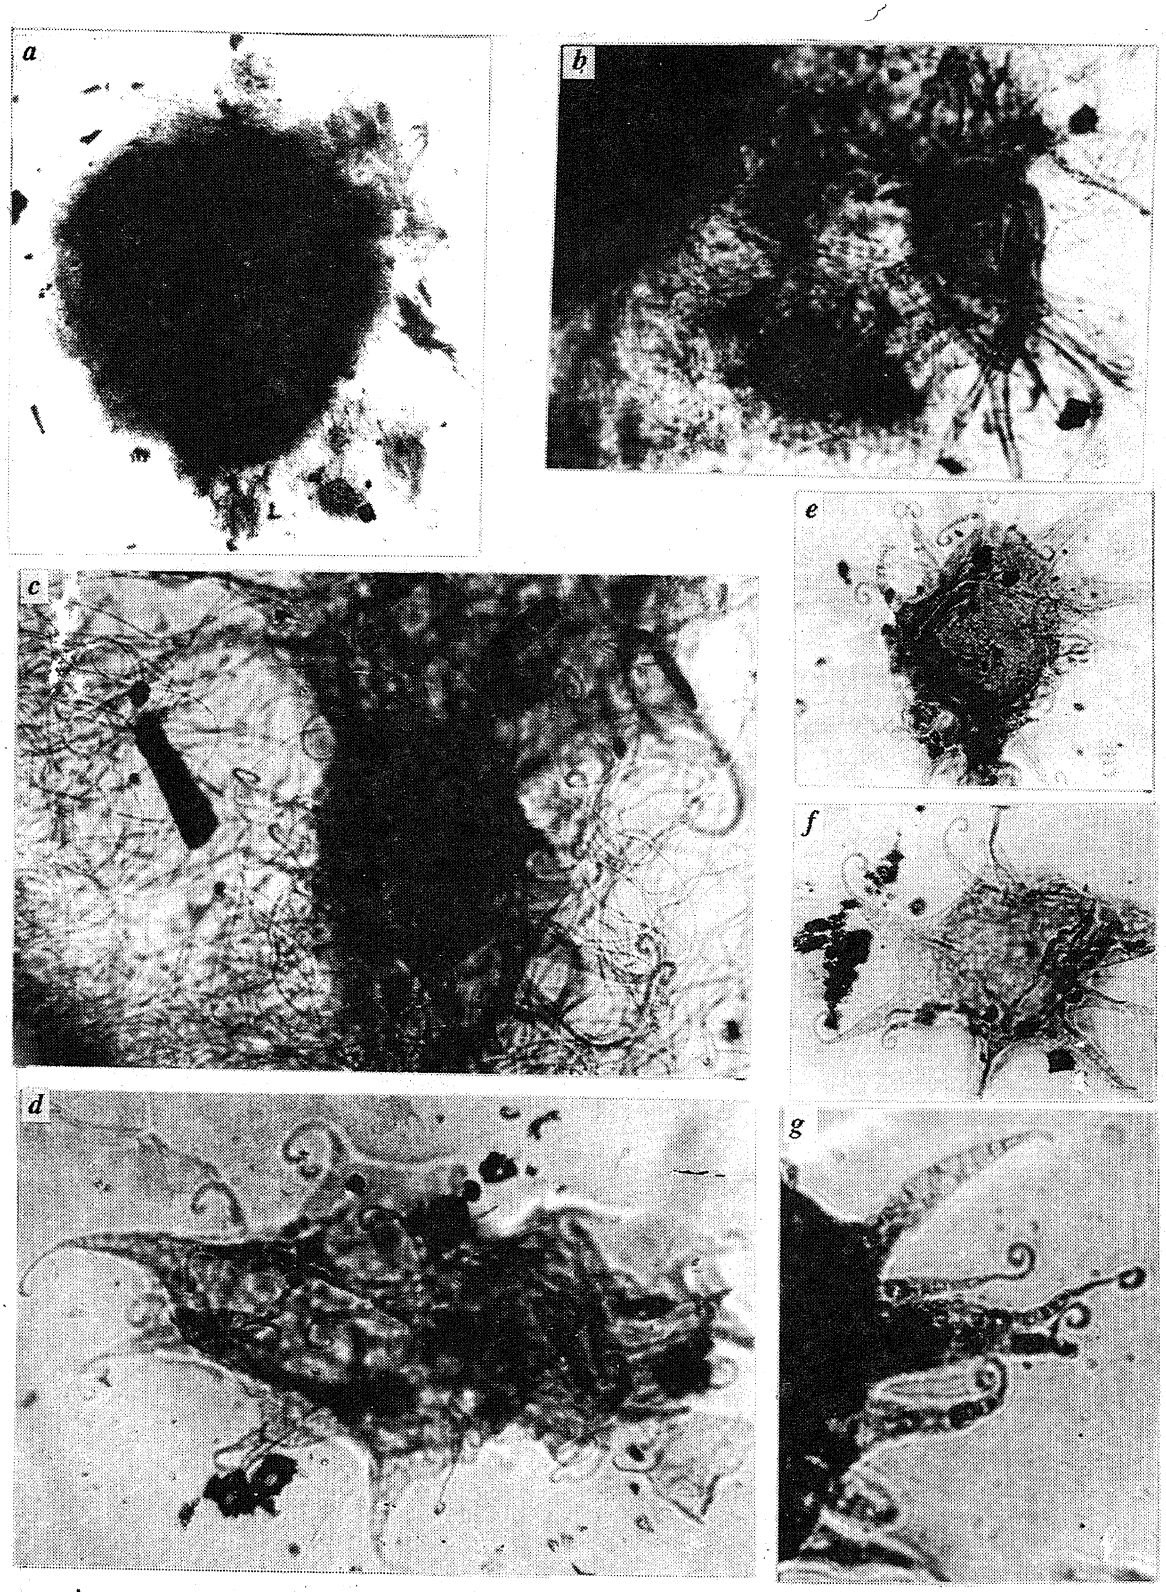

Figure 1. *a*, *Azolla* sp. Megaspore surrounded by massulae (×100). *b*, *c*, Part of a megaspore (enlarged) showing perisporal hairs with massulae entangled (×300). *d*, Massula with circinate, septate glochidia and a microspore (×400). *e*, *f*, Smaller massulae (×300). *g*, Glochidia enlarged (×500).

surface alveolar and foamy, (vi) glochidia many, 7–10 μm broad at base, 42–60 μm long, filamentous, mostly circinate at apex, usually with one gyre, occasionally with only a partial gyre, distinctly septate (Figure 1 *d–g*); (vii) basal part of glochidion often robust; (viii) microspores 1–3 per massula; 32–50 μm in diameter (few up to 60 μm), thick-walled, psilate to locally granular.

The spore and pollen complex recovered from the samples which contained *Azolla* remains is represented by the following significant taxa: *Lycopodiumsporites austroclavatidites*, *Ceratopteris equalis*, *Dictyosporites speciosa*, *Crybelosporites stylosus*, *Cicatricosisporites australiensis*, *Plicifera* sp., *Coronatispora perforata*, *Contignisporites glebulentus* sp., *Appendicisporites tricornitatus*, *A. distocarinatus*, *Schizosporis reticulatus*, *Triporoletes reticulatus*, *T. radiatus* (common), *Tricolpites* (few species), etc.

This assemblage is strikingly similar to the palynoflora of the Late Albian deposits of the Cauvery basin[1]. The age of the *Azolla*-bearing deposits under study is, therefore, assigned to Late Albian (Early Cretaceous). Hitherto the oldest records of *Azolla* (*A. circinata*, *A. montana* and *A. geneseana*) were from the Maestrichtian (Late Cretaceous) of Montana[2], USA, and Alberta[3], Canada. Though resembling the present specimens of *Azolla* in the possession of circinate glochidia, the American *A. Circinata* is distinguishable in its non-septate and much shorter glochidia. The present record of *Azolla* thus constitutes the oldest and the massulae-bearing circinate and septate glochidia probably represent the primeval condition. A detailed study involving the nomenclature and evolutionary aspects of the new record of *Azolla* sp. is in progress.

Angioarchitecture of the glomerulus of a swamp catfish, *Chaca chaca* (Ham.) (Chacidae, Siluriformes)

Glomerular vascular architecture of a freshwater swamp catfish, *Chaca chaca* (Ham.) was investigated using corrosion vascular resin replica, a novel method to study angioarchitecture of an organ at capillary level. Each afferent glomerular arteriole (AGA) ramifies to form tortuous capillaries of almost round glomerulus. The tortuous glomerular capillaries converge to form efferent glomerular arteriole (EGA) of almost similar dimension.

The past light and ultrastructure studies have revealed fenestrated glomerular endothelium[1], the nature of podocytes[2] and the variation in the thickness of glomerular capillary in freshwater and marine teleosts[3]. However, little is known on the microvasculature of the glomerulus of the teleostean species[4]. Paucity of information on glomerular vasculature forms the basis of the present communication on the angioarchitecture of the glomerulus of a swamp catfish, *Chaca chaca*.

Chaca chaca is a curious-looking catfish inhabiting the swamps of northern Bihar (India) infested with macrovegetation and decaying organic matters. This fish is well adapted to such hypoxic swamps. Live specimens of *C. chaca* were collected with the help of local fishermen from the swamps near Purnia (Northern Bihar, India) and transported to and maintained in the glass aquaria (40 l) of the department.

The fish (65 g) was anaesthetized in MS 222 (ethyl-m-aminobenzoate). The fish was carefully operated and its ventral aorta was cannulated via the exposed bulbus aorta. The entire vasculature was flushed with heparinized phosphate-buffered Ringers solution. Methyl methacrylate (Mercox) was infused at 25–30 mmHg pressure until the resin polymerized into plastic[5]. The mercox-perfused fish was immersed in warm (50°C) water for about 1 h to ensure complete polymerization. The fish was treated with 20% NaOH, distilled water and HNO_3 to obtain tissue-free vascular replica. A part of renal vascular replica was processed and examined under P SEM-500 at RSIC, Bose Institute, Calcutta.

From the corrosion vascular replica it is evident that the renal arteries of the two sides of kidney originate alternately from the dorsal aorta at an interval of about 0.93 mm. The renal artery runs away from the dorsal aorta transversely for about 233 μm and then turns at right angle, runs for about 700 μm to give rise to the glomerular artery (Figure 1). The glomerular artery connects the tortuous glomerular capillaries through AGA. The tortuous capillaries are perhaps associated with lowering the velocity of the blood flowing through the glomerulus for its effective renal functioning. In narrow capillaries (diameter about 7 μm) red cells flow in their centre in a single file. Such a flow pattern is designated as axial train type. In wider capillaries (diameter about

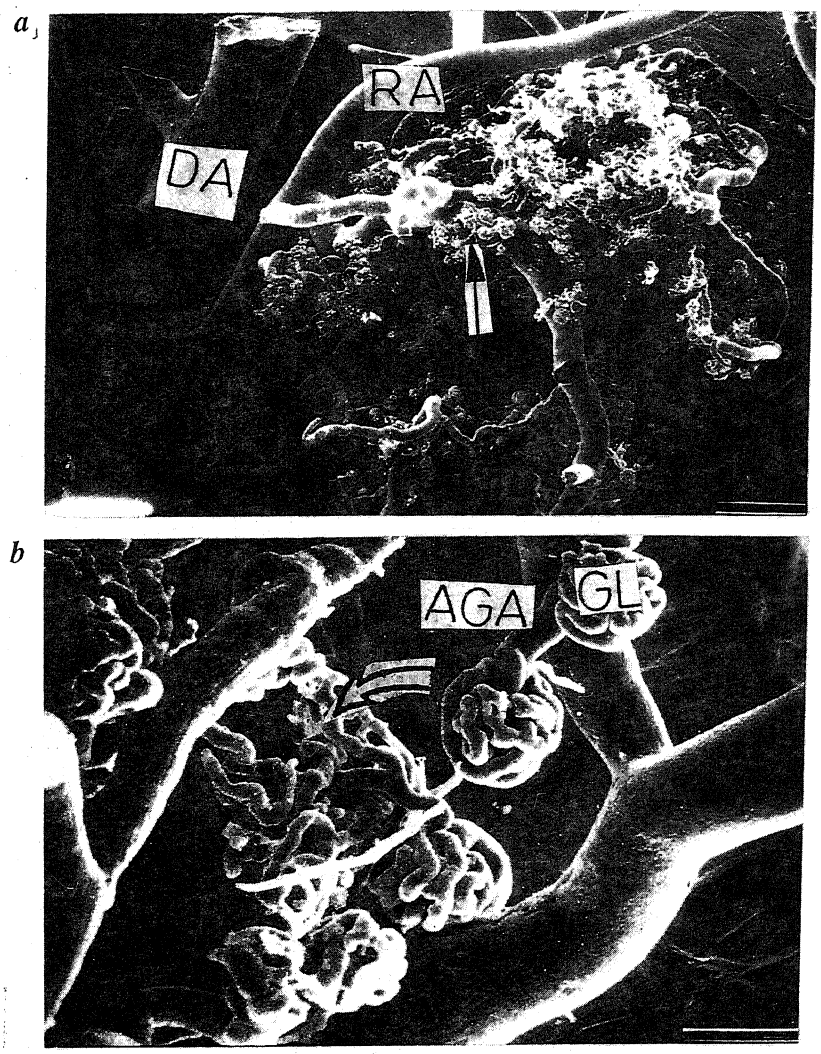

Figure 1. *a*, Corrosion vascular replica of a part of renal tissue showing dorsal aorta (DA), glomeruli (arrow), glomerular artery (arrowhead), and renal artery (RA), bar = 700 µm. *b*, Magnified view of above showing afferent and efferent glomerular arterioles (AGA, EGA), arteriovenous anastomoses (bent arrow), glomeruli (GL) and vein (V), bar = 50 µm.

11 µm) red cells flow in a multiple file. This type is referred to as shearing core type. When the capillary diameter varies between 8 and 10 µm, both types of flow patterns can occur[6]. Narrow capillaries (diameter 7.08 ± 1.2 µm) and the dimension of the short axis of red cells (5.6 µm) suggest[7] single axial file of erythrocytes flowing with peripheral plasma layer in the glomerular capillaries of *Chaca*. Like carp (*Cyprinus carpio*) and unlike marine fish[8], the AGA and EGA are of similar dimensions to ensure comparatively higher filtration rates at lower pressures in the glomerulus. To the contrary, wider AGA and narrow EGA of marine fish are associated with low filtration rates at higher pressures[8]. The EGA ramifies into arteriovenous anastomoses before its blood is drained into the renal vein.

Location and magnitude of the 1833 Nepal earthquake and its relation to the rupture zones of contiguous great Himalayan earthquakes

Roger Bilham

Accounts of an earthquake on 26 August 1833 which was felt over a large part of northern India have been interpreted by some authors to represent a great Himalayan thrust event beneath Western Nepal. However, details of the event in the Indian press of 1833 and scientific journals of that time suggest that the epicentre of the earthquake was near Kathmandu, within or close to the inferred rupture zone of the 1934 Bihar earthquake. Estimates of the moment magnitude based on reported intensities indicate that the earthquake was of $7.5 < M < 7.9$, and as such may have done little to release the elastic strain accumulating in the region of the Central Himalayan Seismic Gap, contrary to the expectation of some authors. The location of the epicentre was probably N or NE of Kathmandu, adjoining or overlapping the rupture area of the great 1934 Bihar/Nepal earthquake. The moment magnitudes of great Himalayan earthquakes in 1897, 1905, 1934 and 1950, and of smaller recent events, are compared using recently published empirical relations between isoseismal areas and moment magnitude. When due allowance is made for deficiencies in field data, reasonable fits are obtained for all events except for the 1905 Kangra earthquake. The intensity VIII area for this event is anomalously small for an $M \geq 8$ earthquake associated with several meters of slip. It is proposed that the Kangra earthquake may have been a slow earthquake.

APPROXIMATELY half of the Himalayan arc has ruptured in four great earthquakes in the past 100 years (Figure 1). The largest region between the rupture zones of these recent events is a 500–800 km segment of the Himalaya between the 1905 Kangra and the 1934 Bihar earthquakes, approximately between the longitudes of Kathmandu and Delhi. Of importance in estimating the present slip potential of this segment, termed the *Central Gap* by Khattri and Tyagi[1], is the existence and severity of great historic earthquakes that may have ruptured all or part of the gap. A severe earthquake occurred in Nepal in 1255 when 'innumerable towns were utterly destroyed and thousands of their inhabitants killed'[2] but the regional extent of this event is unknown. Other large pre-XX century earthquakes in Nepal (1408, 1681, 1810, 1833 and 1866) are mentioned by Chitrakar and Pandey[3] but none appear to have been as damaging as the 13th century event, causing concern that considerable elastic strain may be available presently to drive one or several $M > 8$ earthquakes in the Central Gap.

An alternative mechanism to absorb slip between Tibet and India is to invoke the possibility of aseismic slip (slow earthquakes or creep) over at least a part of the region. Levelling data and recent GPS measurements between India and central Nepal[4–6] suggest that creep processes that might otherwise release Indo-Asian convergence aseismically have been insignificant in the past few years. If similar creep rates (2.5 ± 2.5 mm/yr) exist elsewhere along the arc throughout the seismic cycle, they are evidently inadequate to accommodate completely the slip budget between India and southern Tibet, although they may delay rupture[7]. The possibility that some Himalayan earthquakes may be slow events, with large slip but little radiated high-frequency seismic energy, cannot be excluded[8,9]. Such events would not appear in the historical record as great earthquakes although they could, in principle, release the elastic strain associated with one.

Earthquakes in 1803, 1833 and 1866 appear to have occurred at least partly within the Central Gap[10] and the largest of these in terms of felt area is believed to be the 1833 event. Reports of the 1833 earthquake are found in newspapers starting the day after the earthquake, and these and other data are collated in three issues of the *Journal of the Asiatic Society of Bengal* in the months following the earthquake by Prinsep[11] and Campbell[2,12], and by Baird-Smith[13,14] in two articles a decade later. Summarises of these summaries are found subsequently in various catalogues and comparative studies[15–21]. The compilation by Dunbar *et al.*[21] lists the event as severe

Roger Bilham is at CIRES and the Dept. of Geol. Sci., University of Colorado, Boulder CO, 80309-0216, USA.

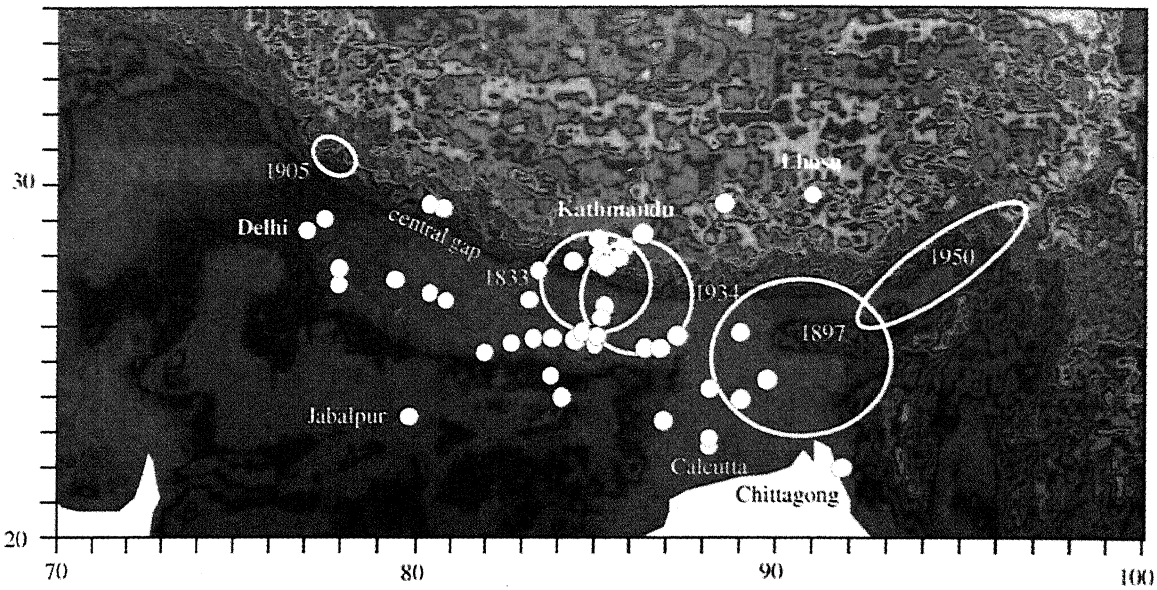

Figure 1. Approximate Modified Mercalli Intensity VIII zones for 4 great earthquakes in the Himalaya since 1833 and settlements reporting information concerning the 1833 shock (white dots). A great earthquake may not have occurred in the 800 km segment of the Himalaya between the 1905 Kangra and 1934 Bihar earthquakes (Central Gap) for 650 years.

and records its location as 25.1°N and 85.3°E, near Patna, south of the River Ganges, at the southern limit of intense shaking described in 1833 reports. A location west of Kathmandu is favoured by some authors[22], who suggest tentatively that it may have occurred in the Central Himalayan Gap. Khattri and Tyagi[1] place the earthquake approximately 130 km west of the Bihar 1934 epicentre on the edges of the Central Gap and assign the event $M = 7.6$, a location and magnitude consistent with the findings of the present study. One purpose of this article is to estimate more precisely the location and magnitude of the 1833 Nepal earthquake using authentic accounts found in newspapers and scientific articles published soon after its occurrence. A second purpose of the article is to reconcile the intensity data from the 1833 earthquake with the felt reports of four great Himalayan earthquakes and other earthquakes that have occurred since then.

The 1833 earthquake

Just before midnight on 26 August 1833 (23:35 Calcutta time), a 1 million km^2 region of northern India, Nepal and Tibet was shaken by a strong earthquake which triggered landslides and rockfalls, destroyed more than 4600 dwellings and many temples, but apparently resulted in fewer than 500 fatalities. It is certain that the loss of life would have been far more severe had not the main shock been preceded by two large foreshocks 5 h and 15 min before the main shock that drove people outdoors in alarm. In some villages in northern Nepal and southern Tibet, 30% or more houses were destroyed. Damage in India was less severe with fewer than 10 reported fatalities and few buildings totally destroyed.

The main shock was felt from Delhi to Chittagong (Figure 1). It was not felt in Lhasa, nor are there reports of the shock further SSW than Jabalpur. Intensities were high in the mountainous region near and north of Kathmandu, and reduced rapidly to the south and more slowly to the east and west. Intensities remain high at the northern limit of high-intensity observations in southern Tibet. Accounts of damage where shaking was most intense suggest a similar intensity distribution to that observed during the Bihar 1934 earthquake with the principal exception that accounts of liquefaction features in 1833 are rare. Passes to Tibet were blocked by landslides, and the Kamla River was dammed by a landslide that burst 4 days after the event flooding the village of Baldeah near the India/Nepal border (Bengal Hurkaru, 16 September 1833).

Isoseismal coverage and accuracy

The fidelity with which the Indian newspapers reported the effects of the 1833 earthquake can be gauged by the faithful reprinting of articles printed in one by another. More than a dozen newspapers and weekly and monthly journals were published in Calcutta (The *Reformer*, Calcutta, **3**, 141, Oct. 27, 1833) although not all of them reported the news of the event, and a few are no longer available. Newspapers in Delhi, Bombay, Meerut and Madras also contain accounts of the earthquake. In the 52 accounts in the Appendix, 97 towns and villages are mentioned. Most of these reports can be assigned Modified Mercalli Intensities V–IX with reasonable certainty. Few 'barely felt' reports are available and fewer 'not felt' reports (e.g. Nazirabad, Xigatse and Lhasa), and the general sparcity of intensity IV or smaller observations prevents reliable estimates of those areas that ex-

perienced the earthquake weakly. The absence of details of construction methods of the houses destroyed, or of those surviving, means that intensity estimates are not as reliable as those for the 1934 earthquake[19], and although it is likely that construction practices changed little between the two earthquakes, it is certain that urban dwelling units and civic buildings were less numerous in 1833. This may influence comparisons between the 1833 and 1934 earthquakes because for both the earthquakes several damage reports are from urban regions near factories or administrative centres. The Gangetic Plain except for the Kingdom of Oudh, south of western Nepal, was under British colonial rule in 1833 (ref. 23). However, reports from Oudh are available despite a significant cholera epidemic in Lucknow and Allahabad. With perhaps the single exception of data from Monghyr (Monger) most of the reports contributed to the Indian newspapers are in the form of personal accounts of the earthquake with no statistical descriptions of urban damage. Few fatalities are reported: three during the main shock at Chapra and one during an aftershock in Bhagalpur. In some accounts additional fatalities are implied although it is probable that the low loss of life was real, and is attributable to the second foreshock that evidently drew people into the safety of the open air fewer than 15 min before the mainshock.

In contrast to the anonymous accounts in the Indian newspapers, Archibald Campbell, an assistant surgeon to the British Residency in Kathmandu, in three contributions to the Asiatic Society of Bengal[2,11,12] compiled unofficial numerical damage and casualty data from the Kathmandu Valley, from travellers returning along the Kodari route from southern Tibet (passing through Dulka, the northern Nepalese border district of Dolakha), and from the official delegation returning from Lhasa through southern Tibet. He also mentions damage to forts along the southern trading route from India (Hetauda, Chisapani). Although he also obtained information from western and east-central Nepal, his sources of information from these regions are not cited and data from these regions may be less reliable. Thus, unlike data from N and NE Nepal, which mention specific towns and villages, his information from western Nepal refers to regional administrative areas: 'At Gorkha (75 km E of Kathmandu), only two houses were destroyed; at Palpa (180 km E of Kathmandu) none; and at Doti (540 km E of Kathmandu in easternmost Nepal), on the borders of Kumaon, the shock was felt, but by no means severely.' Although this westward decay in intensity over several hundred km is unsupported by details, it is consistent with the decay in intensity documented independently in northern India. For example, Baird-Smith[13] reports that 'it was scarcely felt at all' at Lohughat (=Lohu Ghar, 29°23′N, 80°05′E, 18 km from the E. Nepal border). Campbell[2,12] also emphasizes that the shock was not felt in Lhasa nor Xigatse, contrary to Mallet[16] and Dunn *et al.*[19], who repeat early speculation by Prinsep[11]. In a following issue, Prinsep, as editor of the Asiatic Society journal, corrected his erroneous guess that Lhasa was close to the epicentre[2,12] but not until it had been repeated in Calcutta newspapers[24].

In general terms, information concerning the 1833 earthquake in northern India is restricted to British trading posts, and information from Nepal and Tibet appears to be restricted to the Kathmandu Valley and to villages on merchant routes from Kathmandu to Tibet and to India (Figure 3 and Tables 1 and 2).

Location names

Place names in India are readily matched with current locations for all but three 1833 listed localities: Tirhoot, Mullye (Mallai of Prinsep[11]) and Baldeah. The first of these corresponds to the district of Tirhoot south of Nepal named after the town of that name, now Muzaffarpur (District Map of India, 1840, 64 mi = 1"); however, it is not clear that the three damage reports from Tirhoot came from Muzaffarpur or from villages between Muzaffarpur and the Nepal border (Motihari, Sitamarhi, Darbhanga, etc.). Despite the absence of specific locations, the high-intensity shaking reported from Tirhoot unquestionably identifies a region in the southern Terai of Nepal or northern plains of India.

Mullye has eluded identification with either a district or town, and in this case the absence of a precise match is regrettable because from this region comes one of the two comparisons of the 1833 event with the 1803 Kumaun earthquake (the other account from a resident in Calcutta recalling the occurrence of a severe earthquake during the siege of Aligarh (27°55′N, 78°10′E) soon after the start of the second Anglo/Maratta war). The approximate location of Mullye is revealed by the fact that Calcutta news reports from Mullye took 9–11 days between mailing and publication. An additional clue is that a summary of the effects of the event south of 26°N from a correspondent in Agra omits mention of Mullye, suggesting that it lies to the north of 26°N. Mallet[15], who in 1851 discusses the 1833 earthquake as the 1834 Nepal earthquake places 'Mallai?' on a travel time map of India (*ibid.*, Plate XVII) at approximately 22.9°N, 91.2°E (Maijdi); yet the inferred intensities are too high, and the reported sun-clock times of the main shock too early, for this location. He corrects the date to 1833 in his report[16] of 1854. A graph of news travel times to Calcutta (Figure 2) shows that an eastward location for Mullye could correspond to the Vedic district of Malla, approximately between Gorackpur and Chapra, but this term is unlikely to have been in common use in the 19th century. Of towns and trading centres in the region, Mullye is considered a possible abbreviation for Malihabad or Malloon[23] near Lucknow,

Manjhi (25°40′N, 84°30′E) near Chapra, or Murliganj (25°42′N, 86°59′E) near Purnia. Malihabad is evidently too far from Calcutta for normal 9 day news delivery, requiring travel times exceeding 120 km/day. Although the remaining suggested locations are at the correct range for news delays of 9–11 days, the phonetic resemblances are poor. In the absence of certain identification the three intensity V reports from Mullye are omitted from the isoseismal map.

It has not been possible to identify the precise location of Baldeah on the Kamla River, where a flash flood followed the breaching of a temporary lake dammed by an earthquake-triggered landslide. From the description (Appendix) it is likely that this was near the Nepal border, perhaps at Batia 27°15'N, 86°08'E.

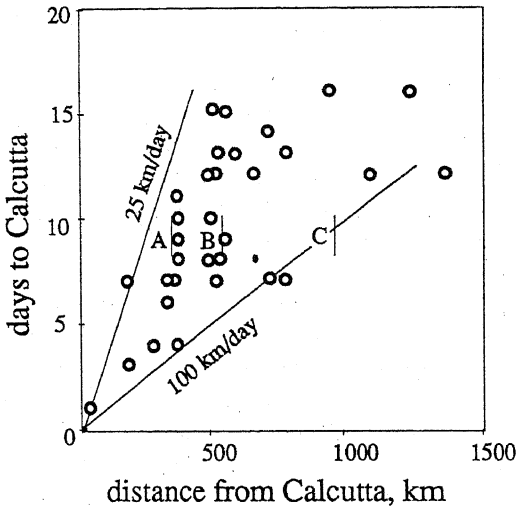

Figure 2. Delay between mailing a letter and its arrival in Calcutta assuming that publication occurs the day following its arrival. The three vertical lines indicate the possible locations for Mullye: A = Murliganj; B = Manjhi; C = Malihabad or Malloon. The Vedic district of Malla lies between B and C. Distances are geodesic. The most remote point on the graph from Calcutta is Delhi.

Place names with phonetic similarity and geographic proximity to the indicated regions have been identified for most of the villages in the Kathmandu Valley, and where these are questionable they have been identified in Table 1. Although relatively few locations outside the Kathmandu Valley are mentioned by Campbell, they are important in identifying shaking intensity to the north and east.

Campbell's latitude for Tingri (28°N) is approximately ≈ 60 km too far south, suggesting that he did not have good maps of southern Tibet. Rennell's 1782 Map of India (Figure 3), showing Tingri at 29.3°N, was known to be in error to the British Residency in Kathmandu in 1801 but new maps prepared by Crawford in 1803 of the route to Dugurcheh (Xigatze) were very incomplete[25]. Rennell's map is of interest because it shows Nesty, Dunna, Kansa, Chuska, Kut or Kutí, and Mescingzhung in sequence northward toward Tingri, over the mountain pass between Nepal and Tibet near the present border village of Kodari. The spacing of villages suggests that each interval represents a day's march. Nesty appears to correspond to Nisti, and the old fort at Dugunna Garhi may correspond to Dunna. Kansa is the village of Dram (Khasi in Tibet), 5 km NE and 400 m above Kodari, corresponding to Kassa mentioned by Campbell[12] without explicit damage reports. Chuska of Rennell's map may correspond to Choksum (28.07°E, 86.00°N) or Kan Sing Chok[2,12]. The location of Kuti mentioned several times by Campbell is the Tibetan name for Nyalam (D. Bresheares, personal communication 1994). At least two of the five villages mentioned as on the 'Bhote or eastern pass to Tibet' (Nan Sing Chock, Kuti, Kassa, Mundun Pahar and Listigaon) appear to correspond to villages in a 20 km NS region of intense shaking that includes the present border village of Kodari, and it appears possible that information from a region within a quarter of a degree of 27°N, 28°E was conveyed by travellers returning from Tingri to Kathmandu along this trading route.

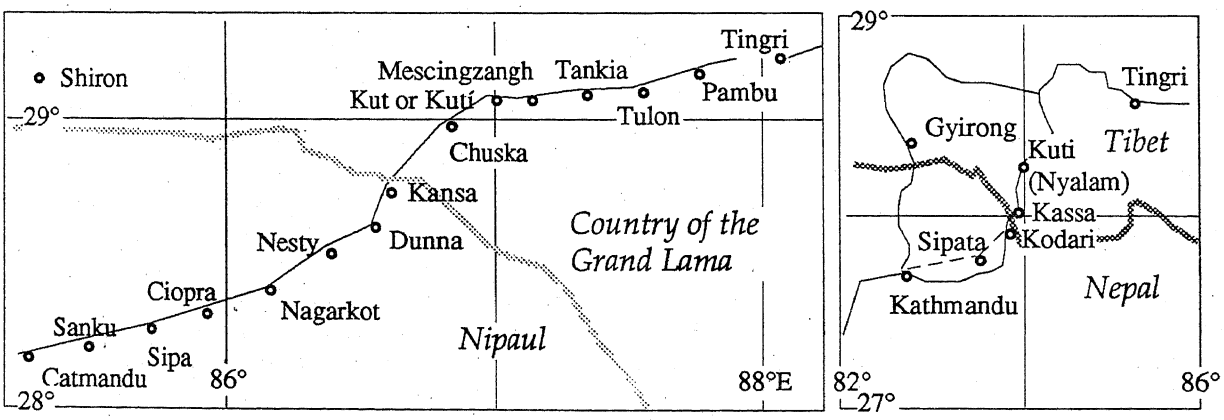

Figure 3. Villages between Kathmandu and Tingri through the Kuti Pass (Rennell's 1782 Map of India). Figure on the right shows the true coordinate locations for Kathmandu, Tingri, Gyirong, inferred locations for Kassa, Sipa, Kuti, and merchant routes to India and Tibet.

Rennell's map also shows the village of Sipa (Campbell's village of Shipa, 32 km E of Kathmandu) on the Kofs (Kosi) River between Sanku (Sankhu, 27°45′, 85°28′) and Ciopra (?Chautara). Sipa probably corresponds to Sipata or Sipatinghare (27°45′, 85°39′) on the Indrawatty tributary of the Sun Kosi, which lies on the trekking trail to Kodari north of the current Kathmandu–Kodari road. The village of Nagarkot (meaning Snake Hill) on Rennell's map between Ciopra and Nesty does not correspond to the geodetic observatory of that name on the eastern hills overlooking the Kathmandu valley.

The location of places in Campbell's account[2] are of particular importance in tracing the felt area to the north and east of Kathmandu. Digarchi is the present Shigatse or Xigatze (29°17′, 88°54′) and Tingri (28°30′, 86°30′) retains its old name. However, Campbell indicates that from Tingri a 8–10 day march due west brought the Nepal/Beijing returning delegation to the village of Kirung. Kyirong or Gyirong (28°33′, 85°16′, Shiron on Rennell's map) is 180 km W along the road from Tingri, and although the pass south of Kyirong enters Nepal by the Bhote Kosi, which means 'Tibet sacred river', it is only one of several rivers of that name crossing the border, including one through the Kuti pass into Kodari. It is for this reason that Campbell may have been misled into entering in parenthesis that the delegation came through 'the eastern pass of the valley into Bhote'. The Kyirong route they followed would more appropriately be called the northern pass to Tibet.

Isoseismal map for 1833

Descriptions from the original reports were assigned values on the Modified Mercalli Intensity scale (Tables 1 and 2 and Appendix). Where several reports from the same village exist, the intensity data in most cases agree, adding confidence to the observations. Moreover, although the intensity data for the 1833 event are somewhat uneven in coverage, they yield relatively smooth spatial variations in intensity (Figure 4). The intensity data may be interpreted as smooth curves that approximately encircle the appropriate intensity data, or more complex figures that adhere rigorously to mapped intensities. Figure 4 shows a series of smooth ellipses that approximate the observations. The resulting isoseismals are prejudiced by a preference for simplistic geometry; yet, though a number of alternative curves could be constructed, they would have the unavoidable characteristic of indicating maximum intensities in east-central Nepal, close to the 1934 epicentral region. A more realistic set of isoseismal curves is considered unwarranted given the distribution of intensity data. As an example of the complexity denied by adopting elliptic isoseismals, the intensity observations from the 1833 earthquake are superimposed on a map of the observed and inferred isoseismals for the 1934 Bihar earthquake. Few of the 1833 intensity data are found outside the corresponding 1934 isoseismals, suggesting that similar complexity in local isoseismal geometry may have prevailed in the two events, enforced by basin response characteristics.

An approximate estimate for the felt area of the 1833 earthquake (dashed on Figure 4) is found in Oldham's memoir on the 1897 earthquake[18]. Oldham does not indicate his sources although it is likely that the data came from his father's chronology of Indian earthquakes[12] and that the contour shown is meant to represent the area within which the earthquake was perceptible (i.e. Mercalli intensity II). This 0.21×10^6 km^2 felt area includes Chittagong to the southeast (editorial footnote by Prinsep[11] 'Mr. Walters informs me that it was also felt in Chittagong'), but omits information from Delhi and other western points, and from Jabalpur to the SW. The use of a smooth ellipse to embrace these western points increases the felt area to approximately 1.2×10^6 km^2. Uncertainty in this estimate is caused largely by the sparcity of data to the SW, E and N. Although the elliptical aspect ratio of the intensity $\geq$ VI isoseismals is favoured by the specific absence of felt shaking in Lhasa and Xigatse and by the shape of intensity VII isoseismals, the absence of reports from central India in theory permits the felt radius to increase substantially to the SW. Thus, the estimated areas for intensity $<$ V are assumed to err on the low side and estimates for earthquake magnitude presented below are given both for elliptical and circular isoseismals. Intensity I–III isoseismals are omitted from Figure 4 as no data are available. The largest ellipse drawn for the 1833 earthquake in Figure 4 corresponds to Mercalli Intensity IV, which is presumed to be significantly smaller than the area of felt perceptibility. Reports from locations specifying that the earthquake was not felt are absent except for the NE, and from remote locations such as Bombay and Madras.

Uncertainties in isoseismal area in Table 3 correspond to maximum and minimum estimates for areas contained within the smooth symmetrical contours selected to fit the observations in Figure 4. Although these are apparently uncertain to ±1% based on the mapped isoseismal reports, this figure does not account for errors in estimating the Mercalli Intensity from the eyewitness accounts reported in the Appendix. Variations in building toughness and subjective interpretation of damage may result in errors perhaps an order of magnitude larger. Moreover, from the 1934 (ref. 19) and 1988 (ref. 26) Bihar/Nepal events it is clear that isoseismal contours in the region are typically more complex.

The congruence between the 1833 and the 1934 intensity data is interesting in that in the few locations where isoseismic intensities disagree they differ by not

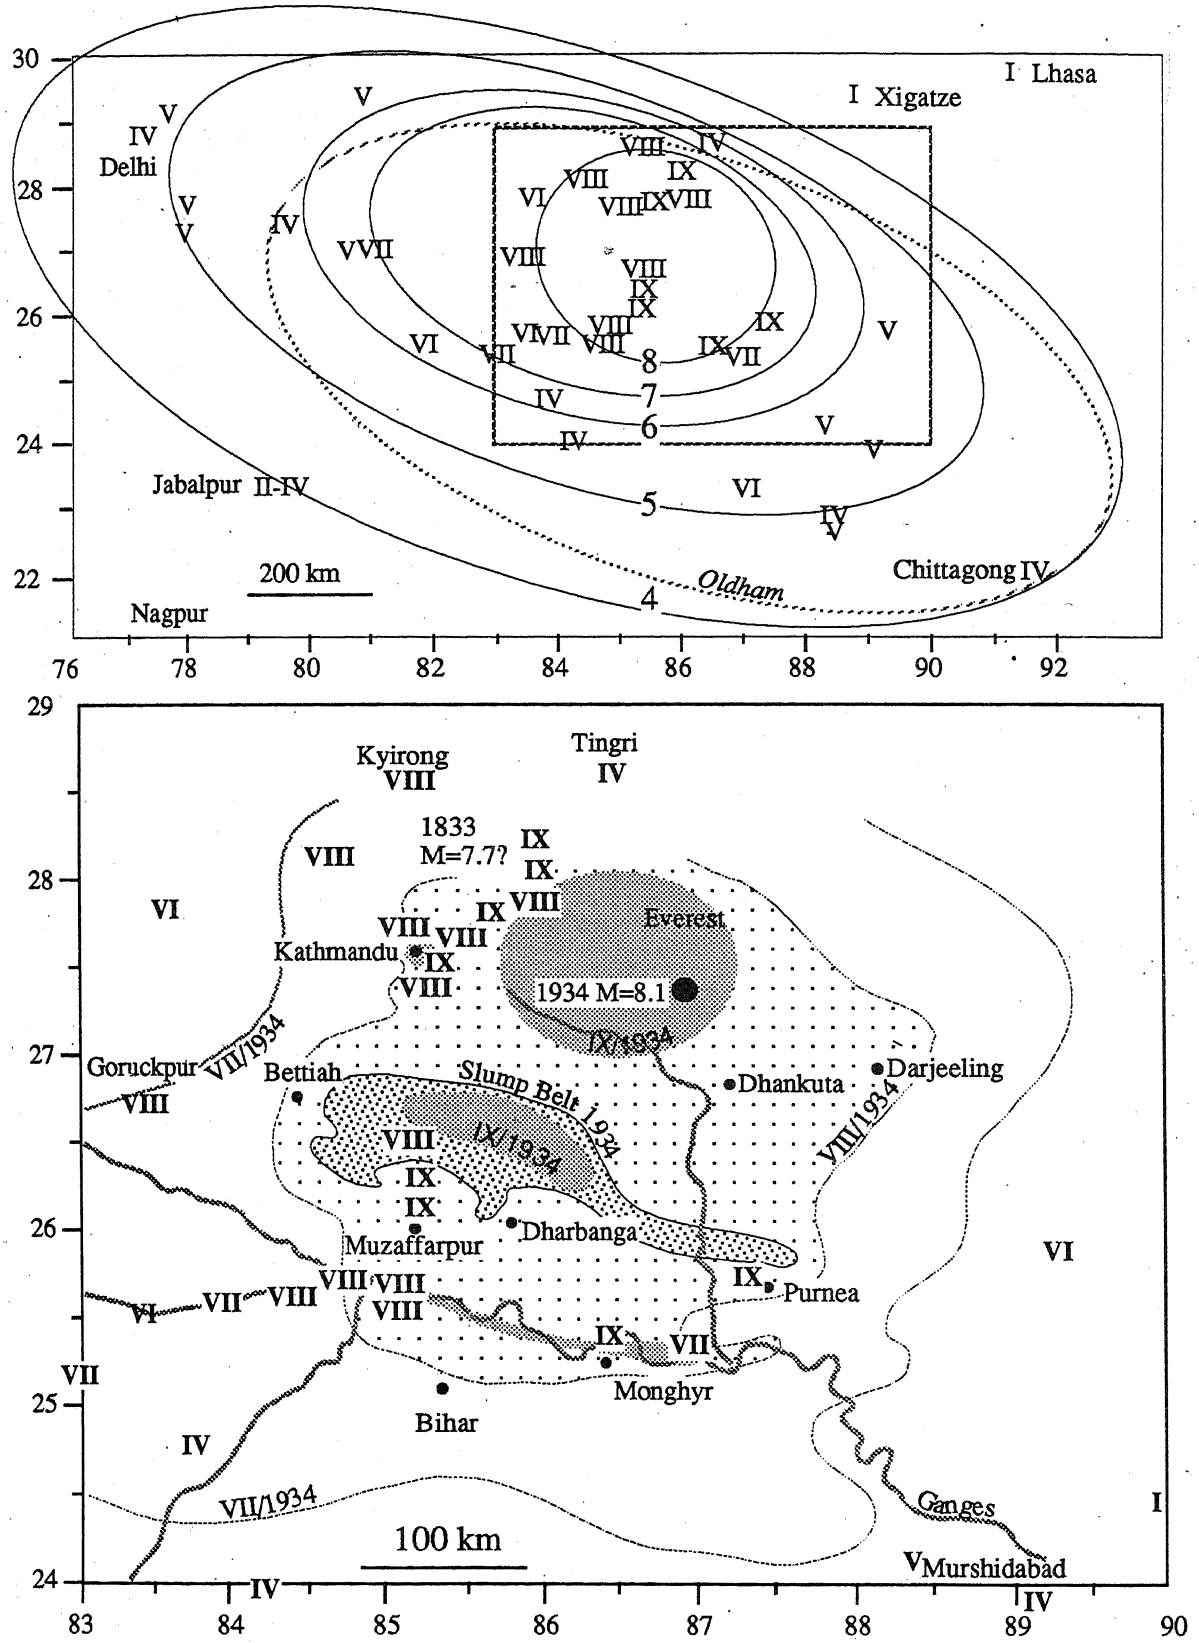

Figure 4. Intensity reports for the 1833 Nepal earthquake with smooth elliptical isoseismals. In the enlarged view of the epicentral region (inset above) the 1833 intensities are superimposed on isoseismals VII–IX for the Bihar 1934 earthquake (modified from Dunn *et al.*[19] by incorporating the data discussed by Pandey and Molnar[27]. On both occasions high-intensity shaking occurred in the same geographic settings although the 1934 isoseismals appear displaced approximately 100 km to the east. A possible 1833 epicentral location and moment magnitude is indicated.

Table 1. Summary of damage in Nepal and Tibet[2,11,12]. 414 fatalities, 172 injuries and 4040 destroyed buildings are estimated in the Kathmandu valley with additional fatalities and damage in villages to N and E

Named location	Modern equivalent	MM intensity	E. decimal longitude	N. decimal latitude	Houses destroyed	Notes

more than one intensity unit. The 1934 isoseismals shown in Figure 4 are somewhat uncertain within Nepal since they are formed by merging the isoseismals shown in Dunn *et al.*[19] with the intensity data discussed by Pandey and Molnar[27]. Although the resulting extension of the intensity > VIII data northward can be justified using the authority of Rana[28], the position and dimensions of the intensity IX region are conjectural. The centroid of intensity VIII area for the 1833 earthquake is apparently displaced approximately 1° to the west of the equivalent region for the 1934 earthquake, consistent with Khattri's 1987 location. This observation is sustained, however, by three observations only: at Goruckpur, Gorkha and at Chapra (Chuprah) on the Ganges. Examination of the first two of these reports shows that intensity VIII data are but weakly supported by the reports. Thus, were the buildings damaged of poor construction, a lower intensity could be assigned to these villages. The 1833 Chapra account describes slumping ('a chasm of considerable depth formed'), which may indicate a localized region of high-intensity shaking near the Ganges similar to the narrow intensity IX region in 1934. The inclusion of these westernmost VIII intensities in an elliptical fit to this isoseismal results in an 1833 intensity VIII area similar to the inferred 1934 intensity VIII isoseismal. However, a much smaller region for 1833 intensity VIII is admitted by the data if the same pattern of localized severe shaking occurred as in 1934. For example, the sparcity of intensity VIII data in 1833 between Dhankuta and Darbhanga admits the possibility that the area of intensity VIII shaking could be as low as 60,000 km^2 or as high as 100,000 km^2, the latter being the inferred area of intensity VIII shaking in 1934.

Three regions of severe damage were reported in the 1833 and 1934 earthquakes, an observation that led Dunn *et al.*[19] to note a similarity between the two events: the Kathmandu Valley, a high-intensity region near the Ganges, including Monghyr, and a region north of Muzaffarpur. Data for region near the slump belt of 1934, a region of catastrophic lateral spreading, are sparse and although high intensities are recorded near Tirhoot and Purnea (VIII–IX) no liquefaction features are mentioned here in 1833. The area consists of flat-lying sediments and ox-bow lakes across which numerous rivers meander. Further south, at Chapra and Monghyr, accounts indicate localized liquefaction near the Ganges, and minor ground damage is reported to the north, near Bhagmati in the Kathmandu Valley. Shaking intensities in the Kathmandu valley were similar for both the earthquakes, with highest intensities near Patan. Baird-Smith[13] noted that damaging shaking at Monghyr frequently accompanies large earthquakes, an observation repeated by both Dunn *et al.*[19] and Pandey and Molnar[27]. A favoured explanation for localized high intensities in this region is that surface waves are amplified in the water-saturated sediments as they approach the southward shelving bedrock surface south of the Gangetic Plain[27]. Similarly, the lake deposits of the Kathmandu valley can be assumed to be responsible for localized high intensities and rapid variations in intensity in this region as were observed most recently in 1988 (ref. 29).

Magnitude of the 1833 earthquake

Various empirical relations have been developed to relate felt areas to magnitude[30–32]. A physical formulation to account for the observed relation between intensity and moment magnitude has been proposed by Frankel[33] the coefficients of which have been fit to the global database by Johnston[34]. I shall refer to this as the F94 model. Moment magnitude, *Mo*, of an earthquake in the F94 model is related to the area enclosed within a specified isoseismal intensity contour, *S*, with an expression of the form

$$\log Mo = a + b \log S + c\sqrt{S}, \quad (1)$$

Table 2. Summary of the 1833 intensity data from Indian newspapers (see Appendix) compared to the 1934 Bihar earthquake intensity data from Dunn *et al.*[19]

*Baird-Smith[13] citing McCleland, p. 1051 (note that due to misnumbering, a second p. 1051 occurs, and p. 1053–1056 appear thrice distinguished by * and † symbols).

where the constants a, b and c are determined empirically for each isoseismal area. Intensity magnitudes are shown in Table 3 using the coefficients derived from worldwide data that include six Indian events[34]. A mean magnitude determined for the 1833 earthquake in this way is 7.5 ± 0.3, close to the $M = 7.6$ adopted by Khattri and Tyagi[1]; however, a monotonic decrease in estimated magnitude with intensity is observed, presumably indicating systematic differences between the global coefficients and those appropriate for the 1833 event. Data for several Indian earthquakes are presented in Figure 5 to illustrate these possible biases. Notwithstanding the ensuing discussion, a cursory inspection of Figure 5 indicates that the 1833 earthquake must be greater than

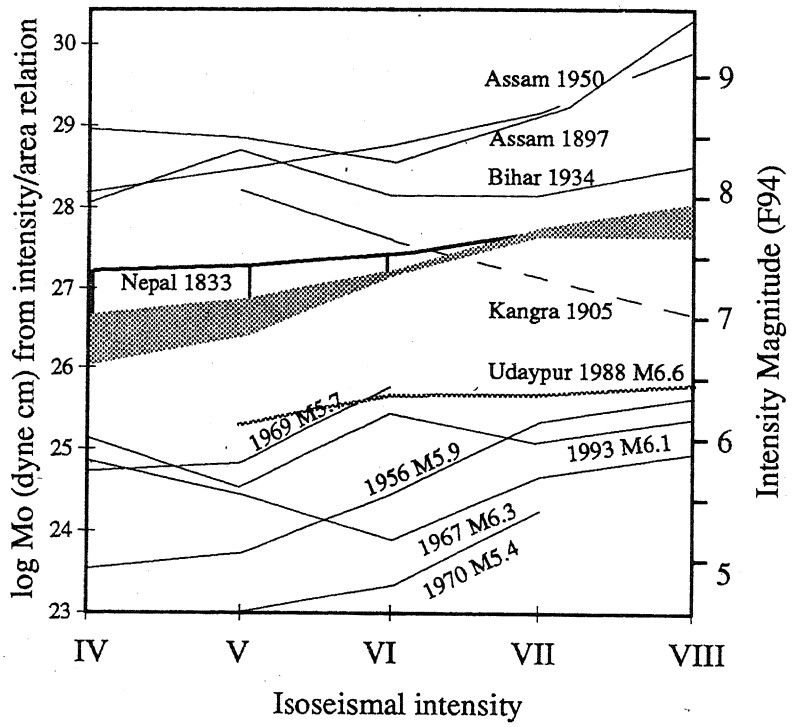

Figure 5. Moment magnitudes inferred from Johnston's F94 coefficients for several earthquakes in Nepal and India. The shaded area represents the range of magnitudes inferred for the 1833 earthquake using elliptical isoseismals (Figure 4). The overlying fenced region assumes circular isoseismals (see text). Assam 1897 data from Oldham[18], Bihar 1934 from Dunn *et al.*[19] and Pandey and Molnar[27], and Udaypur from 1988 data from Dikshit and Koirala[29] and Sinha[26]. Events in tilted script from Johnston[35].

Table 3. Isoseismal areas and estimated movement magnitudes for the 1833 earthquake. The constants *a*, *b* and *c* are from Johnston[35] for global data least-squares fit to equation (1). Moment magnitudes for elliptical areas (F94E) are from Figure 4, and those for circular areas (F94C) for diameters equal to the long axes of the ellipses in Figure 4 were unconstrained by data to the SE. Areas are expressed as $\log_{10}$(area km^2) and *Mo* in $\log_{10}$(dyne cm).

	Intensity felt	IV	V	VI	VII	VIII	Mean *Mo*
a	19.62	18.36	20.44	19.51	22.96	24.3	
b	0.5	0.903	0.607	1.307	0.628	0.352

Elliptical area (E)		6.16 ± .08	5.87 ± .06	5.55 ± .02	5.35 ± .02	5.02 ± .04	
log(*Mo*) F94E		26.4	26.7	27.2	27.8	28.0	
Mo F94E		6.9 ± 0.2	7.1 ± 0.1	7.46 ± .02	7.82 ± .03	7.9 ±0.3	7.5 ±.3
Circular area (C)		6.42	6.16	5.86			
Mo F94C		7.6	7.9	7.9			7.8 ± .2

$M = 6.6$ and less than $M = 8.1$, the inferred magnitudes of the Bihar 1934 and the Udaypur 1988 earthquakes.

Frankel[33] assumes that attenuation is radially symmetric, resulting in circular isoseismals. These are not appropriate for the Himalayan plate boundary. Yet it is not clear whether the observed isoseismal ellipticity is an artefact of reporting, an east–west amplification effect, or a north–south attenuation effect. The elliptical isoseismals inferred in Figure 4 have an approximate 2:1 aspect ratio with their long axes parallel to the Himalaya, but, as mentioned previously, this is possibly biased by the absence of reports to the north and to the SE. By assuming that the lower-intensity isoseismals approximate circles with their radii equal to the semi-major axis of the ellipses shown in Figure 4, circular intensity IV, V and VI isoseismals can be invoked that yield intensity magnitudes of 7.6, 7.9 and 7.9, respectively, raising the mean magnitude intensity to $M = 7.8$. Although the observations permit this interpretation towards the SE, the 'not felt' data from Lhasa and Xigatse[2,12] are inconsistent with circular isoseismals. Moreover, the elliptical aspect of Himalayan isoseismals

appears to be a common feature of Himalayan earthquakes. Intensity VI–VIII isoseismals for the $M = 6.6$ Udaypur 20 August 1988 earthquake exhibit an aspect ratio of approximately 4:1 (refs. 29, 36). Isoseismals VI–VIII for the 1991 Uttarkashi earthquake are elongated 2:1 along-arc[37] and intensity > VI and VII isoseismals for other Himalayan events show elongation parallel to the arc (e.g. Kangra VII 1905 and Bihar 1934). Thus, although the absence of radial symmetry for intensities > VIII could be ascribed to source geometry, it is surely necessary to invoke transmission effects as the reason for the elliptical isoseismal areas VI–VII found in the southern Himalaya and Gangetic Plain. For example, it is likely that the sediments overlying the stable continental crust in the Gangetic Plain act as a waveguide for surface waves travelling east–west with periods of 1–3 s (ref. 38). Similarly, the dipping interface between the Indian plate and the overlying sediments may result in less interference along strike than updip and downdip, favouring along-arc perceptibility. For the lower intensities that are felt south of the Gangetic Plain the intensity distributions for the four great earthquakes between 1897 and 1950 are approximately circular, consistent with transmission within a uniform crust.

Epicentre, aftershocks and rupture areas in 1833 and 1934

The location of the main shock cannot be determined unequivocally from the data presented here. This is largely because most of eastern Nepal and southern Tibet are unrepresented in the felt report data, preventing incontestable closure of isoseismals greater than VIII in these directions. A tantalizing intelligence attributed to 'vulgar report' by Campbell[12] is that for 5 days before the earthquake 'noises similar to the firing of cannons were heard as if underground: and in this neighbourhood' (Kan Sing Choke, possibly Choksum at 86°E, 28.07°N), 'the high road to Lhasa is said in many places to be blocked up by the fallen earth from the mountains'. If these are interpreted as foreshocks close to the epicentre of the main shock, the epicentre would be placed unreasonably close to a rapid decay in felt intensities eastward. That is, intensities at Tingri 100 km to the NE are estimated at IV, whereas at Kyirong and Kathmandu, similar distances from Choksum to the NW and SW, intensities exceed intensity VIII. Thus, if the main shock, or one of the foreshocks, occurred near Choksum, this may have been the eastward limit of subsurface rupture. The few aftershocks that were reported in 1833 do not provide any clear idea of the possible rupture zone of the earthquake southward or westward although their widespread manifestation favours a shallow thrust more than a deep focus event such as the 1988 Udaypur earthquake. Continuous ground motion in the days following the 1833 earthquake was claimed at Monghyr, Tirhoot and Kathmandu, the three regions of highest-intensity shaking. The concentration of felt aftershocks within these areas may not indicate the proximity of aftershocks to these locations, but instead may indicate either that the frequency of shaking in these locations was optimal for people to sense (e.g. 2–4 Hz, ref. 33) or that anxiety about further destruction heightened their awareness to aftershocks. On 4 October 1833, a strong aftershock was felt simultaneously at Kathmandu, Allahadad, Berhampore, Malda, Purneah and Bhagalpore, and another on 18 October at Goruckpore, Kathmandu and Allahabad. A surprising number of aftershocks were felt in the slump belt region in 1934 and the largest instrumentally located aftershock in 1934 is also found in this region[19].

Seeber and Armbruster[22] and Chander[39] propose that the 1934 earthquake ruptured a region forward of the main frontal thrusts of the Himalaya, at least as far south as the slump belt. High-intensity shaking was also observed near the Greater Himalaya and central Nepal close to the instrumentally determined epicentre, approximately 100 km north of the slump belt[27]. If it is assumed that the 1934 earthquake was $Mo = 8.1$, its rupture area could easily extend and embrace these two regions and extend an equivalent distance, or greater, along strike. However, the 1833 earthquake with a moment magnitude of 7.6–7.8 is unlikely to have ruptured an area more than 70 km on a side. The absence of catastrophic damage at the forts of Chisapani and Mukwanpur argues against a rupture zone centred at or near latitude 27°N, and it seems unlikely that rupture further south (beneath the plains) could generate >30% destruction in towns in southern Tibet. Thus, the rupture zone of the 1833 earthquake appears to have been centred in northern Nepal or southern Tibet, and unless it was a thrust of unusual aspect ratio, it would not extend beneath northern India. Thus, the inferred intensity VIII and IX shaking in the Gangetic Plain may have resulted from basin resonance, and not from the underthrusting invoked to have occurred during the 1934 event.

Following this line of reasoning, if a $M = 7.7$ 1833 earthquake near the Greater Himalaya could generate intense localized shaking in the Gangetic Plain, so too could the 1934 Bihar earthquake. Could the slump belt in 1934 be a product of basin resonance and prolonged shaking, thus not requiring slip to extend beneath the Gangetic Plain? Catastrophic lateral spreading occurred in the 1964 Alaska earthquake and was the result of vigorous and prolonged shaking of saturated sediments. It is not difficult to imagine that catastrophic lateral spreading could be confined to a region of especially intense shaking in 1934. The removal of the requirement for slip terminating near the slump belt would remove the obvious difficulty that there is no evidence for a

topographic bulge above the required southern edge of the inferred rupture. This was not revealed by levelling, nor is there any topographic evidence to suggest that the ruptures of previous shallow thrust earthquakes have terminated near the slump belt.

If it is assumed that the 1833 and 1934 earthquakes were both shallow thrusts, a limited number of geometries are possible if we require additionally that the two ruptures do not overlap. However, this requirement is not essential because the rate of development of available slip from Indian/Tibetan plate convergence is 1.5–2 m per century[40], and slip released in the 1833 event could have been effectively renewed by 1934. The simplest relation for the two events is that a region north of Kathmandu ruptured in 1833 and that a region roughly four times the area ruptured in 1934 immediately to the east. However, alternative and not necessarily more complex rupture geometries can be envisaged that would also be consistent with the available data.

Isoseismal areas and great Himalayan earthquakes

Were the worldwide coefficients determined by Johnston[35] for equation (1) appropriate to relate the felt areas of Indian earthquakes to their moment magnitudes, each event in Figure 5 would be represented by an horizontal line. However, intensity magnitudes determined for the four largest events show significant variance, indicating that the data for these events are unreliable, or that the Eurasian/Indian plate boundary requires adjusted coefficients in equation (1). Unfortunately, the intensity data for the four great earthquakes are both confusing and incomplete. They are confused partly because intensity scales developed for the industrial nations are not easily applied to the type of construction and destruction in each area, and partly because those responsible for the compilation of intensity data were unable to visit much of the afflicted areas to examine inconsistencies in written reports and hence apply uniform criteria to the observed damage. They are incomplete because isoseismal coverage is typically only for one-half of the shaken region. The data in Figure 5 have area uncertainties of up to 50%.

For all the four great earthquakes the maximum 'felt area' isoseismal reported in the standard works on these earthquakes[18, 19, 41, 42] yields moment magnitudes 1–2 magnitude units lower than the magnitude derived from the intensity IV isoseismal. Given that the intensity IV–VI isoseismals yield moment magnitudes consistent with those derived from radiated seismic energy, a possible conclusion is that the 'felt area' isoseismal has been significantly underestimated for these events. Surface wave dispersion results in progressively lower frequencies dominating the accelerations at increasing distances from the epicentre and distant accelerations are presumably shifted to frequencies that are not optimum for human perception. Distant 'felt' reports thus become increasingly 'instrument'-based: long-period oscillations in reservoirs, movements of chandeliers in churches, and slow movements of doors.

The 1897 isoseismals documented by Oldham[18] consist of precisely delineated regions of damage to masonry structures, and approximate areas assigned grouped Rossi–Forrel intensities. The low-intensity isoseismal areas are completed by extending Oldham's elliptic isoseismals to the north; however, the resulting areas may be uncertain by 50%. Isoseismal areas listed by Tandon[42], Poddar[43] and Ray[44] for the 1950 Assam earthquake yield systematically low moment magnitudes unless these are doubled to include the areas not visited to the north and east of the epicentre. This extrapolation is undertaken 'with the risk of great departure from the truth'[44], a truth already uncertain for the same reasons that the 1897 isoseismals are unreliable. Estimates of lower and upper bounds for these isoseimals result in more than a ±0.5 variation in assessed moment magnitude. Both the Assam earthquakes yield mean moment magnitudes between 8 and 9.

The 1934 Mercalli intensity data reported by Dunn *et al.*[19] yield reasonably consistent moment magnitude estimates although the values are somewhat higher than those derived by Johnston[35]. This is presumably because of uncertainties in closing intensity IV–VI isoseismals in southern Tibet. The intensity VIII area adjusted in Figure 4 to merge the felt data from north and central Nepal[27] with the data from Dunn *et al.*[19] yields a good approximation to the observed moment magnitude.

The Kangra isoseismal data as reported by Middlemiss[41] are unique among the four great Himalayan events in that they cannot easily be reconciled with the Johnston F94 coefficients. In particular, the mapped intensity VIII data are confined to two small regions, yielding an absurdly low estimate for moment magnitude ($M \approx 7$) compared with hitherto accepted magnitudes for the event ($M = 8.4$). This anomalously small area is evident in Figure 1. Yet the estimated intensity V isoseismal area for this event is consistent with an $M \geq 8$ earthquake. Even if the two mapped intensity VIII areas were to connect, which Middlemiss[41] is adamant they do not, or the Kangra intensity VIII isoseismal to bend southward, as suggested by Molnar[45], the increased area would bring the moment magnitude to no more than $M = 7.5$. A localized intensity VIII area associated with a large earthquake would normally be interpreted as being symptomatic of a shallow earthquake, or an earthquake in a region with abnormally high attenuation. Yet no surface rupture was reported there, and the widespread felt area indicates that the magnitude of the earthquake is typical of other great Himalayan events. The inversion of levelling data from the easternmost area is consistent with a slip on a shallow thrust of 7.5 m

(ref. 46), again consistent with the occurrence of a great earthquake. A possible explanation for a small high-intensity region and a large felt area is that the Kangra 1905 event was a slow earthquake. Slip on a shallow dipping buried thrust may have occurred at rates lower than the 1897, 1934 and 1950 earthquakes, insufficient to generate a widespread region of high accelerations but sufficient to stimulate long-period waves, resulting in a large felt area. In this interpretation, the high intensities observed near Kangra and Dehra Dun may have been associated with secondary shallow faulting in response to the underlying slip.

Conclusions

A 1 million km^2 of northern India was shaken by a significant earthquake in 1833 that appears to have been centred in north central Nepal. Although intensity X shaking occurred locally and more than 4000 buildings are reported destroyed, the loss of life (≈500) was small largely due to the occurrence of two large foreshocks hours and minutes, respectively, prior to the main shock. A possible location for the epicentre of the 1833 main shock is approximately 50 km north, or northeast of Kathmandu, although the limited number of observations in east central Nepal and southern Tibet permit an epicentre to the east of Kahthamandu, close to the epicentre of the 1934 Bihar earthquake. The 1833 earthquake resulted in damage intermediate in severity between the 1988 Udaypur $M = 6.6$ and 1934 Bihar $M = 8.1$ earthquakes. A mean moment magnitude of $Mo = 7.7 \pm 0.2$ is obtained by applying Johnston's F94 relation between isoseismal area and moment magnitude.

The inferred $M < 8$ magnitude and consequent relatively small rupture area of the 1833 earthquake indicates that it contributed insignificantly to reducing the potential slip in the Central Himalayan Seismic Gap between the Kangra 1905 and Bihar 1934 rupture zones. The slip associated with the event may have been 1–2 m, an amount consistent with a renewal time of 100 years. This and its proximity to the inferred rupture zone of the 1934 Bihar earthquake suggests that if the 1833 event occurred on a thrust fault, it may have ruptured a region abutting or overlapping the 1934 rupture. However, although remarkable similarities between the 1934 and 1833 isoseismal areas exist, the mechanism of the 1833 event is unknown.

The application of the F94 Johnston[35] algorithm to intermediate-intensity isoseismal areas of the four great earthquakes in the Himalaya yield moment magnitudes consistent with the currently accepted values. Maps for isoseismal intensities less than V and greater than VII are either less reliable or incomplete for each of these earthquakes. Even when generous allowance is made for the northward extension of the perceptible felt area, the intensity II area for the four events yields values that are too low by more than 1 magnitude unit, indicating that recalibration of the F94 algorithm for Indian earthquakes is desirable.

The 1905 Kangra earthquake is unique in that its intensity VIII felt area is anomalously small for a great earthquake. The seismically determined magnitude, the geodetically estimated slip, and the intensity IV–VI felt areas are consistent with an $8.5 > Mo > 8$ event, whereas the intensity VIII area is appropriate for an $Mo \approx 7$ event. A possible explanation for this anomalously small area of intensity >VIII shaking is that the earthquake occurred with a substantial slow component, and that the observed high intensities were associated with secondary ruptures near Kangra and Dehra Dun. The absence of broad-band seismic data for this and other Himalayan earthquakes makes such a conclusion tentative. However, if slow earthquakes do occur in the Himalaya they would have the benefit of absorbing plate convergence with less high-intensity shaking than normal high-frequency earthquakes. Moreover, if other $M \approx 7$ earthquakes in the historic record represent the secondary seismic manifestations of slow great earthquakes, the maturity of the Central Seismic Gap may not be as advanced as is currently believed.

APPENDIX

Accounts of 26 August 1833 Nepal earthquakes and aftershocks

Times in the original articles are converted to a 24-hour clock. Note that these original times are generally unreliable because they are expressed in local time usually set by a local sun clock and span a one-hour time zone. A precise astronomical clock was stopped in Calcutta by the second foreshock at 23:34′48″. The main shock occurred at approximately 23:54 and the first foreshock at 17:00. Mercalli Intensities are assigned to the main shock and to the five reports of aftershocks. The first line of each entry indicates the estimated Mercalli Intensity, where this can be determined.

Three reports from Nepal containing the observations of Campbell[2,12] are included in addition to an anonymous commentary from Agra.

Agra V

The Earthquake – Several shocks of an earthquake were felt in cantonments, as also in the city of Agra, on the night between the 26th and 27th instant. The shocks came in rapid succession, were strong, and lasted a few seconds each, but we have not heard that any accidents have happened.

(*The India Gazette, Calcutta, Tue., 12 Sept. 1833, III, 872, reprinted from the Mofussal Ukhbar, Aug. 31, 1833*)

Agra. The Earthquake.

The following account from a correspondent in Agra summarizes accounts in the above newspaper reports south of latitude 26°N, and adds a few locations not encountered in the primary articles that follow. It is included because it appears to be a systematic list of 1833 settlements from which news of the event was expected. It

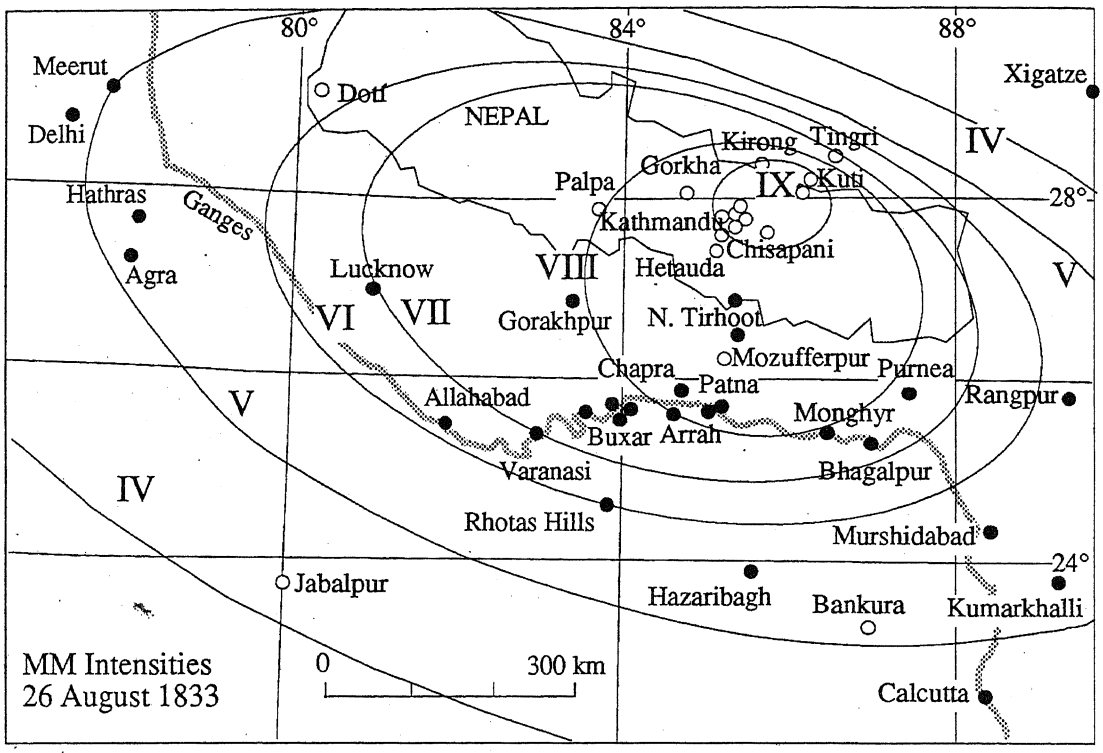

Figure 6. Locations reporting the 1833 earthquake. Solid circles from Indian newspapers and journal articles. Open circles from Campbell[2,12]. Location coordinates are listed in Tables 1 and 2.

claims to be the first of the two reports but a search for the second, which purports to describe damage north of 26°N has been unsuccessful. Mullye is not mentioned in this report, suggesting that it is located north of latitude 26°N.

We are happy to perceive a hint in the Calcutta Courier that the Secretary to the Asiatic Society is likely to favour the public with an account of the earthquake of August 26. To assist in rendering this as complete as possible, we have been induced at this early period to take a review of the information already collected for the purpose of showing what is yet wanted from individuals residing at places where the shock was sensibly felt. We would strongly recommend that a set of questions be circulated through the government by the Asiatic Society, as it is probable that there are many subjects connected with the sciences, besides the phenomena attending the earthquake, on which a light may be thrown by means of such an enquiry. We intend in the first place to confine our remarks to the sensible effects of the earthquake in different situations, and here we shall be obliged to recapitulate facts with which most of the readers are already familiar. The earthquake must have proceeded from a point or from an extended line or a space. The first subject, therefore, seems to be determination of these limits; in order to do this, we ought to possess properly an understood measure of intensity, so that we might ascertain our vicinity to the vortex or centre. Supposing that we assumed the earth to be of equal solidity throughout its surface, and that the earthquake had proceeded from a certain point, we should find a regular succession of accounts which would be exactly similar at similar distances. If the point, therefore, is ascertained, and any discrepancy appears in the accounts, we are obliged to refer this to the quality of the intervening strata. We may premise that there were three severe shocks; one at sunset, another at a little past 11, more severe, and the third one at or near midnight, the severest of all. Now did these three happen at the same place or at several places? If they happened at the same place, we should, by commencing with the accounts from the eastward remote from the epicentre, find exactly similar accounts to what we would have from the westward, and the difference of strata would have no avail, for having obtained three different degrees of intensity, they would all shade into obscurity (if we may be allowed to use the expression) in the same order at proportional distances.

22°N: We shall proceed from the southernmost point from which information has been obtained and take parallels of longitude from east to west. From the westward [this should be eastward?] of Calcutta no recounts have been received. At Calcutta and Dum Dum 2 shocks were felt, the first comparatively light one at 23:36, which stopped the astronomical and other clocks. The second one came on at 23:56, occasioning the doors to rattle while the punkhas, the wall shades, etc., were all thrown into violent agitation. It lasted about 1 min. This is all that has been recorded for this parallel, no accounts having been received from Midnapore, Singboom, Oodeypore, etc.

24°N: In 24°N latitude there are no accounts from Dacca – At Comercolly two shocks were felt, the first one at 23:45 lasting nearly a minute, the second one, somewhat lighter, about 10 min after. At Moorshedabad (=Berhampore), the first shock was felt at 19:00 but two others about midnight within 10 min of each other shook the house, awakened the birds, and caused the hanging lams to vibrate for 4 min afterwards. So severe was the shock that the writer feared his house would fall. The earth trembled so violently that it was with difficulty one could keep his footing.

At this interesting point, our information terminates, and we pass on to Hazareebad (Hazaribagh) on the southern side of the concussion. At this station the early shock at 19:00 was not felt; but one at 23:30 and a second one half an hour afterwards lasted 2 min, causing the punkha to swing and the door to rattle loudly. In a letter from the Rotas Hills, the first shock was felt at 23:10, a second rocking came soon afterwards, and at 23:11 it returned more severely, lasting not

less than 2–3 min; the roof of the house creaked, and the doors and windows rattled.

There are some discrepancies in this parallel which might perhaps have been explained had we possessed more extended accounts. For instance, the slightness of the last shock at Commercolly; secondly, the sudden increase at Moorshedabad. The slightness of the effects at Hazareebag, and the severity, considering the remoteness under the Rotas Hills we should presume that the situation of the last account must have been made considerably to the northward of Hazareebag.

25°N: We shall now take the parallel 25°N from whence the fullest statements have been obtained. From Sylkat we have no accounts, our first are from Rangpore, nearly in 25°N, where the shock was felt as at Moorshedabad. The first one took place at a little after sunset, slight and of short duration. The second one at 23:30 was strong, lasting about 30 s and the third one was still more severe, of 40 s duration.

No accounts have been received from Dinagapore, Malda or Raymahil (Rajmahal), and we are obliged to pass on to Poornea, where the shock produced still more severe effects. The first shock was felt at 17:00 slightly, the second one at 23:00 was severe and the third one at 23:18 was the most violent. The birds were driven from their nests; men were scarcely able to stand; cattle ran wild with fright; several old buildings in the town tottered to pieces; a part of one in the station sank partially; a heavy cornice fell, every building suffered more or less, and a recently vacated upper-roomed house had not an arch left. Large masses of bricks actually fell out of the walls. The roofs in many places split, and the beams and Burgahs separated an inch and more. The out-offices in the compound became a heap of ruins. The shocks are mentioned as occurring from 23:30 to 08:00. The last was somewhat severe; no mention is made of a subterranean sound.

Our next accounts are from Bhagalpore. The first shock was felt at 23:15, and a tremulous motion was felt for 3–4 min; at about 23:45 the third shock was felt when the chairs moved and the door rocked about; this lasted for about 8 min. Between this and daylight three other shocks were felt, but none equal to the first one; a rumbling noise was also heard, but not very loud.

From this we proceed to Monghyr. At this station the first shock occurred at 5 min after sunset accompanied by a rushing noise shaking like the movement of a steam engine. The second took place at 23:25, the third one at midnight, the fourth one at 02:00, and the fifth one at 03:45, etc. The second and third ones were most severe, causing considerable damage to houses, in which 34 were more or less injured by the falling of the balconies and balustrades, and by the cracking and separation of the walls and beams. The ground seemed to rise in waves about a foot in height. The lamps were all extinguished, making with the glasses on the sideboard, agitation of the jilmils and rumbling underground which accompanied the earthquake made a frightful noise. The first shock seemed to last for 30 s, and the second and third ones about 1 min each. Mr. H. and Colonel B., Mr. Pages and Captain Watson's houses sustained considerable damage. Large portions of the Rampart of the fort fell down. The shock was distinctly felt by the people in boats. Another slight shock occurred at 21:00 of the 27th. The Commissioner's house, situated at the highest point of the station, suffered the least, though the earthquake was severely felt there.

From Monghyr we proceed to Patna having received no accounts from Bar. The first shock was felt there at about 18:00, rather slight. The next one was felt when a number of houses fell and various sorts of injuries were sustained. Rajah Khan Bahadoor's stable fell, by which 7 of his horses were killed. Capt Elliot's house was also levelled with the ground. E. DeCosta's house cracked. At 23:30 says one, I was awakened by a horrid rattling and shocks, apparently from the east to the west with a rumbling noise, the servants running into room in great consternation. The last shock occurred at midnight, which was the most severe. At Bankepor (=Bankipore), 6 miles from Patna, houses were cracked, amongst which were the magistrate's Kutchery, and in the city the opium godown shared the same fate as also [the] gateway built by Maha Rajah Mohur Jay Singh, while many pucka dwellings had entirely fallen. Eighteen shocks were felt afterwards but they appeared continuous; the last one was at 08:00. At Dinapore (Danapur), 10 miles away from Patna, the former Brigade Major's house was split.

At Arrah, a little east of Dinapore, the first shock was not felt at 23:15, one occurred lasting a couple of seconds, the second one began about 10 min afterwards and was the most severe of the two. It commenced by a slight tremulous motion which gradually increased to the most terrific undulations, and was accompanied by a load rumbling noise, like thunder, underground. Doors, windows and every other article of furniture were thrown into a most violent agitation, several walls fell and some roofs were thrown off.

At Chuprah, in nearly the same longitude but a little to the north, the first shock at 17:00 was felt but slightly; at 23:00 another one came on accompanied by a tremendous rumbling, and a violent rocking of the house. At 23:15 the severest shock commenced with a tremulous motion, and a noise like thunder, followed immediately by a very long and awful agitation of the earth, which vibrated in a horizontal direction north and south. Slight shocks continued until 08:00 and a tremulous motion at intervals during the day. Large pieces of plaster fell from the walls in the rooms; native dwellings were destroyed; 2 miles from thence the earth opened; in consequence of the injury the court house sustained, the Cutchery was then held in a tent.

At Buxar, the force lessened – several smart shocks were felt, the first decided one took place at 23:20 but the smartest one occurred at 23:55. The motion was so strong as to upset several wall shades and glasses in one of the Bungalows there and the general rattling of the doors and windows and the creaking of rafters were really most alarming. The indigo factory was cracked, a rocking motion was felt by an officer in a budgerow; 5 miles above Buxar at Koorantadhee immediately opposite Buxar, it was so slight as to scarce waken a single individual.

At Gazeepore, the first shock felt was at 23:00 and the second one at an interval of 40 min. The first one was slight, the second as it were 4 or 5 successive undulations accompanied by a subterranean noise, heard however by very few. The cots of the soldiers were violently agitated so as to cause the occupants to start from their sleep, the walls and joints cracking.

At Benares, the first shock at 18:00 was not felt; at 23:00 a shock took place which continued for 4–5 s. This was succeeded by another one not very violent for 4 or 5 s; a more severe one was felt afterwards which lasted 2.5 or 3 min and the earth ceased to shake gradually.

At Allahabad, only two shocks were felt; 23:30 the same phenomenon presented itself with a more striking character, the short but quick vibration continued for nearly 2 min, accompanied with noise from the doors, windows, etc., and a dreadful hollow sound from the river.

We wish we could have completed this with a report from Culinger.

Having now finished an account of our principal parallel, we shall proceed to draw the inferences from the limited facts which have been collected. Rungpur and Moorshedabad appear equidistant from the centre. The former is equally far from Purneah as Moorshedabad is from Monghyr while at the latter two stations, the shock appears to have produced equally severe effects. At Bauglepore, although very near to Monghyr the effects are wonderfully lessened, leading one to the idea that the ground under Bauglepore was in no way connected with the earthquake, that it was more solid, etc., and therefore that the tremor lasted longer. A sound was heard at Bauglepore, Monghyr and less so at Purnea. The rumbling of stones, the rush, as it were of water, and of a mighty wind, are accompaniments of earthquakes which will probably lead eventually to the discovery of their cause. The appearance around Monghyr as well as the hot springs there testify to the volcanic nature of the subjacent strata.

At Patna the effect seems still nearly as severe, apparently diminishing towards Arrah. Our previous accounts from Hazareebag indicate that the effects decrease southward, while those from Purneah on the one side and Chuprah on the other indicate the boundaries east and west showing also severity in the latter case, that the ... effects of the earthquake are to be... in a northern direction from these stations. We observe the gradual diminution of the effects... Arrah until we come to Allahabad and may almost conclude that the last shock was just perceptible at Calinger.

By comparing Moorshedabad and Rungpore, we find them equal, and by comparing in the same manner Allahabad and Calcutta we shall also find that the effects are similarly described and that they are at equal distance, respectively, from Patna and Monghyr. The facts then lead to the conclusion that a given concussion produces similar effects throughout the earth's surface at equal distances. Should such be the case, and our information here be accurate, we should with these data be able to solve the following quotation: *Given the effects of an earthquake at two known points, and also the direction required* (missing words in the printed version of this statement), *the point from whence the concussion arose...* With this idea we have measured the distance between Calinger and Patna, and assuming that at Agra the effects were similarly felt as at Calcutta, we have put one leg of the compasses on the map at Agra and swept a circle which passes through Gazeepore, Guruckpore up the course of the Gandack to its origin in the snowy mountains.

Now we have already had an account of ... so that the effects of the earthquake must according to our data have been more northerly. It was, however, felt at Delhi, in a similar manner, and if we take the same radius we shall still keep to the source on the Gandack, from which we have not as yet obtained any accounts. We shall reserve another parallel for our next number.

(*Reprinted from Mofussul Akbar, 21 Sep. 1833.*In *The Bombay Courier*, **476**, 8 Oct. 1833)

Allahabad, 26 August **VI**

At Allahabad we regret to hear that death has lately been truly alarming and frequent in its occurrence [cholera epidemic]. We are also informed that two smart shocks of an earthquake were felt there during the night of the 26th. Our informant, who resides at the fort, states that he was awoken from a sound sleep at 23:00 in consequence of the tremulous motion being communicated to him by the bedstead – at 23:30 the phenomenon presented itself again with a more striking character; the short but quick vibrations sensibly continued for nearly 2 min accompanied with a noise from doors, windows, etc., and a dreadfully hollow sound from the river.

(*Reprinted from the Calcutta Courier in the Bengal Hurkaru and Chronicle XII(58), New series, Thu., 5 Sept. 1833*)

Allahabad, 16 Sept. **VI**

August 26. First shock 5 min before sunset, not severe; close, hot, light airs from NE; barometer 29.273. At 04:26, barom. 29.213. On the 25th same hour 29.253; thermometer 88°F on both days. About 11 PM and 11:30 very severe shocks were felt; loud noise, resembling distant thunder was heard. The river Jumna was thrown with violence against the banks. Many persons left their houses, both Europeans and natives.

(*The India Gazette, Calcutta, 24 Sept. 1833, II, 882*)

Arrah, 27 Aug. **VII**

Last night the inhabitants of this town were thrown into a state of alarm by two severe shocks of earthquakes. The first one took place at 11:15 and lasted for about 10 s. The second one began in about 10 min and was the most severe of the two. It commenced with a slight tremulous motion which gradually increased to the most tremendous undulations, and was accompanied by a loud rumbling noise, like thunder, underground. It appeared to proceed from north to south. Doors, windows and every article of furniture were thrown into the most violent agitation: several walls fell and some roofs were thrown off. All rushed to the streets and the whole town was in a state of commotion. We understand that some of the *sahib log* abandoning their beds ran into the streets in great consternation.

(*Bengal Hurkaru and Chronicle XII(58), New series, Thu., 5 Sept. 1833, reprinted from the India Gazette Calcutta, Wednesday, 4 Sept. III, 865*)

Benares, Aug. 27 (now Varanasi) **VII**

An earthquake happened here on the 26th instant, the particulars of which are as under. About 23:00 26 Aug. a shock was felt which continued for 5–6 s. This was followed by another, though not very violent, of 7 or 8 s duration. On going out to the verandah I found several of my friends and the domestics in a state of alarm. After a lapse of 5 or 6 min I returned to my chamber, but no sooner had I entered it, than a more severe violent shock was felt. This lasted 2.5 or 3 min and the earth ceased to shake gradually and imperceptibly.

(*The India Gazette, Calcutta, Wednesday, 4 Sept. 1833, III, 865, reprinted in Bengal Hurkaru and Chronicle XII(58), New series, Thu., 5 Sept. 1833*)

Benares **VII**

A native letter from Benares mentions that three shocks of an earthquake were felt at that station. It, however, appears to have most severely been experienced at Boglepore as detailed in a letter in the John Bull. The first shock was felt at 11:30, the undulations from the NW passing to the east. An hour after, a second shock was succeeded, more severe than the first, and afterwards six partial shocks ending at 2:30. The last one was accompanied by a sound resembling the rushing of a stream of water. A constant tremor of the ground was felt from 12 O'clock until daybreak.

(*The India Gazette, Calcutta, 26 Sept. 1833, III, 884*)

Berhampore, 4 Oct. 1833 aftershock

This morning, at a well known village called the Cuttereah, about 10 miles below Berhampore, while we were out for a walk we distinctly felt the shock of an earthquake. It came about 07:45 and lasted full 5 min; its direction was from north to south: the shock was slight but distinctly felt so that you see earthquakes are becoming more common now.

(*In Bengal Harkuru, Wed, 9 Oct., printed from Indian Register*)

Bhaugulpore, 27 Aug. 1833 **VII**

About a quarter past 11 last night, I was roused from my bed by a violent shaking of it, so much so that at first I thought someone was actually moving the bed about. I jumped out and saw the oil in the lamp moving about in tremulous motion which lasted about 3 or 4 min. I waited a little and got my wife and family on the verandah, when we plainly felt the chairs move and the doors rocking about. This lasted nearly 8 min, and between this and daylight three other shocks were felt, but none equal to the first one; a rumbling kind of noise was heard, but not very loud. In the year 1806 I felt an earthquake at Bencoolen as severe as this, but never before in this country.

(*The India Gazette, 1833, Tues., Sept. 3, III, 864*)

Subsequent commentary on above

Sir, The account contained in your paper relative to the late earthquake at Bhaugulpore is indeed terrific. The shock of 8 min duration must have been confined alone to your correspondents premises. His house must be evidently built of something more substantial than pucka materials, else how is it possible that it stood. Your correspondent adds that he felt the shock at Bencoolen in the year 1806 as severe. Judging from this, he must be an old stager; consequently, when age and fear act as existing agents, some allowances are admissible. I remain your obedient servant. – Anti Veteran.

(*The India Gazette, Calcutta, Wed., 18 Sept. 1833, III, 877*)

Bhaugulpore, 4 Oct., 08:10 aftershock

10 s of shaking described at length from the shock of the 4 Sept. 08:10. Birds disturbed. A mud hut about the neighbourhood had fallen, and an aged man, who could not get out in time, was buried under the ruins, and was taken out dead afterwards.

(*The India Gazette, Calcutta, Fri., 11 Oct. 1833, III, 897*)

Buldeeah – Inundation and Earthquake, 31 Aug. 1833 (possibly Batia, viz. Plate 12, ref. 47).

A letter from a correspondent at Buldeah dated the 31st ultimo states that the place had been visited by the most destructive inundation of the Kumlah river ever known. The river was increased by torrents from the Nipaul mountains so suddenly that hapless beings were drowned asleep in their houses at night. Cattle were swept off, and immense trees of the forest came rolling down the rapid stream that had undermined or cut away the banks on which they had flourished for many years in perfect safety. The earthquake of the 26th and 27th was also felt very powerfully at the same place.

(*The Bengal Harkuru and Chronicle XII(67), New Series, LXIV, 5768, Old Series, 16 September 1833*)

Buxar, 27 Aug. **VII**

Last night several very smart shocks of an earthquake were felt. The first decided one took place at 23:20, but the smartest of all at 23:55, each continuing for several minutes in a direction from north to south. The latter was so severe as to cause the members of all families resident here to run into the open air to secure themselves against the danger which seemed about to overwhelm them. The motion was so strong as to upset several wall shades and glasses in one of the bungalows here, and the general rattling of doors and windows, and the creaking of rafters were really most alarming.

The undulating motion of the ground was so great as to cause horses that were asleep to start up suddenly with the mark of alarm, and the birds roosted upon the trees to rise into the air, uttering wild cries.

Strange to say, the violence of the shock seemed a good deal bounded by the river, as at Koruntadhee, immediately opposite to Buxar, the motion of the earth was so little felt as hardly to awaken a single individual, whereas on the right bank of the river, all were obliged on the instant to evacuate their habitation and run into the open air.

The effect on the water about 56 miles above Buxar, as described by me, an officer luogoo'ed in his boat, was that of a rocking motion, as if occasioned by a heavy swell consequent on an east wind.

I am glad to be enabled to add that no serious injury occurred, unless one or two cracks in an Indigo factory bungalow, a few koss off, may be accounted as such. I have since heard that the shocks were most severely felt at Bhojepore, 15 miles distant in the east direction.

(*The India Gazette, Calcutta, Monday, Sept. 9 1833, III, 869*)

[Note: A kos is 3000 paces or approximately 2.3 km (p. 198 in Phillimore, R. H., Historical records of the Survey of India, Vol. II, 1800–1815, 477 pp.). The above account, though taken at face value by the commentator in *Mofussul Ukbar of 21 Sept. 1833*, and repeated by Mallet, 1852, is ridiculed in a reply in the Bengal Harkuru, Fri., 20 Sept. 1833, an extract of which is reproduced below.]

Dear Sir, We have all been a good deal amused here, with the account given in your paper of the 6th instant, of the earthquake at Buxar. 'It would certainly be important if true' – but there's the rub! Why! Mr Editor, your ordinary discrimination must surely have been in abeyance when you admitted so bright an idea as that 'the effects of the shocks could even appear to be bounded by the river'.

The fact is that the motion of the earth was felt just as severely at Koruntdhee as at Buxar on the right bank of the river, with this small difference, that your gallant and philosophical correspondent having previously confined a considerable time in his boat going down the river, sacrificed a little too freely to the Jolly God, at a certain glorification party on the night in question ... Servants, syces, etc., rushed out with one accord in the greatest state of alarm. In short, it was impossible not to have felt it. Yours truly, VINDEX. Buxar, 13 Sept. 1833.

(*Bengal Harkuru, Fri., 20 Sept. 1833*)

Calcutta

Sir, The correspondents who have favoured you with accounts of the earthquake that was lately felt in various parts of Hindoostan state in vague terms the direction which the earthquake took in its progress. Do they mean to say that the direction was north and south or from north to south (for these expressions convey different ideas to the mind). If the latter, what means have they of ascertaining the fact? Your obedient servant, B.

(*The India Gazette, Calcutta, Tue., 12 Sept. 1833, III, 872*)

Calcutta **V**

Two shocks of an earthquake were felt on Monday night: the first one occurred as is shown by its stopping an astronomical clock precisely at that time 23:35, and was comparatively slight and of short duration: the second one was far the most violent we ever remember to have experienced – the doors rattled, as if shaken by a storm of wind, the bed in which we slept was heavily for more than a minute, from north to south, with a gentler undulation afterwards in an easterly and westerly direction: the punkahs, the wall shades, the tables and chairs were violently agitated; and this second shock endured we should think altogether, for upwards of 2 min. It came on at about 23:56. The natives felt it in their huts and blew their horns as usual, and the crows and adjutants were disturbed by it and made a great noise, flying off from the houses and trees where they had taken roost.

(*Bengal Harkuru and Chronicle, XII(51), New Series, Wed., 28 Aug. 1833*)

Calcutta, 27 Aug. 1833 **V**

A slight shock of an earthquake was felt in Calcutta last night (Monday) at about 11:35. A stronger shock was felt at exactly 23:57.

Subsequent commentary on the above

Sir, you must be a sound sleeper from your editorial of this morning about a slight shock of an earthquake felt last night. I have witnessed many; and, except for that experienced in Lord Lake's camp on the night preceding the storm of Ally Ghur (note: 1 Sept. 1803, Kumaon earthquake). I remember nothing of the kind comparable to the lengthened rocking of my couch last night in the upper rooms of the Bengal club. I really expected to see the pillars of the verandah, if not the building itself, come down, and waited with tranquillity for my 'disruption of the visible world', not the oft recurring wish to behold what is beyond.

(*Cleophas. India Gazette, Calcutta, Wed., 28 Aug. 1833, III, 859*)

Chandernagore **VI**

The following is an extract of a letter from Chandernagore: 'In the night of the 26th–27th two shocks of an earthquake were felt in Chandernagore; the second one, much more violent, continued for about 3 min and commenced about half past 12 (*vers minuit et demi*). The attic of a house was thrown down, but no other accident occurred.' We suspect that our correspondent has mistaken the time of the last shock.

(*Bengal Harkaru, Thu., 29 Aug. 1833, XII, No. 52, New Series*)

Chuprah, 29 Aug. **VIII–IX**

In the night of the 26th instant we were thrown into great consternation by the most awful shocks of an earthquake, perhaps ever felt in this part of the world. The first was at about 5 O'clock in the evening and slightly felt. At midnight I was suddenly aroused from sleep by a tremendous rumbling noise and violent rocking of the house, which continued for some time. I remained in the verandah thinking that all was over, when in about a quarter of an hour another shock began, first with a tremulous motion and a noise like thunder, followed immediately by a very alarming and awful agitation of the earth, which vibrated dreadfully in a horizontal direction north and south.

We all rushed downstairs away from the house and continued in an open building until daylight, and as I did not sleep again, I observed that slight shocks continued till 8 in the morning; indeed, a slight agitation was felt at intervals throughout the day. Large pieces of the cornice and much of the plaster fell from the walls of the rooms.

All the people ran from their houses and several native dwellings were destroyed. I have since heard that three people were killed by the falling of their houses. As such severe shocks are unusual in this part, you will probably learn further accounts by the papers. Two miles from this the earth opened and a chasm of considerable depth formed. In consequence of the injury the Court house has sustained, Cutchery is now held in a tent.

(*The India Gazette, Calcutta, Fri., 6 Sept. 1833, III, 867, reprinted in Bengal Hurkaru, XII(60), Sat., 7 Sept. 1833*)

Comercolly (Khumarkhali, 23°52′, 89°11′) 27 Aug. 1833 **VI**

Two very smart shocks of an earthquake were felt here last night

(*The India Gazette, Tues., 3 Sept. 1833, III, 864*)

Delhi, 27 Aug. **V–VI**

An earthquake was experienced at Delhi at a quarter before 1 AM on the 27th instant which lasted 4.5–5 min; the shocks (by undulations) were rapid and distinct and their direction was from SE to NW.

(*Delhi Gazette, 31 Aug., first reprinted in the 11 Sept. issue of India Gazette 871 and again Wed., 18 Sept. 1833, III, 877*)

Futtigurh, Sept. 28 1833 **V**

Your 'excellent earthquake' was felt here very sensibly, I was sound asleep when it occurred, but the clattering of the doors and windows soon awoke me and made me leap out of bed. From the harmonious cawing of the crows and the sweet carolling of the minahs (?), I soon returned to my nest. A neighbouring house was much shaken.

We were subsequently visited by a meteor so brilliant that I was again woken from a sound sleep.

(*India Gazette, Calcutta, 10 Oct. 1833*)

Goruckpore, 27 Aug. 1833 **VII**

The first shock was felt at about 7 pm yesterday and was slight. At about 23:20 there was a severe shock, which lasted nearly 2 min; this shock awoke without exception, that I have heard, every European resident at the station, many of whom ran out of their houses, fearing that they would tumble about their ears, and really the shaking was so violent that it felt exactly as if the walls must be thrown down. After this shock passed away there was a continued vibration of the ground for about 20 min, at a few minutes before 12 another shock, much more violent and of longer continuance than the last mentioned, was felt, when open doors were slammed to, the jilmills rattled and the violence of the shaking was such that it seemed impossible for any fabric to stand it. The city was in an uproar, all the natives ran out into the street and continued out the remainder of the night. There was an almost constant vibration felt until nearly 6 O'clock this morning and three shocks, much less severe than the two between 11 and 12, at intervals between 12 and 6; since then all has been quiet. One or two houses in the town were shaken down but the only damage I have heard in the cantonments is the cracking in two places from top to bottom of the outer verandah wall of the civilians bungalows. It was a beautiful moonlit night without cloud or a breath of wind.

The shocks appeared to run from east to west – it was not an undulating motion such as I have at former occasions felt, but the sensation to a person in bed was more like what be felt if the bed were seized by several hands and shaken violently backwards and forwards. The natives here have scarcely recovered from the fears yet; they say they never experienced anything of the sort before, and it seems surprising that no houses were injured more materially, considering the violence with which they seemed to be shaken.

The river was exceedingly high and all the jeels and low ground with which it can communicate more extensively filled and flooded than they have been since the great flood in 1823, though the local rains have not been excessive; indeed, there has scarcely been an average fall and the weather has been delightful.

(*Bengal Hurkaru and Chronicle, XII(59), New Series, Mon., 6 Sept. 1833*)

Goruckpore (18 October aftershock) **VIII**

A correspondent writing from Goruckpore says that the station was visited on 18 Oct. 04:40 by 'a most tremendous earthquake' which came from east to west and lasted nearly 1 min. He adds that it was much severer than that which was experienced on the 26th last. It is singular that we felt nothing of the kind here, nor have heard anything of the earthquake from other quarters.

(*The India Gazette, Calcutta, Sat., 26 Oct. 1833, III, 910, reprinted from the Englishman*)

Hatrass (now Hathras) **V**

A considerable shock of an earthquake was felt at Hatrass. It appeared to last a minute and it seemed to be from NW to SE.

(*The India Gazette, Calcutta, Tue., 12 Sept. 1833, III, 872, reprinted from the Mofussal Ukhbar, 31 Aug. 1833*)

Jionpor 10 Oct. 1833 aftershock (Jaunpur) **V**

I lose no time in telling you of another earthquake, which was felt here yesterday at or about 8 in the morning; the shock was sudden and smart and lasted a few seconds. It shook all the jillmills and doors. Jionpor, 11 Oct. 1833.

(*The India Gazette, Calcutta, Sat., 26 Oct. 1833, III, 910*)

Kathmandu, Nepal, 27 Aug. **IX–X**

Have you ever experienced the sensation from the shock of an earthquake? If not, pray earnestly you may be spared a practical knowledge of this huge and incomprehensible phenomenon. Last evening about 18:00 we had in the residency grounds, and throughout the valley, a severe shock of an earthquake. I was in the house at the time. Doors, jillmills, chairs and tables commenced shaking most violently, then the house began to move, and when I got outside, the rumbling noise of cannon driving over a drawbridge was most distinctly audible, and gave the idea of vast bodies moving at full speed close to underground. The trees and shrubs moved from their roots with each undulation of the ground, and I could distinctly see my house reeling in unison with the trees around it. I pitched a tent to have a place of refuge against a repetition of the business. However, bed time came and we all save H. went to bed; but at 10:45 another and more violent shock than the first one obliged us to turn out, and as I rushed out of the house instantly, I had a noble view of the effects of this one. The ground moved in a long and even swell for about 30 or 40 s, and the doors and windows of our houses shook most vehemently. The whole people of the place set up a shout – the Hindoos called on Ranjee, and the faithful uttered long and deep prayers to God and his prophet – all were in confusion and amazement – when at 11:02 we heard the rumbling of a distant thunder and then a shaking and reeling of the ground that was quite fearful, accompanied by the noise of falling tiles, accompanied by a loud shout from the city which was quite audible here at a distance of a mile. I cannot tell you what were my own sensations on feeling the solid earth reel as a drunken man.

From this time till half past twelve we had six severe shocks and they continued until six in the morning. The residency is sadly injured – the whole of the upper story is nearly gone. R's house is rendered uninhabitable, and even mine, which is a pucka one of only one story, has got some awkward cracks in many parts of it. An elephant house, cook rooms and other small houses are much injured, and we want but a few more shocks to bring our houses down. No lives have been lost on the residency grounds, but it is otherwise at Catmandoo, Patna [*Patan/typo*] and other towns in the valley. The loss of life is not yet ascertained, but they say 25 in the former and 30 in the latter town. In both towns several houses have been levelled with the ground, and a large temple of Juggernauth, which had been formerly injured by lightning but was near an immense mass of pucka buildings, came down this morning by the run, and presents nought now by a mountain of bricks. The houses of many chiefs in the city have suffered much, and two pillars, each about 100 ft high, built by the minister and his nephew some years since, are now no more. The city is at present quite deserted, the Rajah having ordered every man to vacate his house and take to the fields for two days. Fair ones, who till last night had never seen the light of heaven, save through a purdah, were bundled *sans ceremonie* into the open air, and all in all it is a fearful state of things. I trust it is over for the present, but we are in doubts, for the last great earthquake here in 1829 continued for many days, and even at this sitting a slight shaking of the ground is perceptible.

Letters continue to arrive from all parts of the country especially from the north and west, giving accounts of the effects of the earthquake, some of which seem to have been of most serious character, involving destruction of life and property. It does not appear, however, as far as our information at present extends, that the calamity has been so heavy as was a similar visitation in 1829, while in comparison with the earthquake in 1762 it has been extremely mild and innocuous. On the last occasion the rivers and tanks throughout the country were strongly affected – the waters rushing with violence and rising in some places ten feet perpendicularly, and continuing in agitation for a quarter of an hour at a time. At Dacca 500 people were killed, at Chittagong the earth opened in many places, quantities of water gushed out, great chasms remained unclosed, reports underground were heard, and many buildings were thrown down. Near Luckipore, a circuit of land, about 15 miles in circumference, was swallowed up, and all the inhabitants and cattle perished. Nothing equal to this has occurred till now.

(*The India Gazette, Calcutta, Monday, 9 Sept. 1833, III, 869, reprinted from John Bull*)

Katmandoo, 30 Aug. **X**

On the 26th at 11 O'clock PM we had a serious shock of an earthquake, which is calculated to have destroyed 8000–10,000 houses and 600–800 souls in the several towns of the valley, and to have done extreme mischief beyond its limits eastward. The direction of the motion was NE and SW and its character, undulatory, with a very long swell and roll. The great shock was preceded, 5 h earlier, by a lesser one, and has been followed by innumerable trivial vibrations which have not yet ceased.

(*The India Gazette, Calcutta, Tue., 12 Sept. 1833, III, 872, reprinted from the Bengal Hurkaru Wed., 11 Sept. XII(63), New Series*)

Katmandoo, 30 Aug.

Further accounts have been received from Nepal describing the terrible effects of the Earthquake of August at Lassa, where the destruction of lives and buildings has been the greatest. The particulars, we understand, will be given in the *Journal of the Asiatic Society*. A late number of the *Mofussal Ukhbar* has a long article on the last earthquake in which reports are given for a great many places, showing pretty accurately the extent of its influences. The writer concurs with the author of the article in the *Journal of Science* in tracing the seat of the disturbing cause to some unknown spot among the Himalayan mountains. A fact is mentioned in the Chupra Report which merits the attention of our geologists if true, but which we should not hesitate to believe without further details, namely that the earth opened, and a chasm of some depth was formed about two miles from that place.

(*The India Gazette, Calcutta, Sat., 6 Oct. 1833, III, 892, reprinted from the Calcutta Courier*)

[Note: The J. Asiatic account is Prinsep's p. 438 in the August edition, and the Mofussal Ukhbar reference may refer to the 14 Sept. edition above that may contain more details than printed in the India Gazette. The comment about Chupra above refers to the entry in the 6 Sept. India gazette, III, 867, last paragraph on Chupra. Campbell is adamant that no damage occurred at Lhasa, and may have been prompted by the above news report to be emphatic about this in the November edition of J. Asiatic Soc.]

Lucknow, 27 Aug. **VII**

It may be interesting to your readers to learn that last night (the 26th instant) the city of Lucknow was visited by four shocks of an earthquake, the first about sunset, the others between 11 and 12 PM. The tremulous motion of two of the shocks resembled the motion felt in a steam vessel; the rocking caused the beams of the houses to creak, the lamps to swing to and fro, and in one house fragments of cornice to fall. In the stiliness of midnight, superadded to the knowledge that

the scourge of Cholera Morbus was now fearfully active throughout the city, there was something very awful in the sensation, and as the earth rocked and the walls moved, I almost expected to hear the crash of some falling building.

(The India Gazette, Calcutta, Tue., 12 Sept. 1833, III, 872, reprinted from the Mofussal Ukhbar, 31 Aug. 1833)

Lucknow **VII**

On the night of 26 Aug. an earthquake was felt here, some people felt several shocks, one about sunset. I felt only the last one, which must have been the most severe. It awakened all out of our sleep at half past eleven at night and lasted about 2 or 3 min. A servant of mine who thought the house was coming down ran across the compound to his own house, and fell down three times on the way, the ground shook so much.

(The India Gazette, Calcutta, Wed., 18 Sept. 1833, III, 877 and in Bengal Hurkaru, Fri., 20 Sept.)

Meerutt **V**

Earthquake. Meerutt was visited on the night of Friday last by the smart shock of an earthquake. It continued for about 15 s, but was not severe enough to do any mischief. We have received further accounts of damage done by the late earthquake in the country immediately above Benares. The tract lying between the Ganges and the hills seems to have been most severely visited; details have, however, been published in the Calcutta newspapers.

(The India Gazette, Calcutta, 10 Oct. 1833, III, 896 and in the Beng. Hurkaru and Chronicle Mon., 7 Oct. 5786, Old Series, reprinted from Meerutt Observer, 26 Sept.)

Malda, 4 Oct. 1833 aftershock **V**

We had a severe shock of earthquake yesterday at 08:10, which set the punkah swinging and venetians rattling in a fearful style. Malda, 5 Oct. 1833.

(The India Gazette, Calcutta, 10 Oct. 1833, III, 896)

Monghyr, 27 Aug. 1833 **VIII–IX**

Sir, Five shocks of an earthquake were experienced last night and this morning at this station. The first one occurred 5 min after sunset, the second one at 11:25, the third one at midnight, the fourth and the fifth ones at 03:45.

The second and the third ones were most severe and caused considerable damage to the houses in the town, of which about 34 were more or less injured by the falling of balustrade and balconies or cracking and separation of the sidewalls and beams.

Mr. Hamilton's house suffered severely, and the beams of the verandah all loosened from their sockets in the walls, and many feet of plaster cracked and torn off, the walls having been also much shattered.

At the third shock the inmates of my house all alit and passed the rest of the night in a temporary covering made with bamboos and a suttringee. The lamps were all extinguished by the trembling of the walls, the clocks stopped, and the glasses of the sideboard knocked together and made, with the agitation of the jhilmills and rumbling underground which accompanied the earthquake, a frightening noise.

The direction of the shocks appeared to take was from the NE to the SW. This circumstance was manifest from the noise made by the natives as the shock passed along. The people continued shouting and drumming the whole night, I suppose to propitiate the causes of this awful visitation.

I am unable to speak with any certainty of the duration of the shocks, but from what I have heard and from my own recollection, the first one appeared to last about 30 s, the second and the third ones about a minute each, after which there appeared to be a trembling motion in the earth for about half an hour, and the glasses in the sideboard continued during that time to shake.

Colonel Bird's house sustained considerable damage and his family was obliged to leave it altogether. They took refuge during the night in some tent pitched during the day to be aired.

Considerable portions of the ramparts of the fort fell down; I observed two places in my mornings ride to the extent of about 20 yards in breadth and 30 in height. These walls are made of brick and mortar cased with stone. I heard that there were two other parts of the wall that had been thrown down.

Mr. Page's house and Captain Watson's were also, I heard, much damaged. In my own the outer walls on the East and West sides cracked in several places, the fissures going quite through the walls.

There was no particular change in the river that I am aware of, but the shocks were distinctly felt by people in boats. One gentleman I met this morning said he thought at the time that a violent storm was coming on from the agitation of the water and the motion of the boat, but finding the true cause from the people on the shore he deemed it prudent to leave his boat.

So general was the consternation caused by this unusual event that nearly all the Europeans and other inhabitants of pucka houses resident in and about the fort left their domiciles and sought refuge in the maidan.

Yesterday was a particularly hot day, and the evening sultry and unpleasant. Today we have much the same kind of weather, but the horizon is surrounded by heavy lead-coloured clouds, and there is lightning in all directions.

Since the last shock above alluded to, partial and slight tremblings of the earth have been experienced the whole day.

The commissioner's house, situated on the highest spot at the station, did not suffer in the least; the earthquake, however, was severely felt there. Since writing the above another slight shock occurred at half past none P.M. Yours faithfully, A Resident.

(The India Gazette, Calcutta, Thur., 5 Sept. 1833, III, 866, reprinted in Bengal Hurkaru and Chronicle XII (59, New series), Mon., 9 Sept. 1833)

Monghyr, 27 Aug. **VII**

This station was visited by an awful calamity: a constant succession (about 30) of awful shocks from 17:00 yesterday until 08:30 today, of which some were so severe as to destroy several fine houses and materially injure others. The whole population of Monghyr spent the night in the open air, and we much feared that this place is the focus of volcanic matter, and that the present is but the forerunner of a still more severe visitation.

(Bengal Hurkaru and Chronicle XII(58) New series), Thu., 5 Sept. 1833, reprinted in The India Gazette, Calcutta, Fri., 6 Sept., III, 867)

Monghyr, 27 Aug. 1833 **VIII–IX**

We were last night visited by one of the most awful calamities that has ever been known in this place. A succession of seven shocks of earthquake from 17:00 till 08:30 this morning, in which many fine houses were injured and some totally destroyed; amongst the latter is Mr Graham's fine house, which was rented on a lease to Lt. Col. Bird. It was truly awful to hear the cries of the people and crash of houses falling, the ringing of bells, the beating of tom-toms, the Musselmans at prayers, and all the populations of Monghyr, of every description, out in the open air; the ground every 5 min shaking and trembling in a frightful manner. Mr B. and family were obliged to fly

for their lives, and come over to mine; several others did the same and amidst the horror and dismay of all around we spent the night. There were upwards of 25 shocks during the night, and 5 after day break.

(The India Gazette, Calcutta, Mon., 9 Sept. 1833, III, 869, reprinted from Bengal Hurkaru, XII(60), Sat., 7 Sept. 1833)

Monghyr

A letter from Monghyr mentions that shocks of earthquake were felt there up to the 29th ultimo and a letter from Mullye which we publish shows that they were felt there up to the 31st [August] inclusive. We are much obliged to correspondents who have favoured us with such accounts. They will doubtless be of use, as has been suggested, in preparing a connected statement of all the phenomena.

(The India Gazette, Calcutta, Wed., 11 Sept. 1833, III, 871)

Monghyr, 2 Sept.–Mon. 26 Aug. Earthquake **VIII**

Several pucka houses in the town sustained injury, and all are more or less cracked. I observe that the houses most damaged are those that have new buildings attached to the old – the same is the case with houses in the fort. I hear that all the clocks at the station stopped at the second, or severe shock.

(Calcutta Courier, 11 Sept., reprinted in Bombay Courier, XLI, 2277)

Monghyr, 12 Sept. 1833

You would no doubt be surprised at my last, how much more you will be astonished to learn that the earthquake mentioned in that has not entirely left us, we have had numerous shocks since the first one, but of no great magnitude, and perhaps they have added more fear than that to real injury, but certain it is that the earth has never been for even 5 min perfectly steady since the 26th of last month, and from the continued tremulous motion, many are fearful that it will end in some dreadful catastrophe.

(Bengal Hurkaru and Chronicle, Sat., 21 Sept.)

Morshedabad zilla, 30 Aug. 1833 **V**

We were visited on the 26th with several smart shocks of earthquake; the first one about 19:00 was but slight, but two others about midnight, within about 10 min of each other, shook the house, awakened the birds and caused the hanging lamps to vibrate for 20 min after – so severe was the last shock that I feared the house would be injured. The earth trembled so violently that it was difficult to keep one's leg. The natives in their frail tenements felt it severely for the neighbouring villages resound with their 'Hurribole, Hurribole'.

(Reprinted in Bengal Hurkaru and Chronicle, XII, 59 New Series, Mon., 6 Sept. 1833, from John Bull)

Mullye, 27 Aug. **V**

You will doubtless have numerous accounts of the earthquake which occurred last night at this station. The first shock, which was very slight, took place at 18:30. At 23:15 we had a very severe shock, and about 23:45 another one which continued whilst I deliberately counted 350, for I had no watch by me to time the shocks; some seconds must have also elapsed previous to my commencing counting. From this period until 03:15 we had a succession of slight shocks, in all 16 in number, and at 06:00 a seventeenth. They ran in a direction from north to south and the vibrations occasioned by the second and third were particularly violent, very nearly, if not quite as violent as the great earthquake in 1803. Meteorite at 3 am. Your obedient servant.

(The India Gazette, Calcutta, Fri., 6 Sept. 1833, III, 867, reprinted in Bengal Hurkaru, XII(60), Sat. 7 Sept. 1833)

Mullye, 30 Aug. 1833

Since the first night of repeated shocks at Mullye, we have experienced several slighter successions, on each succeeding day and night, up to this date.

(The India Gazette, Calcutta, 1833, Mon., 9 Sept. 1833, III, 869, reprinted from the Bengal Hurkaru. Tue. 10 Sept. 1833, XII(62), New Series)

Mullye, 1 Sept. 1833 **V**

I mentioned that we had no less than 17 shocks of earthquake at this station during the night of 26th up to 6 A.M. ultimo. In the course of that day two other slight ones occurred and two more from 9 to 10 P.M. On the 28th at 16:15 we had a very smart shock, the vibrations of which lasted for about a minute. On the 30th at 11:30 a slight one, at 01:00 this morning one shock, at 06:00 another shock. Numerous other tremors of the earth have been experienced, but we have become so accustomed to the sensation, that it is difficult to divest ourselves from the idea of the shaking, and it is only when assisted by the other senses, and that when we perceive the flapping of doors and moving of punkahs, etc., that we are satisfied we are not under a delusion.

(The India Gazette, Calcutta, Tue., 10 Sept. 1833, III, 870)

North Tirhoot (North of Muzaffarpur), 27 Aug. 1833 **VIII**

This part of Tirhoot was visited at 18:00 yesterday by a severe shock of an earthquake, which began with a motion from east to west and which was repeated at 11 and 12 with double violence continuing throughout the night until 6 this morning. The two shocks in the middle of the night were most awful, lasting I should think, each time, more than a minute. The bungalow in which I reside was violently shaken, rocking to and fro, the doors and wall shades were equally agitated, and the walls were rent in many places. Had the successions towards morning been equally violent, I fear my bungalow would have been in ruins.

The walls of my press house and drying house were opened in several parts and the water in the reservoir 4 ft deep and 3 ft from the surface was so much agitated as to fly over each side. At one time I thought all was going to rack and ruin.

I have been in India for many years, and I have never experienced anything half so awful as the shocks during the night. In 1818 [probably Cutch earthquake 1919] if I remember right, a severe shock was felt in Calcutta, but nothing equal to the one of last night.

(The India Gazette, Calcutta, Mon., 9 Sept. 1833, III, 869)

Nusseerabad (Nasirabad, 24°26′, 90°) **I**

'No mention is made of the earthquake.'

(The India Gazette, Calcutta, 26 Sept. 1833, III, 884)

Patna, 28 Aug. **VIII**

But now we have recovered from the horror of the event I have to communicate of an earthquake which has alarmed us exceedingly. Its first access was 18:30 on the evening of Monday, and I distinctly felt the shock, but as I was not supported by any observation of similar tendency, I began to think it must have been fancy. About 23:30 I

was awakened by a horrid rattling and shocks apparently from east to west with a rumbling noise, the servants running into the room in great consternation, when the whole truth flashed upon my mind. This was the first of two very severe shocks, the last of which occurred at midnight, and the oldest inhabitants here say that a severer one they never remembered. It is quite impossible to describe the horrors of these two shocks. I have faced a good deal of nature's wildest wrath, the wrath of the ocean and storm and tempest, and in both I have seen the hand of God in death – and other visitations, but these were indeed 'the terrors of the Lord'. Several houses at Bankipore were cracked by the earthquake, the Magistrate's Kutchery being one amongst them, and in the city, the opium godown shared the same fate as well as the great gateway built by Maharajah Metre Jeyt Sing, while many of the pucka native dwellings have bodily fallen. At Dinapore the former Brigade Major's house was split and also some houses between Patna and Diggah.

Eighteen shocks were counted by some, but they appeared continuous. The last one was at 08:00. Almost all the inhabitants left their houses during the continuance of the shocks and remained out the whole night.

(The India Gazette, Calcutta, Monday, 9 Sept. 1833, III, 869, reprinted from Bengal Hurkaru, XII(60), Sat., 7 Sept. 1833)

Patna, 27 Aug. 1833 **VIII**

Last night at about 23:00 we had a most severe shock of an earthquake the like of which I have not witnessed or heard of; it came on at four different times, and the shock was so very great that the whole of Patna appeared as if floating and a great number of houses fell, and various sorts of injury sustained. Rajah Khan Behadoor's Stable fell by which seven of his horses died.

The outer wall of Captain Elliot's house was also levelled with the ground. Mr E. D'Costa's house also cracked at several places and a few of his wall shades fell to the ground. Many of the gentries suffered considerable injury to their property. The alarm was so great that the inhabitants left their house and stood out in the compound with their family the best part of the night. The shock was most dreadful and alarming, we expected every moment to be our last.

(The Bengal Hurkaru and Chronicle, New Series XII, 57, New Series, 4 Sept. 1833, Calcutta)

Purneah, 27 Aug. (now Purnea) **IX**

This place I am sorry to say has been visited by several of the severest shocks of earthquake within living memory of the oldest inhabitant. The following is as correct account of it as I was able to preserve:

1st	shock at 17:30, 26 Aug. 1833, rather slight	
2nd	23:00	severe
3rd	23:18	most violent
4th	23:28	slight
5th	23:32	slight
6th	23:46	slight
7th	01:00	27 Aug. 1833 slight
8th	03:25	slight
9th	05:52	slight
10th	08:00	rather severe

So great was the undulation that birds of every description were driven from their nests, men were scarce able to keep their feet, and the cattle running about wild with fright. During this severe shock, several old buildings in the town tottered to pieces, and part of one of the stations actually partially sank. A heavy cornice of a newly erected wall in a gentleman's bungalow came bodily down and literally smashed a table and some chairs to pieces: every building suffered more or less. A recently vacated upper-roomed house had not an arch left; large masses of bricks had fallen out; the roof in many places slipped and the beams and burgahs separated by an inch or more; the outhouses in this compound became a heap of ruin.

I am led to infer from the stoppage of a clock and other testimony that the undulation came from southward and traversed east. During the 3rd and severe shock a heavy rain fell to the south accompanied by much wind. I have no time to particularize further. You will be glad to hear that no lives were lost, at least, I have heard of none, and I trust I shall not.

(The India Gazette, Calcutta, Fri., 6 Sept. 1833, III, 867, reprinted from the Bengal Hurkaru and Chronicle XII(58), New Series, Thu., 5 Sept. 1833)

Purneah, 27 Aug. 1833 **VII**

The earthquake seems to have been felt there as elsewhere on the night of the 26th: no less than 14 or 15 shocks were experienced – two of them which took place between 23:00 and 24:00 were very severe, and appear to have done a good deal of injury to several houses of the station.

(Reprinted in Bengal Hurkaru and Chronicle, XII, 59 New Series, Mon., 6 Sept. 1833, from John Bull)

Purneah, 11 Oct. 1833 (aftershock)

The 4th Oct. shock at this place though not severe was sufficiently so to be duly appreciated. Upon the testimony of a gentleman whose premises lay not 5 miles of the Nepal boundary, and who was at the time shooting on his grounds, I learn that immediately anterior to the shock, three distinct reports similar to the discharge of heavy artillery were distinctly heard followed by a slight and jerking vibration, which instantly assumed an extraordinary undulation, corresponding with the rise and fall of a heavy swell at sea... in the villages of Furkeah and Shanore... Yours obediently, A reader.

(Bengal Hurkaru, and Chronicle, Sat., 16 Oct. XII(102).)

Rotas hills, 28 Aug. 1833 **IV**

At 23:10 on 26th instant, just about falling asleep, felt my bed shaking and the roof the bungalow creaking; an earthquake says I, and got out of bed immediately, and entirely out of the house? Not a soul near but a chokedar who seemed just to have awoke. I asked him if he felt the earthquake shake, he said he thought the house shook, but it was owing to wind, of which there was only a light air from the NW – a pretty bright moon; this shock lasted not more than a minute I believe; went to bed again, and lay watching, when a second rocking came on, and at 23:28 it came on again, sure enough much more severe and of much longer duration – I really think of not less than 2 or 3 min. I lay quiet some seconds to be certain it was not the effect of fancy, but it became too palpable; the roof of the house was creaking, and the lamp swinging 2.5–3 in. each way.

(Bengal Hurkaru and Chronicle, XII(59), New Series, Mon., 6 Sept. 1833)

Rungpore, 27 Aug. 1833 **V**

We had last night three earthquakes. The first a little after sunset, very short. The second at half past eleven, very strong and it lasted about thirty seconds or more. The third was still more severe and of forty seconds duration. Unlike those in July they began gently and went on fearfully increasing to near the end.

(The India Gazette, Tue., 3 Sept. III, 864)

Tirhoot (Muzaffarpur region), 5 Sept. 1833 IV (?X)

Then comes the 26th – the awful earthquake of which you no doubt ere this had better accounts than I can pretend to give; however, with your permission I will state how I felt myself. At 6:30 there was a slight shock; again at a quarter past eleven I was aroused from my slumbers by a violent shaking of the bed under me, and immediately conjectured what was going on, and made a precipitate retreat to the *maidan* fully expecting the house would be down before I was out of danger. This shock passed over in a short time, I should say it lasted a minute, and I again turned in, and was just on the eve of falling asleep, when came another edition far more severe than the preceding, which again sent me flying or rather staggering, for I certainly found it difficult to retain my gravity. To give you some idea of its tremendous force, I will merely mention the circumstances of my reservoir which was full, having had the water thrown out to the depth of two feet and a half North and South, by the vibration. The damage done to the Pucka buildings and bungalows in the district is considerable, but no doubt still more so at Patna and such like large cities, where the houses are built of frail materials from economy, and shew being the chief object without regard to stability. We have repeated shocks (slight ones) every day since; a very perceptible one yesterday at 3 P.M. and what the end of it all may be a subject of speculation. A gentleman on the border of the Nepaul Terrai writes, that he expects on getting up some of these mornings to see a splendid volcano burning on the top of the mountains. What an addition this would be to their already majestic appearance!

(The India Gazette, Calcutta, 1833, Wed., 18 Sept.1833, III, 877 reprinted from the Bengal Hurkaru)

Tirhoot (Muzaffarpur region) ?IX

The earthquake was very grand here, and equally so all along the Terai, doing great damage of course. Accounts from Nepaul speak of it as awfully sublime at Khatmandoo, the earth rocking like a raft on a rough sea: houses, temples, walls, all tumbled about and many lives were lost. The poor people were driven out for safety into the fields, and the shocks continued at long intervals on the 27th, 28th and 29th.

(The India Gazette, Calcutta, 26 Sept. 1833, III, 884 reprinted from Mofussal Ukhbar 14 Sept.)

Prinsep, H. (ed.) *J. Asiatic Soc. of Bengal*, 2, Miscellaneous, IX, 438–439, August 1833

Note: Text assembled by the editor (H. Prinsep) from newspaper reports and A.C. (= Dr. Archibald Campbell, Assistant Surgeon to the British Legation to Kathmandu). The times are given for the second shock, not the main shock, and were used by Mallett 1852, however, Mallett was unaware of the locations of the Rothas Hills (S. of Patna), Bankura (N. of Calcutta) and Mallai. Prinsep cites Mullye as Mallai. Campbell indicates the Kathmandu time of the second shock as 22:45 which is significantly earlier than times listed from other locations. On page 564 of J. Asiatic Soc. the editor revises the Kathmandu time difference here entered as 12 min to 51 min to yield a Calcutta time of 11:36.

Earthquake of 26 Aug. IX

The daily papers have published notices of this phenomenon as observed at a great many places in the interior of India, with more or less detail, from which the following general facts may be gathered.

The direction was from NE to SW: there were three principal shocks; the first one at about 18:30, the second one at 23:30 and the third one at 23:55 (Calcutta time). In the places where it was most felt, slight and continued vibrations seem to have been experienced for the whole day following. As the time of the second vibration was accurately noted in Calcutta by the stopping of an astronomical clock, we may assume that it was the best point of comparison with the times noted at other distant points. A few of them may be classified as follows:

	Observed h:m	Diff. Long. m	Cal. time h:m	
Katmandu, Nipal, second shock	10:45	+12	10:57	Very severe, loud noise
Rungpur, second shock	11:20	–2	11:18	Many houses injured, very severe, loud noise
Monghyr, second shock	11:27	+7	11:34	Walls cracked, noise heard
Arrah, second shock	11:15	+14	11:29	Walls injured
Under Rotas Hills, second shock	11:10	+20	11:30	
Gorackpur, second shock	11:20	+19	11:39	Walls cracked, etc.
Allahabad (vague) second shock	11:00	+28	11:28?	Hollow sound from river
Bankura, second shock	11:30	+4	11:34	None such since 1814
Calcutta, second shock			11:34:48	No injury done

At Monghyr, Rungpur, Muzaffarpur, Mallai and other places within the direct line of influence, many houses were destroyed or injured, and the alarm was great. At Katmandu, the following extract of a letter from Dr A Campbell, dated the 28th instant will show that the consequences were more serious, and judging by the course of the phenomenon we may reasonably fear some dreadful catastrophe towards Lassa on the north of the great Himalayan range.

'On the evening of the 26th, at about 6 O'clock, the valley and the neighbouring hills were visited by a severe shock of an earthquake: it lasted about 40 s, and during its continuance, there was a distinct audible noise as of an ordnance passing rapidly over a drawbridge. It seemed to come from the east, and I felt that it was travelling with the speed of lightning towards the west, and just under my feet: the houses shook most violently, and trees, shrubs and the smallest plants were set in motion, not shaking but waving to and fro from their very roots. No damage was done to life or property. At 22:45 we had a similar shock in brevity and duration, and at 23:00 a most tremendous one. It commenced gradually, and increased until the houses, trees and everything on the face of the ground seemed shaken from their foundations. The earth heaved most fearfully, and when the shock was at its worst we heard the clashing of falling tiles and bricks in every direction; and to add to the impressiveness of the scene, a general shout rose from the people in all directions. The murmur of human prayers was carried audibly from the city to our grounds (a mile), and nothing could be more imposing and vast than the scene. In a dead calm the noise of a hundred cannon burst forth: full-grown trees bended in all directions, and houses reeled about

like drunken men. In our grounds no lives were lost, but in Katmandu 19 persons were buried under the ruins of their own houses, and in the towns of Bhatgaon and Patan, many more. The great shock continued for nearly a minute, and during the following hour there were six distinct and strong shocks, the ground in the intervals between scarcely, if at all, steady; and from this time till yesterday morning there were upwards of 20 distinct and sharp shocks. The loss of property has been very great, 125 houses fell in Katmandu during the night of the 26th, and nearly as many more were levelled with the ground. Up to this time, in consequence of the torrents of rain that came down, finishing the work of destruction commenced by the earthquakes, the city and town have been evacuated; men, children, and women of the *purdah*, rich and poor have been and still are on the plains about the towns. Innumerable temples were destroyed, and the very gods of them were crushed to atoms. A fine and large brick temple (100 ft high), built in imitation of the great one at Jagarnath, came down by the run early yesterday morning, and two fine pillars by Bhim Sen were demolished by the shock. All yesterday and last night we had occasional small shakes, but none equal to the great one we had on the 26th.'

A subsequenct note from the same gentleman, dated the 30th instant, gives further particulars of this disastrous event:
'We still continue to be visited by occasional shocks of earthquake, all less violent than the great one on the 26th, but sufficiently alarming. This morning when at breakfast, we had a rather sharp one: they all seem to come from the same direction; that is from the east and north-east. The places east of Katmandu have suffered most: Bhatgaon, a large town, has been almost entirely destroyed; upwards of 1000 houses have been levelled with the ground, and few have escaped serious injury. 300 souls have perished in this town (Bhatgaon) alone, and the total number of lives lost throughout the valley, as yet ascertained, is estimated at 500. The unfortunate people in many instances are in sore distress; their stores of grain being buried beneath the ruins of their late dwellings, and without money to purchase other food. The grain shops as well as all others are shut, and the people dare not return to their houses but remain without sleep or shelter in the open air, under torrents of rain. The house of Matabar Sing (a goodly modern mansion) is quite destroyed, and the large garden houses of Bhim Sen and his brother Rau Bir are rendered, for the present, untenable. Scarce a large house in Kathmandu has escaped injury. The fort at Chisopani, on the road to this from the plains, is much injured, and almost all the Government buildings have sustained great injury.' – A. C.

Campbell, A., *J. Asiatic Soc. Bengal*, 2, 564–565, November 1833

II. Account of the earthquake at Kathmandu. By A. Campbell, Esq. Assistant Surgeon, attached to the Residency.

On 26 Aug. last, at about 18:00, a smart shock of an earthquake was experienced throughout the valley and the neighbouring hills, westward in the valley of Nayakot and Duny Byas, eastward at Panouti, Baneppa, Dulkele and Pholam Chok, and southward at Chitlong, Chisagarhy, Etounda and Bissoulea. The shock was preceded by a rumbling sound to the eastward. The motion was undulatory, as of a large raft floating on the ocean, and the direction of the swell was from NE towards the SW. The shock lasted about 1 min. At 22:45 (Footnote: Not by chronometer, but by a good-doing clock which stopped during the great shock. Its pendulum vibrated north and south. [If the clock was set by the sun, the shock must have been 51 min earlier than Calcutta. – Ed.]) of the same day another shock of equal duration and of the same character occurred, and at 22:58, a third and most violent one commenced: at first it was gentle rocking motion of the earth, accompanied by a slight rumbling noise; soon, however, it increased to a fearful degree, the earth behaved as a ship at sea, the trees waved from their roots, and houses moved to and fro far from the perpendicular. Horses and other cattle, terrified, broke from their stalls, and it was difficult to walk without staggering as a landsman does on ship board. This shock lasted about 3 min in its fullest force. And the following is as correct an estimate as can be ascertained (without official documents) of the damage done by it to life and property throughout the great valley and neighbouring districts of Nipal. It is believed that the first two shocks were harmless.'

[Dr. Campbell's subsequent letters inform us that there have been frequent shocks of less violence since the above, many of which (on the 4 and 18 Oct. particularly) were felt at Calcutta, Monghyr, Chittagong, Allahabad and Jabalpur nearly simultaneously. On the 26th (Sept.), he writes, 'At 10:45 a sharp shock of the dangerous or undulating kind occurred. The embassy has returned from China, and I am informed that the great shock was not felt in Lassa, so that it would appear to have been confined to India within the Himalaya.' – Ed.]

Number of lives lost and buildings destroyed

Named location	Inferred location		Killed	Wounded	Houses
British Residency grounds			0	0	1
Kathmandu			60	38	400
Two pillars built by the minister, each upwards of 100 ft high, the large temple of Jagarnath, built by Ran Bahadur, after seven years of labour, and about a dozen temples were destroyed. The modern built garden houses of several members of the minister's family have been rendered untennantable, one of them, a handsome and ornamental edifice, came to the ground.

Baghmati	Bungamati	27°37′, 85°18′	0	0	80

contd...

A crack in the ground of 20 ft in length was observed at this village on the morning of the 27th; the entire number of houses in it was 206, more than a third of the whole were destroyed, and about 100 men [*more?*] were much damaged. The injury sustained here is probably greater than in any other part not to the east of Kathmandu.

Listi gaon	Listikot	85.954°, 27.89′	0	0	0

Mundun Pahar, Kassa (Darm = Khasa, 85.95°27.00′), Kuti. In this direction the earthquake was much more severely felt. Kuti, a town on the Bhote frontier on the road to Lassa, is said to have been nearly destroyed, it contained 600 houses, only 50 of which remain. At Listi gaon (?Listikot), also on the Bhote frontier, a large portion of hill came down, and an iron bridge was destroyed. At Kan Sing Choke (?Choksum 86.00°28.07′), in the same direction, vulgar report says, that for 5 days before the earthquake took place, noises similar to the firing of cannons were heard as if underground: and in this neighbourhood the high road to Lhasa is said in many places to be blocked up by the fallen earth from the mountains. Shipa – the country residence of Colonel Runbir Sinh, 20 miles from Kathmandu on the Lhasa road, by the Kuti Pass, was seriously injured. Many small houses attached were destroyed and several lives lost.

West of Kathmandu

Swambunath	Swayanbhunath	27°42.3′, 85°17′	0	0	3

One small temple was destroyed, and the large one a little injured. The form of the large one must have preserved it. It is the chief buddhist temple in the valley, built in the fashion of that religion – an immense circular mound of brick work, surmounted by a four-sided spire or jweet.

The fort here was much injured: a large portion of breastwork facing the south had fallen, and the wall in many other places, although not fallen, was seriously injured.					
Mukwanpur	Mukwanpur	27°25′, 85°09′	0	0	0
The fort here has also suffered, but in much less degree than the fort at Chisapani.					
Total			414	172	4040

The above shows that the earthquake was much more severe to the north and east of the valley than here; and that even within the valley it was much more violent to the east of Kathmandu than at the capital itself, or other places to the west of it. The town of Bhat gaon is not more than 8 miles in a straight line from Kathmandu, and even there its violence must have greatly exceeded what it was at the latter place. To account for the immense disproportion in the loss of life and property at both the places, something may be allowed for the more frail state of the buildings at Bhat gaon; but this is not sufficient, and this circumstance must be considered as inexplicable as most others attending this fearful phenomenon. The brahmans of Nipal say (and it is believed with truth) that the occurrence of a more violent earthquake than this is recorded in their histories. It was about 600 years ago, and then the cities of Mangah, Patan and immumerable other towns were utterly destroyed and thousands of their inhabitants killed: the modern capital Kathmandu did not then exist.

Campbell, A., Further particulars of the earthquake in Nepal. *J. Asiatic Soc. Bengal*, VI, 636–639, December 1833

In pursuance of the attempt made before to note the destructive effects of the earthquake of 26 Aug. last throughout the valley of Nepal and its immediate neighbourhood, and with the hope of showing as correctly as my information will permit the probable seat or centre of this commotion, I beg to offer the following memoranda of other places at which the shock was experienced, as well as its comparative degree of intensity at each.

The means of estimating the violence of this phenomenon are, of course, most defective, if not wholly inadequate to the purpose: but in the absence of better data, the ascertained amount of damage done to the frail and perishable works of man may be received as an index of its intensity at one place, compared with that of another, and in conformity to this mode it would appear that the most extreme violence of the shock, as far its occurrence is yet known, was expended in the tract of country extending from this side of the great Himalaya range on the north to the course of the Ganges on the south, and from the Arun river (in the Nepal hills) on the east to the eastern branches of the Trisul Ganga on the west, comprising a space of about 200 miles from north to south and 150 miles from east to west. In this space, the valley of Nepal, though not geographically the centre point, is most assuredly the portion that has suffered the greatest violence of the calamity; and unless the inexplicable producing causes have been expended in the frequent and severe shocks that have to this day continued to recur, we may from our experience of the progress of the earthquake in other parts of the world, with reason, as we ought with resignation, look forward to further and more violent exhibitions of the same terrible nature.

In the notice of the earthquake by the secretary of the Asiatic Society, in his journal for August, he expressed a belief that the greatest intensity of the shock would be found to have occurred beyond the Himalaya, in the direction of Lassa; and judging from the direction from which the shock would be found to have proceeded and its intensity in the valley of Nepal, such was the probability, though other has turned out to be fact, and that upon good authority.

The recent return of an embassy from Nepal to the court of the celestial emperor has furnished authentic information on this subject, which otherwise might have been long wanting; and the hole tenor of it shows that the great Himalayan range itself and the country on *this*

side of it alone was the theatre of the earthquake's presence, and that it was not even in the slightest degree felt beyond a very short distance on the Tibetan side of those huge mountains.

The embassy was at Lassa on 26 Aug., when and where the shock was not experienced. At Digarchi, in the following month, it first received accounts of its occurrence from Nepal; to the inhabitants of that place the circumstance was known only from reports brought from this side of the mountains; along the road from Digarchi, the answer to all inquiries was the same. 'No earthquake on 26 Aug.', and not until its arrival at Tingri was it found that the shock had been felt. Tingri is a small Chinese post, immediately beyond the great Himalaya, and the first stage on the tableland (as it is called) of Tibet, going from hence to Lassa (by the Kuti or eastern pass from the Valley of Nepal). From Tingri to Kirung, a distance of 8 or 10 marches, the route is nearly due west, running along; and through the northern side of the Himalaya, and throughout this tract, though but thinly inhabited, authentic reports of the occurrence of the shock were received. By Kirung (the eastern pass from the valley into Bhote), the mission penetrated the great range, and at each stage (four in number through the pass) intelligence of the occurrence was communicated by the few individuals who inhabit that wild and sterile region. But such information was not required, as its effects were sufficiently manifest: in the village of Kirung itself, supposed to contain 400 houses, 60 were fairly demolished and many more seriously injured: two men had been killed under the ruins of their houses, and about a dozen injured.

From the exit of the pass to Kathmandu there are no towns along the route, and scarcely any villages; but at many places, insulated (?isolated) houses of the mountaineers had been thrown down, and the precipitous banks of hills and mountains had been hurled into the subjacent valleys.

This shows the extent of damage done towards the north, and enables us to fix the line of Tingri (Lat. 28°) as the northern limit of the earthquakes presence, and reports would show that of Jabalpur and Calcutta to have been the southern one. Rangpur defines the east (footnote from editor – Mr Walters informs me that it was also felt at Chittagong), and Delhi the west.

Northeast from Kathmandu as far as Dulka and Kuti, the violence would seem to have been greater than in the valley. West from Kathmandu it diminished at every step. At Gorkha, only two houses were destroyed; at Palpa, none; and at Doti, on the borders of Kumaon, the shock was felt, but by no means severely. It will strike everyone as remarkable that, while here the shock was more violent than elsewhere, its effects should not have been felt equally at as great a distance from hence to the north as to the south.

I subjoin an accurate register of the shocks which have occurred up to this date, given to me by Captain Robinson. Many of them have been severe, and throughout the whole course of these visitations, there have been two distinct varieties observed in the characters of the shocks, all those at the commencement were undulatory or swinging kind; the others wanted this swell, and were a violent up and down shaking with little vertical motion. The first may be called horizontal, the latter the vertical, variety. The former alone have been destructive to property, while the latter, from the greater noise by which they are accompanied, and the more rapid oscillations of the ground, are perhaps more terrifying.

Register of earthquakes at Kathmandu, from 26 Aug. to 26 Nov. 1833 inclusive

Aug. 26	17:55, 22:50, 22:58, duration 3 min, nine others, all horizontal
Aug. 27	04:53, 05:20, 05:26, horizontal
Aug. 28	07:25, 16:55, horizontal
Aug. 30	09:00 and 3 other shocks
Aug. 31	2 slight during the night
Sept. 1–11	10 slight shocks
Oct. 4	07:30, Smart vertical shock, 1 min duration, felt at Gorackpur and Allahabad
Oct. 18	13:15, severe, vertical, duration 1 min, felt slightly at Allahabad
Oct. 26	10:37, slight
Nov. 8	01:35, slight
Nov. 16	24:00, slight
Nov. 26	23:45, severe, vertical 1 min duration (occurring at the full moon)

How fast is ultrafast chemistry?

Biman Bagchi

Solid State and Structural Chemistry Unit, Indian Institute of Science, Bangalore 560 012, India

The field of ultrafast chemistry has seen a string of remarkable discoveries in the recent years. In this article we briefly discuss some of the problems solved recently. The understanding that has emerged from these studies has important consequences not only in chemistry but also in diverse biological processes.

HOW fast is the response of a liquid to a given perturbation? The answer, of course, depends not only on the nature of the liquid but also on the nature of the perturbation itself. If the perturbation is slow, such as the shearing force on a liquid, then the response, the flow of the liquid, is also slow. And, if the perturbation is fast then the response is also fast. The question that a chemist has always asked is: How fast can this response be? What determines the limit? To a chemist, this question is not an idle one, but is profoundly related to the understanding of the effects of the solvent on the various chemical reactions[1–12] – we shall give examples later. And as the way we understand things now, the answer is also important to many biological reactions. Thus, we can formulate the question more precisely now: How fast is the response of chemically (and biologically) important solvents to various elementary chemical events that lead to much of the natural change around us?

The quest for the answer to the above question has occupied generations of chemists and finally the answer is beginning to take shape, thanks to some remarkable developments in this area in the last 3–5 years. For example, it was only very recently that the solvation dynamics of an ion in liquid water could be measured for the first time[11] – the dominant time constant is only about 50 fs (1 fs = 10^{-15} s)! No one had imagined that dynamics in water could be so fast. The importance of this particular experiment is that the dynamics was measured directly in the time domain. In fact, several such remarkable results have been obtained in the recent years. In the process many old ideas and notions have been found to be inadequate while new ones are still being tested. The objective of this article is to convey to the reader at least a part of the excitement of the field of ultrafast chemical dynamics.

There are many chemical reactions that occur at a great rate. It is only after the availability of ultrashort laser pulses and after the perfection of the associated detection techniques that study of these processes became possible. Figure 1 shows the evolution of time scales in the order they became available and a few examples of the dynamical processes which could be studied with the available time scales. It is important to realize that the underlying physical and chemical phenomena in different time scales are often profoundly different. In many cases the availability of shorter time scales meant more accurate measurement than was hitherto possible, often leading to new understanding. In some other cases completely new phenomena could be studied.

A key question in discussions on ultrafast processes is the limitation of the time scales posed by the Heisenberg uncertainty principle. When the time scales touch the femtosecond domain (the right bottom corner of Figure 1), then this certainly becomes a valid question. If we consider a relaxation that occurs with a time constant of 10 fs, then a quick calculation shows that the uncertainty principle imposes the limit that the minimum uncertainty in the frequency is 5×10^{13} Hz or, equivalently, 125 cm^{-1}. Thus, the uncertainty principle may make studies of vibrational relaxation irrelevant in some cases. However, the chemical processes that involve electronic relaxation will not be affected. There are,

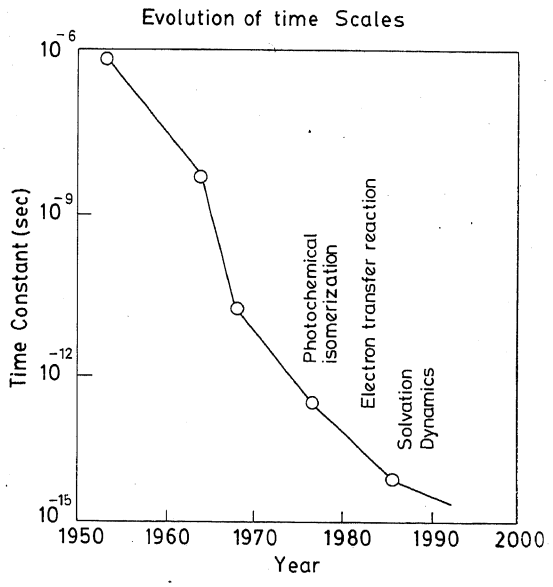

Figure 1. A schematic illustration of the evolution of time scales, where the experimentally accessible time constants of chemical processes are plotted against the years they became available. The three chemical relaxations discussed here, namely, isomerization dynamics, electron transfer reactions and solvation dynamics, are also shown in the same figure, approximately indicating the time when their modern studies became possible.

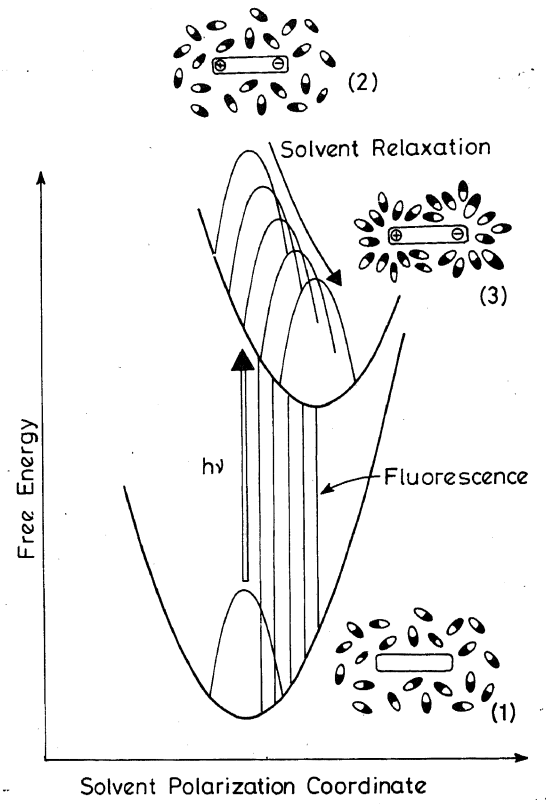

Figure 2. A schematic illustration of physical processes that accompany solvation dynamics and give rise to the time-dependent fluorescence Stokes shift (TDFSS). The state marked (1) is the unchanged, nonpolar state in equilibrium with the solvent. Optical excitation drives the system to the nonequilibrium state (2), where the solvent is still in the Franck–Condon state of the ground nonpolar molecule. Subsequent solvent reorganization leads to the stabilization (that is, solvation) of the polar molecule. As the system relaxes, the fluorescence from the solute shifts to the longer wavelength (that is, the spectrum gets red-shifted). The time dependence of this Stokes shift can be measured in experiments.

however, several other practical difficulties which make reliable study in the time scales below 20 fs difficult, at least at present. However, there may be interesting chemistry even in such short time scales. For example, the initial part of electron solvation dynamics after two-photon ionization of water molecules in liquid water occurs in times less than even 10 fs. During this time, the important process of the dephasing of the electronic wave function is virtually complete. It is not yet clear as to how to measure such processes.

In this review, we shall briefly touch upon a few of the chemical processes which have been studied intensely in the last few years. The examples are chosen from the author's own experience in the field, so they are not exhaustive. Also, the emphasis is entirely on the phenomena and their understanding – technical details (both experimental and theoretical) will be omitted. The list of references is not exhaustive. There are several reviews[1–8] and books[9, 10, 12] that have appeared in the last 5–6 years which contain the details and, in addition, provide useful starting point for the nonexpert. Boxes highlight the material expanding points briefly considered in the main text.

Solvation dynamics in dipolar liquids

The study of solvation of chemical and biological molecules is as old as chemistry and biology. Very few people, therefore, expected solvation dynamics to occupy the centre stage in ultrafast chemical dynamics. However, things turned out differently for various reasons. First, polar dye molecules serve as excellent probes in the study of solvation dynamics as these molecules have large polar stabilization energy in the excited state. This is because these dye molecules, upon excitation, often undergo a large increase in the dipole moment, or sometimes may even photoionize. Therefore, optical excitation prepares the molecule in the Frank–Condon state, which is of much higher energy than the minimum of the potential energy in the excited-state surface. This situation is shown in Figure 2. Subsequent to excitation, the solvent molecules rearrange and reorient to stabilize the new charge distribution in the excited state. The resultant change in energy is the solvation energy, which, as already mentioned, may be several electron volts. The second reason for the choice of dye molecules as suitable probes is that they often have easily detectable fluorescence with long life times, so one can easily study the time dependence of the Stokes shift of this fluorescence as the solvation energy of the dye molecules evolves. This time dependence is described by the solvation time correlation function, which is defined as[13]

$$S(t) = \frac{E_{\text{solv}}(t) - E_{\text{solv}}(\infty)}{E_{\text{solv}}(0) - E_{\text{solv}}(\infty)}, \qquad (1)$$

where $E_{\text{solv}}(t)$ is the solvation energy of the newly created ion at time t. This function is defined such that it

Box 1.

In the experiment done by Jimnez *et al.*[11] a Coumarin 343 dye (sodium salt, 10^{-4} M), in water, is excited with an ultrashort optical pulse. The evolution of the fluorescence spectrum of the Coumarin 343 anion (Figure B1.1 *a*) has been studied to follow the solvation dynamics of the anion. The atom-centred charges in the ground state and in the excited state, after excitation by optical pulse, are shown below in Figures B1.1 *b* and *c*, respectively.

$C343^-$

(*a*)

(*b*) (*c*)

The volume of each sphere is proportional to the charge on that atom and black denotes the negative charge. After excitation, the resultant fluorescence is resolved by a time-variable gate based on frequency-summing the fluorescence with a second ultrashort laser pulse (details given in the experimental section). As the solvent relaxation proceeds, there is a continuous shift of the emission spectrum towards the red end. The change in the peak frequency with time can be determined from these data. Thus, by observing the peak of the fluorescence spectrum at times t, zero and infinity, one can monitor the solvation dynamics of the anion and construct the solvation time correlation function $S(t)$ [vide equation (1)]. In the experiment a coherent Mira mode-locked Ti:sapphire laser has been used. The laser was operating at 850 nm. The second harmonic (425 nm), generated in a beta barium borate crystal, was used to excite Coumarin 343 (flowing in a quartz cell). The 850 nm light has been used to gate the fluorescence by mixing the fluorescence emission in another beta barium borate crystal. The cross-correlation of the two pulses (425 nm and 850 nm) was measured to be 100–110 fs (full width at half maximum). The intensity of the sum frequency has been measured as a function of the time delay between the two pulses. By angle-tuning the mixing crystal, emission decays were collected at certain intervals. The femtosecond fluorescence upconversion data obtained at a range of wavelenghts as a function of delay time has been plotted. These data can be used to construct a set of time-resolved emission spectra. The $S(t)$ can then be calculated from the set of spectra as discussed above.

decays from unity to zero as the solvation proceeds from $t = 0$ to $t = \infty$. The solvation dynamics is reflected in the red shift of the fluorescence spectrum and this experimental procedure is known as time-dependent fluorescence Stokes shift (TDFSS). One may expect that TDFSS will strongly depend on the nature of the solute probe, which can complicate the study of solvation dynamics. Fortunately, one finds that $S(t)$ is largely probe-independent, for reasons which are only partly understood, to be discussed later. The second reason for the great interest in solvation dynamics was the realization that it can significantly influence many chemical reactions, especially electron and proton transfers in polar liquids. Yet another reason is that the standard continuum model theories predicted that $S(t)$ would decay at a rate much faster than the rotational (and, of course, translational) relaxation. Thus, for water it predicted that the decay time would be about 250 fs (refs. 3, 13), which was startling even in the late eighties.

Over the last decade, $S(t)$ has been measured for a large number of polar molecules in different solvents. In the first phase (1986–1990), the experiments were done with time resolution only in the picosecond range. The solvation time correlation function was found to be non-exponential and differed from the predictions of the continuum models. During this period, an old comment of Onsager[14] became the topic of much discussion and we briefly discuss it here as it gave rise to interesting physics. In the Banff Conference on the 'Solvated Electron' in 1976, Onsager made the interesting comment that the polarization structure of an electron should form from outside in. That is, the molecules far from the electron should rearrange first, while the nearest-neighbour molecules relax the last. This suggestion came to be known as Onsager's 'inverse-snowball

Box 2.

The theory of solvation dynamics has undergone rapid development in the last few years to keep pace with the experiments. The most successful of the theories assume a linear response of the dipolar liquid. Under this assumption, the non-equilibrium response function $S(t)$ (defined by equation (1) of the text) is equal to the equilibrium solvation-energy–energy time correlation function, $C_{EE}(t)$, defined by

$$C_{EE}(t) = \frac{\langle E_{solv}(0)\, E_{solv}(t)\rangle}{\langle E_{solv}(0)\, E_{solv}(0)\rangle}. \qquad \text{(B2.1)}$$

This assumption leads to the simplification that one needs to consider only an equilibrium time correlation function, which is simpler to deal with. The microscopic calculation of $C_{EE}(t)$ is somewhat involved and the details are beyond the scope of this review. However, if one assumes that the main component of the solvation energy of an ion is the interaction between the bare electric field of the ion and the dipolar molecules of the liquid, then the final expression is simple and is given by[22-25]

$$C_{EE}(t) = \frac{\int_0^\infty dk \left(\frac{\sin kr_c}{kr_c}\right)^2 \mathcal{L}^{-1}\left[1 - \frac{1}{\varepsilon(k, z)}\right]}{\int_0^\infty dk \left(\frac{\sin kr_c}{kr_c}\right)^2 \left[1 - \frac{1}{\varepsilon(k)}\right]}, \qquad \text{(B2.2)}$$

where $\varepsilon(k, z)$ is the wavevector (k) and frequency (z) dependent dielectric function and $\varepsilon(k) = \varepsilon(k, z = 0)$ is the static dielectric function. r_c is a cut-off distance due to the short-range nature of the repulsive interactions, z is the (Laplace) frequency and $\mathcal{L}^{-1}$ denotes the Laplace inversion with respect to the frequency z. The standard dielectric constant is $\varepsilon_0 = \varepsilon(k = 0, z = 0)$. The above elegant expression has many satisfying features, one of them is that one recovers the well-known continuum model result simply by replacing $\varepsilon(k, z)$ by $\varepsilon(k = 0, z)$; the latter is the frequency-dependent dielectric function (z) measured in macroscopic experiments. The calculation of the wavevector- and frequency-dependent dielectric function forms the crux of the problem. This dielectric function $\varepsilon(k, z)$ can be shown to be given by the following expression[22]:

$$1 - \frac{1}{\varepsilon(k, z)} = \left(1 - \frac{1}{\varepsilon(k)}\right) \frac{1}{z + \Sigma(k, z)}, \qquad \text{(B2.3)}$$

where $\Sigma(k, z)$ is a generalized rate. This generalized rate derives contribution both from the rotational and the translational motions of the solvent molecules and also depends on the orientational pair correlation functions of the dipolar liquid. An important aspect of this rate is that in the absence of the translational contribution, it gives a smaller rate at intermediate wavevectors than at small values of k. This seems to agree with Onsager's 'inverse-snowball model' discussed in the text. However, when the translational component is efficient, then the complete reverse occurs, leading to the breakdown of the 'inverse-snowball model'. This theory has been applied to study solvation in many dipolar liquids. In Figure 3 the prediction of this theory has been compared with the experiments of Jimnez *et al.*[11] Note that the agreement is nearly perfect.

picture'. This also suggests that the solvation energy relaxation would be intrinsically nonexponential, as many, length-dependent, time scales are involved. Initial theoretical studies[15] supported this picture. However, it was argued later that the contribution of solvent translational modes may lead to the breakdown of the inverse-snowball picture[16]. More recently, it has been argued again that the Onsager picture may after all be correct for electron, but not for ions[17, 18]. The latest suggestion is that the electron being a very light particle will travel a long distance before it settles down in an existing trap. The dipolar molecules further from the electron can relax but the ones close to it must wait[18].

The most exciting experimental work on solvation dynamics has, however, taken place in the last 3 years only and the results will have far-reaching consequences. We shall refer to this period as the second phase. This started with the work on solvation of a dye, LDS-50, in acetonitrile reported from Fleming's laboratory at the University of Chicago[19]. This landmark experiment showed that solvation dynamics is biphasic with an ultrafast Gaussian component which decays with 80% of the total solvation energy within 200 fs. This is followed by a slow exponential-like decay with time constant of about 1 ps. This result was found to be in agreement with both computer simulation[20, 21] and theoretical[22] studies. However, the most interesting study, reported only last year, again from Fleming's group, is the solvation dynamics in water[11] (Box 1). As mentioned earlier, the results were remarkable. The solvation was found to be again biphasic. The initial Gaussian component decays with a time constant of less than 54 fs while the long time decay component can be described as a biexponential with time constants equal to 126 fs and 880 fs.

Figure 3 shows the solvation time correlation function in water. What is also interesting is the agreement of the long-time components with the earlier experimental results of Barbara and Jarzeba[3], who could not detect the ultrafast component because of limited time resolution. The solvation time correlation in methanol also contains an ultrafast Gaussian component with a time constant of about 70 fs. However, the relative weight of this part is somewhat less (about 30%) although still significant.

What is the origin of such ultrafast solvation in water, acetonitrile and methanol? These three liquids are quite different from each other and it is instructive to compare their dynamical features before we comment on the physical origin. Water, because of its small molecular weight and the extensive hydrogen bond network, has well-defined high-frequency vibrational modes. However, the single-particle orientation of water molecules is rather slow, with a correlation time of about 9 ps, due to the same hydrogen bonding. Acetonitrile, on the other hand, has fewer high-frequency vibrations, but orients very fast, with a correlation time of 0.3 ps. Methanol is again different. Because of chain-like hydrogen bond character, it has certain degree of high-frequency vibration, slow overall rotation but very fast rotation around the C–OH bond, which gives rise to a very fast polar response. All these details seem to be important in solvation dynamics[23].

We now turn to the explanation of the origin of the ultrafast component. Theoretical studies indicate[22–25] that all the natural fast dynamics of the system couple in different ways with the long-wavelength polarization fluctuation to give rise to the ultrafast component. This is because the main contribution to ion solvation energy comes from the long-wavelength part of the polarization, which is created in the liquid by the ion (Box 2). Now, the force constant for the longitudinal polarization fluctuation in a strongly polar dipolar liquid is large. Thus, the driving force to make ion solvation very fast exists in all strongly polar liquids. However, for solvation to be really fast, the liquid itself must be able to respond on the ultrafast time scale. This is where water and acetonitrile (and to smaller extent methanol and perhaps formamide) are exceptional. Water, due to its high-frequency vibrations and intermolecular vibrational modes, and acetonitrile, due to its fast rotational motion, can respond at a very high speed. The explanation given above is borne out by microscopic theory as shown in Figure 2.

Actually, even in these liquids, all is not ultrafast. Just as the rotation of water molecules is rather slow, so also the response to perturbations that vary on molecular length scales. These responses are also probed in many chemical processes, even in water. As discussed above, several rather unconnected (both microscopic and macroscopic) factors combine to give rise to the dominance of the ultrafast component in the solvation dynamics in water and acetonitrile.

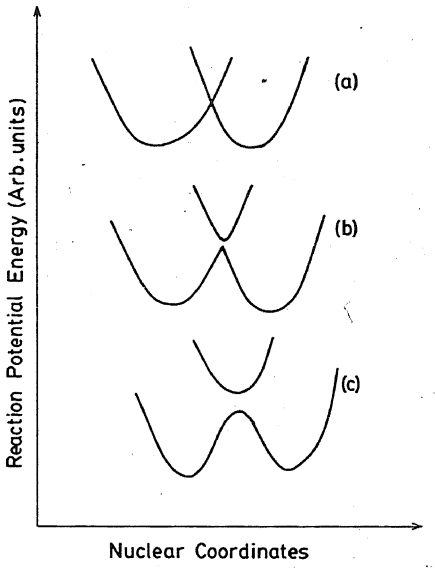

Figure 4. A schematic illustration of the nature of electron transfer reaction, based on the reaction potential energy surfaces. Depending on the strength of interaction between the two participating surfaces (corresponding to reactant and product states), the electron transfer can be classified as nonadiabatic, (case (a)), weakly adiabatic (case (b)) and adiabatic (case (c)).

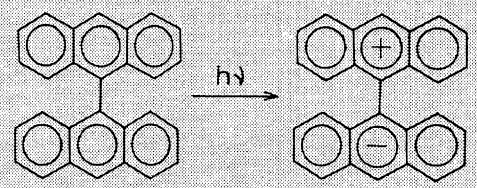
Electron transfer reactions

Electron transfer reactions are ubiquitous in chemistry and biology. The initial studies were motivated by the desire to understand acid–base equilibrium and also many organic reactions involving electron transfer as a key step. With the advent of laser it is now possible to study many kinds of electron transfer reactions, especially those occurring in the excited state, for the first time. The reason is that many of these reactions were found to proceed at exceedingly fast speed, often with time constants in the subpicosecond range. Well-known examples are electron transfer in a photosynthetic reaction centre, fluorescence quenching in excited betaines and ion pair formation in various charge transfer complexes. We address below only the recent advances in understanding solvent effects in ultrafast electron transfer reactions in solution.

The key to the great success of the Marcus theory[26] lies in the choice of the reaction coordinate. The motion of the system on the reaction potential energy surface along this coordinate takes the system from the reactant surface minimum to the product surface minimum. In conventional chemical picture, this coordinate is usually some distance or angle and its nature is clear from the beginning. The situation is different for the electron transfer reaction. In this case, often no chemical bond is broken or formed. The major part of the activation energy comes from the interaction between the reaction system and the dipolar liquid and not from any intra-

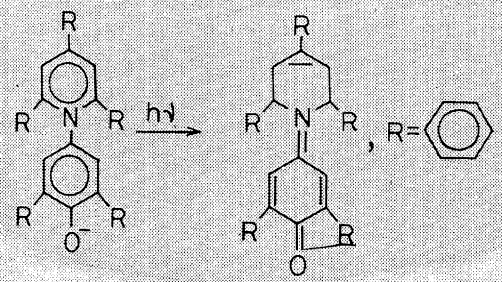
molecular potential. Thus, the reaction coordinate is collective in origin. In the Marcus theory the reaction coordinate is essentially the solvation energy difference between the reactant and the product. However, in order to specify the nature of any electron transfer reaction we must know the nature of interaction between the reactant and the product surfaces. Interestingly, this interaction itself is determined by the nature of the Born–Oppenheimer surfaces as a function of the nuclear coordinates. Thus, in order to understand the electron transfer reaction one must consider the potential energy surface as a function of both the reaction coordinate and the nuclear coordinate. The reaction potential energy surface for several cases is shown in Figure 4. If the reactant and the product surfaces interact very weakly, then the reaction can be considered as a transfer of the electron from the former to the latter at the crossing point and the reaction is termed 'nonadiabatic'. On the other hand, if the two surfaces interact strongly near the crossing, then the electron transfer occurs on one surface (which is given by a combination of the two parent surfaces according to the rules of quantum mechanics) and the reaction is termed 'adiabatic'. The experimental situation often lies between these two broad classifications and is termed loosely as 'weakly adiabatic' or even 'weakly nonadiabatic'. This intermediate situation is shown in Figure 4 *b*.

Recent studies[27–33] have critically examined the dynamic effects of solvent on various electron transfer reactions (Box 3). One is particularly interested to know what effects the newly discovered ultrafast solvation could have on electron transfer reactions. The answer depends on the 'adiabaticity' of the reaction. For nonadiabatic reactions even the ultrafast polar response was found to be not fast enough to affect electron transfer seriously. The situation is rather different for weakly adiabatic electron transfer. Here the first and foremost effect is that the rate of barrier crossing increases by almost an order of magnitude over the old estimates that ignored the ultrafast solvation effects[31–33]. This is true not only for water, but also for the other two ultrafast solvents, acetonitrile and methanol. For acetonitrile some additional interesting features appear. For this solvent the reactive friction (which arises from coupling between the electronic charge and the solvent) becomes so small that the electron transfer is controlled not by the rate of barrier crossing but by the rate of energy diffusion to the barrier from the reactant well. Electron transfers in water and methanol are predicted to be in the normal regime. In fact, it is rather ironic that ultrafast solvation in water implies that this solvent will be able to respond very fast to chemical changes during a reaction which, in turn, will not show any dynamic solvent effects[32, 33].



The Marcus theory predicts a parabolic dependence of reaction rate on the free energy of the electron transfer reaction (Box 4). Although this dependence was predicted in 1956, its verification had to wait till the 1984 landmark experiment of Miller *et al.*[34]. These authors measured the rate of electron transfer across a bridge of organic groups of varying length. Subsequently, several confirmations of the parabolic dependence have been reported[35]. However, there are also several recent studies of ultrafast electron transfer which found interesting breakdown of the Marcus parabolic dependence[36–40], due to various reasons. One such example is shown in Figure 5, where the rate of charge recombination (CR) of newly formed contact ion pair (CIP) is plotted against the free energy of reaction. The rate increases in the normal region with decrease in the free-energy gap. Murata and Tachiya[40] have recently provided an elegant explanation of this non-Marcus energy gap dependence by invoking the interplay between relaxation and electron transfer. A more detailed theoretical work by our group[41, 42] has shown that the above interplay can give rise to highly nonexponential decay of the reactant population.

Box 3.



A very large number of experimental studies has been carried out in the recent years to understand various factors that influence electron transfer reactions. Three extensively studied examples are shown below:

(a) $Mn^{2+} + Mn^{3+} \Leftrightarrows Mn^{3+} + Mn^{2+}$

(b)

(c)

where (a), (b) and (c) correspond to the normal, zero-barrier and the inverted regime of electron transfer, respectively. Many different experimental techniques are being used routinely to study the dynamics of electron transfer. These include the rate of disappearance of fluorescence from the reactant well (due to electron transfer), femtosecond excited-state absorption and also the ground state recovery.

Box 4.

In the Marcus theory, the reaction coordinate (X) is a collective quantity and is defined by the following expression:

$$X = \int d\mathbf{r}\, \Delta \mathbf{D}(\mathbf{r}) \cdot \mathbf{P}(\mathbf{r}), \qquad \text{(B4.1)}$$

where $\Delta \mathbf{D}(\mathbf{r})$ is the change in the displacement vector due to the charge redistribution owing to the electron transfer and $\mathbf{P}(\mathbf{r})$ is the polarization field. Note that here the reaction coordinate itself is an energy. The reaction potential energy has minima corresponding to the reactant and the product states. In the Marcus theory, electron transfer is considered to be mediated by solvent polarization fluctuations and distinction is made between the nonadiabatic and adiabatic electron transfers. For the former case, the rate is given by the following expressions:

$$k = (V^2/\hbar)\,(4\pi\lambda / k_B T)^{1/2} \exp(-\beta E_a), \qquad \text{(B4.2)}$$

where V is the nonadiabatic coupling between the two surfaces (determined by the nuclear coordinates). The activation energy E_a has the following well-known form:

$$E_a = (\Delta G^0 + \lambda)^2 / 4\lambda, \qquad \text{(B4.3)}$$

where ΔG^0 is the free energy gap and λ is the solvent reorganization energy. In Figure B4.1 we show the potential energy surface to explain the notation.

In the adiabatic limit, the rate expression is different and is given by

$$k = \frac{\omega_R}{2\pi} \exp(-\beta E_a), \qquad \text{(B4.4)}$$

where ω_R is the harmonic frequency of the reactant well.

The above expressions are essentially transition state expressions. The important thing to note is the parabolic trend of the rate predicted by equation (B4.3) as a function of the free-energy gap ΔG^0.

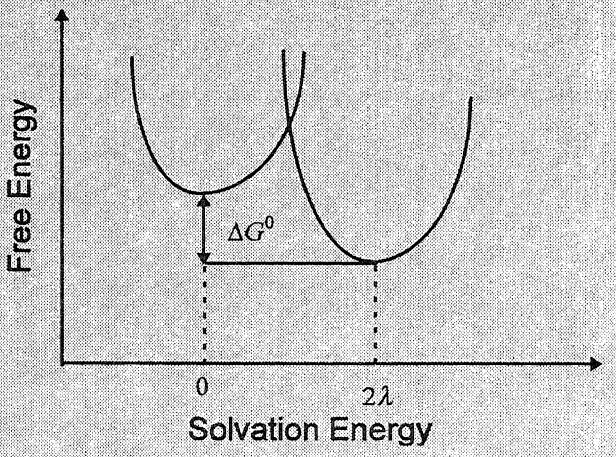


Figure B4.1. A schematic representation of the reaction free-energy surface, according to the Marcus theory. ΔG^0 is the free-energy gap between the reactant and the product and λ is the solvent reorganization energy. Note that the reaction coordinate (the abscissa) has been set to solvation energy.

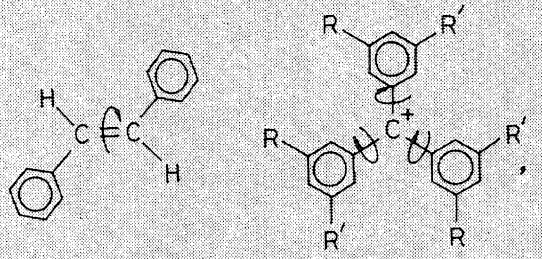
Since the reaction coordinate is the fluctuating energy gap due to solvation, it is obvious that solvation dynamics will play an important role in determining the dynamics of electron transfer. Zusman was the first to quantify this dependence by deriving the following expression for an adiabatic reaction:

$$k = \frac{1}{\tau_L}(16\pi k_B T/\lambda)^{-1/2} \exp(-\beta E_a), \qquad \text{(B4.5)}$$

where τ_L, the longitudinal relaxation time, is a measure of the solvation time of a newly created ion[1–10].

When the solvent polar response is ultrafast, like in water and acetonitrile, then the above expression for solvent effects undergoes significant modification. The theoretical work that accounts for ultrafast solvation is available in ref. 32. The main results are described in the text.



Another reason for the non-Marcus energy dependence is the involvement of high-frequency modes of the product state, which often serve as the accepting modes to accelerate electron transfer[37–39]. This mechanism is particularly useful when the electron transfer is in the Marcus inverted regime and results in the absence of the decrease of the rate as the free-energy change between the reactant and the product is made larger (that is, G is negative and large). This mechanism of the non-Marcus energy gap dependence seems to be responsible for the large electron transfer rate observed recently in betaines[38].

Isomerization dynamics

Isomerization reactions are very important chemical reactions. There are several reasons why these reactions often proceed at a very high speed. First, no chemical bond is broken or formed. The barrier is often rather small, only a few kcal/mol[43]. Moreover, there are several important reactions which proceed in the absence of any activation barrier. Some examples are the *cis* → *trans* isomerization of excited stilbene and also the isomerization of triphenyl methane dyes, such as malachite green[43]. These reactions are naturally very

Box 5.

There are two classes of molecules which are particularly useful in the study of isomerization dynamics. These are stilbenes and the triphenyl methane dyes. The structures are shown below:

R, R′ = alkyl group

The reactive motion, in each case, is a twist of a group around a body-fixed axis, as shown by the arrows. The isomerization reaction is a high-barrier one for *trans* → *cis* isomerization in stilbene, but nearly barrierless for *cis* → *trans* for the same system. It is also barrierless in a large number of TPM dyes, like crystal violet and Malachite green.

Experimentally, these molecules are often studied by exciting them to a higher electronic state. The dynamics of isomerization is then studied by monitoring the decay of fluorescence from these dyes. Since isomerization leads to the formation of a new state, the fluorescence from the reactant gets quenched as the reaction proceeds. Thus, the time dependence of the decay of fluorescence intensity serves as an excellent probe of isomerization dynamics. The experiments have usually concentrated on the temperature and viscosity dependence – the latter often shows very interesting fractional viscosity dependence. However, the latter problem, despite considerable effort over the last two decades, has remained largely ill-understood. This is because the potential energy surfaces of isomerization reactions appear to be rather sensitive to their environment. For example, the activation energies change significantly when the solvent is changed. Even the change of temperature affects the activation energy because the properties of the solvent often change significantly with temperature. This is also true, perhaps to a lesser extent, for pressure change. Thus, one is left with very limited scope for changing the viscosity of the solvent without affecting the reaction potential energy surface. Thus, computer simulations appear to be the ideal method to bridge the gap between theory and experiments.

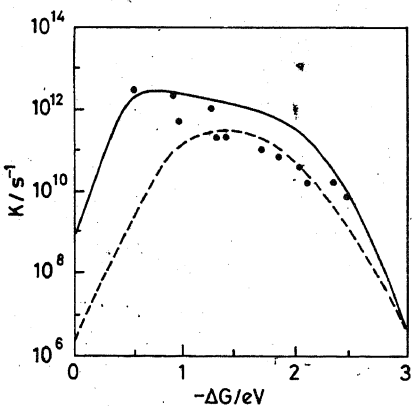


Figure 5. Breakdown of the Marcus parabolic dependence on the free-energy gap for charge recombination in newly formed contact ion pair. The black circles denote the experimental results of Asahi and Mataga[36] while the solid line is the theoretical prediction of Murata and Tachiya[40]. The Marcus parabola is also shown by the dashed line.

fast. There are some cases also where the barrier is significant. In other words, the isomerization reactions span a diverse range in kinetic behaviour. Because of the simplicity of these reactions, they serve as the testing grounds for the theoretical models of solvent effects. We shall discuss here two important and recent theoretical developments which were initially motivated by experimental results on ultrafast isomerization reactions in solution but led to far-reaching consequences (Box 5).

Before 1980, the effects of solvent viscosity on isomerization reaction were explained by using the well-known Kramers' theory[44]. This theory assumes that a chemical reaction can be viewed as the passage of a Brownian particle over an activation barrier. For large solvent viscosities, this theory predicts that the rate is inversely proportional to the viscosity. This is a straightforward consequence of modelling the reaction as a Brownian motion. Initial experiments seemed to have supported this. Detailed experimental studies could be undertaken only after picosecond laser became available in the early eighties. The new experimental results clearly indicated that for fast isomerization reactions (with lifetimes in the picosecond and even in the subpicosecond range) in solution, Kramers' theory was inadequate to explain the viscosity dependence – the observed viscosity dependence was much weaker than the inverse dependence predicted by Kramers' theory[45–47].

Box 6.

The recent experimental results from the study of isomerization dynamics have played a key role in the development of modern chemical reaction theory. Not only did these results motivate newer studies, but they also serve as the testing ground for the older theories. Here we discuss one particular class of theories which have been quite successful in explaining the viscosity dependence of the rates. Prior to 1980, the only theoretical framework available in this area was that due to Kramers, who modelled a chemical reaction as the motion of a solute in a one-dimensional double well potential. The reaction occurs when the solute escapes from one well to the other and in the process needs to go over the potential barrier, which is modelled as an inverted parabola of frequency ω_b. Kramers assumed that the equation of motion was an ordinary Fokker–Planck equation. This second-order partial differential equation could be solved for the steady-state solution, which gives the following expression for the rate:

$$k = \frac{\omega_R}{2\pi\omega_b}\left[\left(\frac{\zeta^2}{4}+\omega_b^2\right)^{1/2}-\frac{\zeta}{2}\right]\exp(-\beta E_a), \quad \text{(B6.1)}$$

where E_a is the activation energy, ω_R and ω_b are the harmonic frequencies of the reactant well and of the barrier top, respectively. ζ is the friction on the reactant motion. For isomerization reaction, this friction may be proportional to the viscosity of the solvent. Kramers' expression predicts that at high viscosities (that is, larger than 10 cP), the rate should be proportional to viscosity. However, experiments indicate that for many reactions with high barrier, the rates show a much weaker (such as, fractional) viscosity dependence. In 1980, Grote and Hynes[49] presented a generalization of Kramers' theory. These authors pointed out that Kramers' theory may be inadequate because it neglects the memory of motion along the reaction coordinate. The generalized rate is obtained by solving the following relation self-consistently:

$$\lambda_r = \frac{\omega_b^2}{\lambda_r + \hat{\zeta}(\lambda_r)}, \quad \text{(B6.2)}$$

where the factor λ_r gives the required rate by $k = \lambda_r k^{TST}$, k^{TST} being the transition state rate. In the above equation, $\hat{\zeta}(x)$ is the frequency-dependent friction, which gives the viscoelastic response of the solvent. As explained in the text, a reaction with a sharp barrier can probe only the high-frequency component of friction, which can be vastly different and much smaller than the zero-frequency friction that enters in Kramers' theory. This can explain the weak viscosity dependence of rate in many isomerization reactions. However, as described in Box 5, experimental difficulties have not yet allowed a full, convincing comparison between theoretical predictions and the experiments.

This started a flurry of theoretical activity[48–51]. Interestingly, the work that proved to be the most useful in this stage was published only a few years ago by Grote and Hynes[49]. The understanding that has emerged is the following. In *cis* ↔ *trans* isomerization reactions, the two potential energy minima are often separated by a dihedral angle lying between 90° and 180°. This gives rise to a sharp barrier when the activation energy barrier is somewhat larger than 10 kcal/mol. A sharp activation barrier implies that the reactant spends very little time in the barrier region and, therefore, probes only the high-frequency part of the solvent frictional response. The relation between the barrier height and the barrier curvature has been illustrated in Figure 6. This is to be contrasted with Kramers' theory, which assumes a slow diffusive motion along the reaction coordinate across the barrier (Box 6). For a sharp barrier only the former picture is valid. Since at large viscosities the high-frequency frictional response of the liquid gets decoupled from the macroscopic (that is, zero frequency) viscosity, the reaction rate also gets decoupled from viscosity and this shows up as a weak dependence of the reaction rate on the solvent viscosity. This rather elegant explanation is also known as the non-Markovian effect in barrier crossing.

Another class of isomerization reaction has drawn attention in the recent years[43, 52–54]. This is the zero-barrier reaction limit. As already mentioned, several important photochemical reactions fall in this limit. Consider that a molecule is optically excited and that in the excited state there is a photochemical funnel at the minimum of the excited-state surface. The motion that takes the system from its initial state to the final state is the reactive motion. The situation is depicted in Figure 7. This reactive motion can be the rotation of a bulky, molecular group (as in the case of TPM dyes). In this case the rate of reaction can be very high and dependent on the solvent viscosity. For *cis* → *trans* isomerization of stilbene in hexane, the isomerization rate seems to be as high as 10^{13} s^{-1} (refs. 53, 54). This is one of the fastest rates

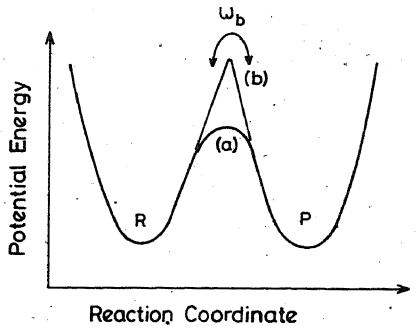

Figure 6. A schematic illustration of the dependence of the curvature of the activation barrier of the isomerization reaction on the barrier height. As the barrier height increases, the barrier frequency (ω_b) also increases, leading to the decoupling of the rate from the solvent viscosity.

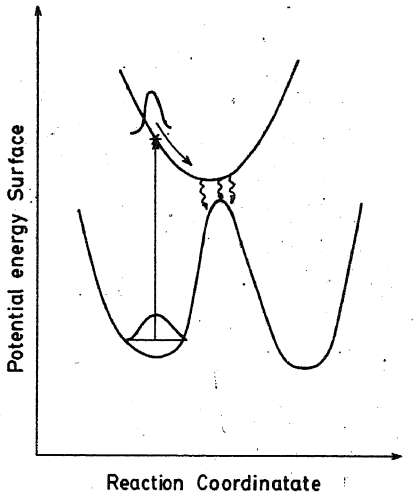

Figure 7. A schematic illustration of a zero-barrier chemical reaction. Initial excitation places the molecule in a nonequilibrium position on the excited-state potential energy surface. Subsequent relaxation brings the molecule to the potential minimum, where a photochemical funnel (or a sink) is present, This funnel gives rise to the decay of the excited state. The reactive motion is the relaxation from the initial excitation position to the configuration where the sink is located.

measured in the condensed phase. The decay of population on the excited state can often be measured by studying the disappearance of fluorescence from the excited state or by the recovery of the ground state population. An important characteristic of this type of reaction is that the time dependence of the excited-state population is highly nonexponential. Another important hallmark of barrierless reactions is the fractional viscosity dependence of the rate. The reason for the fractional viscosity dependence here is rather different from that in the high-barrier reaction and is often the multidimensional nature of the reaction potential energy surface; the second dimension may be a solvent mode or an intramolecular vibrational mode.

The theoretical studies of barrierless reactions are mostly based on a stochastic approach, where a Smoluchowski or a Fokker–Planck equation is used to describe the motion on the reaction potential energy surface with a coordinate-dependent sink term to account for the decay from the photochemical funnel. This approach[43] seems to have been fairly successful in describing the experimental results.

Ultrafast chemistry in biological processes

It should be pointed out that it is a fairly recent realization that the barrierless chemical reactions are quite common not only in chemistry but also in biological reactions. The most famous examples are the electron transfer in the reaction centre in photosynthesis[55] and the isomerization reaction in rhodpsin, which triggers the proton pump in the retinal membrane. These discoveries have led to very interesting chemistry. In what follows, we briefly discuss a very recent theoretical work by Chandler *et al.*[56] that led to valuable insight into the electron transfer mechanism in the photosynthetic reaction centre. A schematic representation of the relevant part of the reaction centre is shown in Figure 8. It is known that after the photoexcitation, the electron transfer takes place from 1 to 3 along the right-hand side of the figure. The theoretical work mentioned above has suggested that the reason for this selective transfer is that this reaction is barrierless while the $1 \rightarrow 2$ transfer involves a sizeable activation barrier[56]. A schematic drawing of this situation is shown in Figure 9. Another important example is the isomerization of bacteriorhodopsin in the retinal membrane, halobrium halobacterium. This is also a barrierless reaction with a time constant of 0.5 ps (refs. 57, 58). This reaction has recently raised a lot of interest. Yet another example of much current interest is the recombination of oxygen and carbon monoxide with the iron in heme in myoglobin[59, 60]. Flash photolysis studies have shown that this reaction follows a nonexponential kinetics. Interesting theoretical work has been done on this problem. Much experimental, computer simulation and theoretical studies have been done on the dynamics of proteins, which seem to have relaxation over a range of time scales. As the technique of ultrafast spectroscopy becomes more and more refined, we can look forward to many more fascinating applications of ultrafast chemistry to biological systems.

In the past many experts have raised the following question: What could be the relevance, if any at all, of the ultrafast chemistry to biology when the life processes occur on much slower time scales? This is certainly a valid question. With the recent discoveries of ultrafast biological processes (such as electron transfer in a photosynthetic reaction centre), this question needs to be reformulated as follows: Why does Nature use so

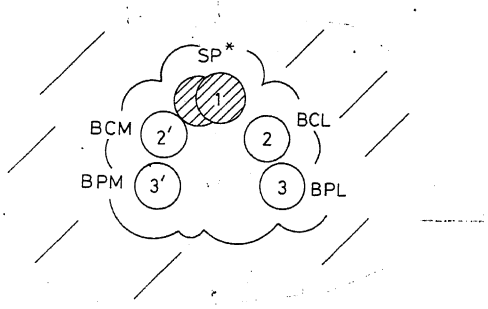

Figure 8. A schematic depiction of the essentials of the primary electron transfer event in a bacteria photosynthetic reaction centre. SP* denotes the photoexcited special pair. The electron, in principle, can be transferred either to the L branch, forming the charge-separated states SP^+ BCL^- or SP^+ BPL^-, or it can go to the M branch, forming similar states. The experimentally observed case is SP^+ BPL^-.

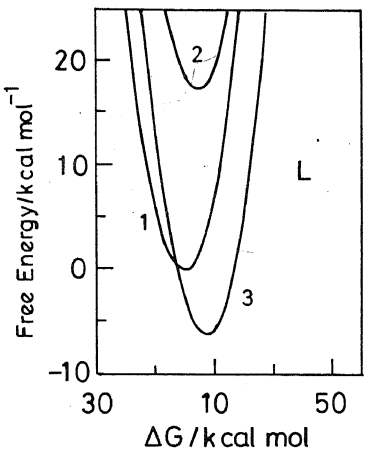

Figure 9. A schematic illustration of the explanation given by Chandler *et al.*[56] for the formation of SP^+ BPL^- (see Figure 8). Here the state SP* is the electronic state 1, SP^+ BCL^- is the electronic state 2 and SP^+ BCL^- is the electronic state 3. This figure shows the calculated Marcus free energy for the diabatic surfaces for all the three states. The electron transfer occurs from 1 to 3 because it is barrierless and energetically favourable. The transfer to M branch ($1 \rightarrow 3$) involves a sizeable activation barrier.

many different time scales in biological functioning? Qualitatively, the answer to this apparently profound question is simple enough: the dynamical processes at different time scales are hierarchially coupled. An extreme example of this coupling is provided by diffusion in the supercooled liquid. Here the rapid rattling motion of a molecule in the cage formed by its neighbours is ultimately responsible for the rare jumps or hops that give rise to the diffusive mass transport. The time scales of these two motions differ by many orders of magnitude, but the slow motion would be impossible without the former. Perhaps the reason that Nature uses so many different time scales, from ultrafast to ultraslow – often separated by several orders of magnitude – is to minimize the scope of making mistakes. This is probably developed by natural selection over many years.

Conclusion

With the advancement of ultrafast spectroscopy in the last decade, many important discoveries have been made which have helped in solving some long-standing puzzles in chemistry and biology. For example, one was puzzled by the absence of dynamic solvent effects on various charge transfer reactions in water. The paradox was partly due to the known result that the dielectric relaxation in water is about 9 ps, which is quite long. Only last year was it discovered that solvation dynamics in water is more than two orders of magnitude faster. This explains why we do not see the above-mentioned solvent dynamic effects in water. Similarly, the recent understanding of electron transfer reactions, especially the involvement of the high-frequency vibrational modes, has also emerged only in the last five years and again the impetus came from the discovery of novel aspects by using ultrafast spectroscopy. With the availability of femtosecond lasers in many laboratories around the world, we can look forward to many more such interesting discoveries in the near future.

Membrane current and potential change during neurotransmission in smooth muscle

Rohit Manchanda

School of Biomedical Engineering, Indian Institute of Technology, Powai, Bombay 400 076, India

Smooth muscle cells are electrically coupled to one another in a syncytium, and this renders their electrophysiology during neurotransmission strikingly different from that at other synapses. The postjunctional depolarizing responses of sympathetically innervated smooth muscle such as the vas deferens, particularly, the excitatory junction potentials (EJPs), possess intriguing properties which for several years have resisted explanation. A principal issue has been the temporal relationship of transmitter-generated membrane current to the resulting potential change, which seems to differ depending upon whether transmitter release is spontaneous or is nerve-stimulation-evoked. Accordingly, smooth muscle electrical properties appear to change with different patterns of transmitter release. Until some years ago this relationship was an area of uncertainty, firstly because transmitter-activated membrane current could not be measured directly and secondly because intracellular membrane potential measurements gave rise to conflicting results. Many of the uncertainties have now been resolved with refinements in techniques of measurement that have allowed membrane current time course during neurotransmission to be estimated. As a result, our understanding of smooth muscle electrical properties has been clarified and deepened. These developments are outlined in this review, and it is shown how our comprehension of neurotransmission has at every stage been influenced strongly by the techniques adopted for investigation.

THE electrophysiology of neurotransmission from autonomic nerves to smooth muscle has consistently been more challenging to study than somatic neuromuscular transmission. To a large extent this owes to the technical difficulties involved in making electrical recordings from smooth muscles. It is relatively problematic to record intracellularly from individual smooth muscle cells, which are just 2–5 μm in diameter, in contrast to skeletal muscle cells, whose diameters can be 50–150 μm. One requires to use microelectrodes with very small tip diameter (≤ 0.2 μm) and high tip impedance (50–200 MΩ). Further, when operating at these submicroscopic ranges the recording apparatus is exquisitely sensitive to mechanical vibration. Finally, when recordings are obtained their interpretation in terms of tissue electrical properties often rests on uncertain ground. This is because smooth muscle, as outlined below, is a complex electrical syncytium with cells interconnected to one another in three dimensions[1,2], and their electrical properties are poorly understood. Hence, even the primary depolarizing electrical responses of smooth muscles during neurotransmission, the excitatory junction potentials (EJPs), are not satisfactorily understood. In many cases these responses continue to be explored at the phenomenological rather than at the analytical level. By contrast, the processes involved in transmission at skeletal muscle have been rather thoroughly elaborated[3,4], starting from the end-plate potential down to the gating properties of the transmitter-activated receptor–ion-channel complex and the explanation of the end-plate currents in terms of channel function[5,6]. However, in recent years considerable progress has been made in our understanding of the generation of smooth muscle EJPs as well as the membrane currents underlying them. Some of this owes to the application of novel electrical recording methods to smooth muscle[7,8], and some to theoretical work. Several interesting observations and hypotheses have arisen, and it will be the aim of this article to review these developments. To set them in context, the historical development of ideas on the electrical properties of smooth muscles during neurotransmission will first be outlined. This will include a discussion of the 'cable' properties of smooth muscle, and the factors determining current spread and membrane potential development during EJPs. Since the field is now quite extensive, attention will centre on the properties of sympathetically innervated smooth muscle, particularly the vas deferens, which today provides an interesting and fruitful territory of research. Action potentials in smooth muscles will not be discussed, arising as they do subsequent to junctional transmission. For a survey of this topic the reader is referred to the detailed reviews of Tomita[2] and Huizinga[9].

Syncytial nature of smooth muscle and its innervation

Smooth muscle cells are well known to be electrically interconnected to one another to form what is known as a 'three-dimensional syncytium'[10–14]. Bozler[15] in 1948 was the first to suggest the syncytial nature of smooth muscle. His hypothesis was validated by the demonstration that injected current can flow, and membrane potential changes can be recorded, along smooth muscle tissues over distances which are considerably greater than the average individual cell length. The spread of current and potential occurs presumably through intercellular pathways of low resistance[2,10,16,17]. The syncytial organization of smooth muscle cells renders their electrophysiology in many respects different to that of other kinds of cells, e.g. skeletal muscle fibres, which are electrically isolated from their neighbours.

a. Autonomic–smooth muscle *b*. Somatic–skeletal muscle

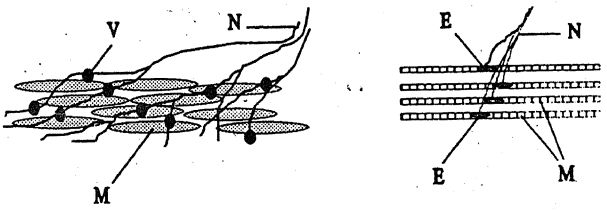

Figure 1. Comparison of patterns of innervation at the autonomic (*a*) and skeletal (*b*) neuromuscular junctions. N: nerve fibre; M: muscle cell; E: end-plate; V: varicosity. Smooth muscle cells are shown relatively shortened in length (e.g. in relation to varicosity diameter) for illustration.

The pattern of innervation of smooth muscle by autonomic nerves also differs from that of skeletal muscle by somatic nerves. As shown in Figure 1 *a*, the innervation of many smooth muscle organs is of the 'distributed' kind, that is, each cell may receive input from varicosities on more than one terminal nerve fibre and any terminal fibre may innervate several cells[14]. The result is a mesh of innervation known as the 'autonomic ground plexus', varicose in appearance, in which the points of transmission are thought to be the periodic axonal swellings, the varicosities. Some cells are innervated closely by the varicosities (contact distance < 20 μm) and others not[14,18]. In contrast to this meshwork, each skeletal muscle fibre receives a well-defined, localized innervation from a somatic motoneurone that forms a discrete 'end-plate' (Figure 1 *b*) where neurotransmission occurs[3–5]. Each skeletal muscle fibre is supplied by the terminal branch of only one somatic motor axon, and usually has just one end-plate.

As a consequence of the electrical interconnections between smooth muscle cells and of their complex innervation, any membrane potential change (such as an EJP) recorded in a particular cell will reflect not simply the response of that cell alone, but also the response, passively propagated to it, of neighbouring cells. Spatial and temporal summation of its own response may occur with the responses of neighbouring cells[11]. The extent of this 'pick-up' will depend largely on the electrical prop-

erties of the interconnecting pathways between the cells. For these reasons it is problematic to analyse electrical events at the level of individual smooth muscle cells in the kind of detail that has characterized the investigation of skeletal muscle, in which the electrical responses of an individual muscle fibre are independent of the responses of neighbouring cells.

Passive electrical properties

The passive electrical properties of a cell or a tissue, such as its membrane resistance and capacitance, and its length and time constants, are important determinants of the electrical response of the cell to any given input, since they determine its impulse response[19–21]. Thus, the amplitude, time course and spatial spread of a junction potential – be it the EPP in skeletal muscle, the excitatory or inhibitory postsynaptic potentials in neurones, or an EJP in smooth muscle, all of which are produced by neurotransmitter-activated transmembrane current – will depend largely on the passive properties. So will action potential properties such as conduction velocity[22,23].

Junction potentials usually have relatively rapid rising phases and slower, usually exponentially decaying, falling phases (Figure 2 *a*). In many kinds of cells the falling phase of the junction potential decays with a time constant that is equal to the cell's membrane time constant, τ_m. This indicates that the junction potential decay is a purely passive electrical process. The active part of the process, i.e. the neurotransmitter-activated membrane current, is relatively brief. Its duration is often of the order of the rise time of the junction potential (Figure 2 *b*). Transmitter-activated membrane current serves to discharge the membrane capacity and produce the rising phase of the junction potential, with the subsequent decay of the potential following the time course of passive recharging of the membrane capacity, at a rate determined by τ_m (refs. 5, 24). Thus, the time constant of decay, τ_{decay}, of the junction potential equals τ_m (Figure 2).

These properties are in many respects similar to those of potential changes across the capacitor in a parallel resistance–capacitance circuit in response to the flow of current through it. Based on this general principle, a standard method of evaluating the factors governing the time course of a junction potential has been to estimate τ_m and compare it with τ_{decay} of the junction potential. If the two values are similar, then the membrane currents and potential are held to behave as outlined above. If τ_{decay} exceeds τ_m, other factors – such as a duration of transmitter action greater than τ_m – have to be considered[25].

An approach such as this should in principle have revealed readily the elements of junctional processes in smooth muscle. As ever, though, smooth muscle presents bedevilling complications. One is that in a

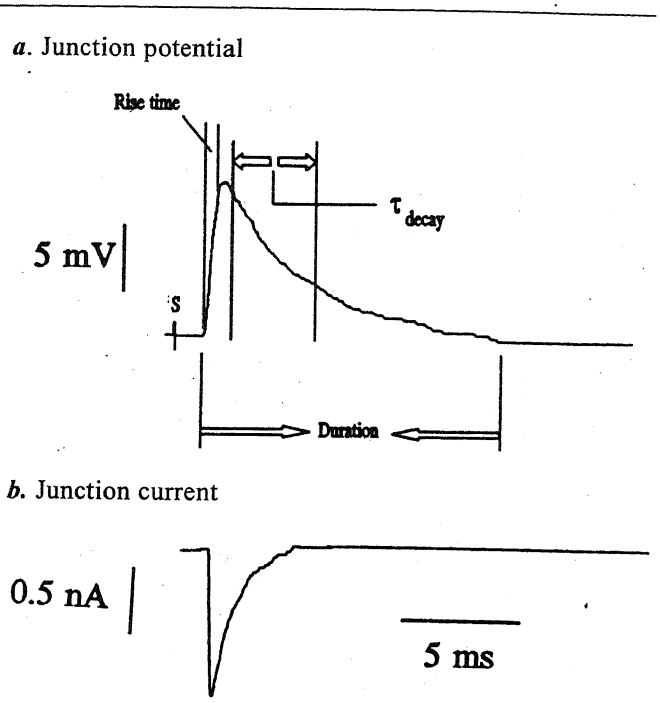

Figure 2. A typical junction potential (*a*) and its underlying junction current (*b*) as observed at a variety of synapses. S: stimulation artefact. Parameters of analytical interest are indicated. Note that membrane potential change is prolonged compared to membrane current, because of the capacitive properties of the cell membrane. The downward current trace indicates inward membrane current. Typical amplitudes and time courses observed at the skeletal neuromuscular junction are indicated by the calibration bars; however (as will be seen in subsequent figures), values may vary depending upon the cell type under investigation. It should also be noted that if junction current time course were measured using extracellular recording, its amplitude calibration would be in volts rather than in amperes.

syncytium, τ_m itself varies under different conditions of determination. The estimation of τ_m in simpler structures (those approximating linear one-dimensional cables, such as skeletal muscle fibres and axons) has been relatively straightforward. One injects rectangular pulses of constant current at a point inside the cable and measures the resulting membrane potential changes (the subthreshold or electrotonic responses) at increasing distances from the point of injection[3,5]. τ_m, and other passive parameters such as membrane resistance, capacitance and length constant, λ_m, can then be evaluated using the well-known properties of the cable equation[21].

By contrast, current injection at a point in the smooth muscle syncytium (i.e. intracellularly in a single cell) results in no detectable membrane potential change even in its immediate vicinity[11,26]. The reason for this is thought to be a very rapid spatial dissipation of injected current through the multiple shunts offered by intercellular electrical pathways in three dimensions, so that no appreciable fraction of it flows to any neighbouring area. Thus, smooth muscle does not exhibit cable properties with intracellular current injection. However, when it is subjected to current injection through large

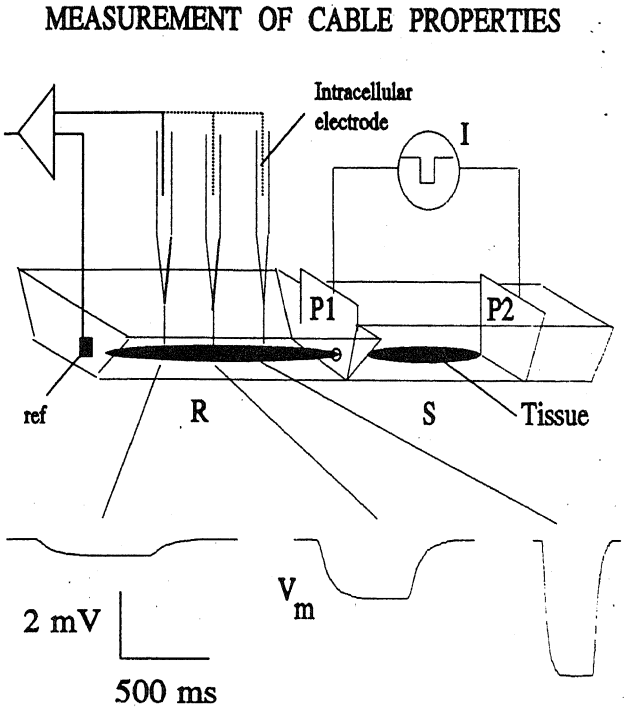

Figure 3. Partition stimulation chamber used for investigation of smooth muscle cable properties. R: recording chamber; S: stimulating chamber; P1, P2: metal plates for stimulation and partition; I: current source; V_m: membrane potential change at different distances from plate P1, recorded intracellularly (with reference to indifferent electrode 'ref'). The scale is exaggerated: V_m responses may be recorded up to only a few mm from P1. Also there would be a tight fit between the tissue and the hole in P1. Amplitude and time scales are appropriate for guinea pig vas deferens. Adapted from ref. 16.

extracellular electrodes, smooth muscle does, surprisingly, start to exhibit cable properties, so that membrane potential changes are recorded at a distance from the area of current injection. Particular mention may be made of the 'partition stimulation' method first employed by Tomita[10,11] and Abe and Tomita[16]. The experimental arrangement is shown in Figure 3. The cylindrical smooth muscle organ is drawn through a circular hole of matching diameter in a metallic plate (P1) which forms a plane at right angles to the longitudinal axis of the tissue. The plate also separates the organ bath in which the tissue is placed into two compartments electrically insulated from each other. Current is passed extracellularly between this plate and another plate electrode (P2) in the stimulating compartment (S), while in the recording compartment (R) membrane potential responses are measured intracellularly. As shown in Figure 3, passive (electrotonic) responses can now be detected in tissue cells up to a few millimetres from the plate, and a quantitative evaluation of these responses indicates that the organ now behaves as a one-dimensional cable. An explanation for this change of properties is that when external plate electrodes are used to polarize the smooth muscle cells, the tissue is rendered more or less isopotential in its two radial axes at the stimulation plate. Hence, injected current can only spread in one direction – along the longitudinal aspect of the tissue – and the tissue acquires cable-like properties in this direction[10,11,17]. Some of these properties are: (i) the peak values of the membrane potential responses to external stimulation decay exponentially with distance from the polarizing plate; (ii) the temporal properties of the membrane potential changes at different distances can be described by linear one-dimensional cable equations.

The electrotonic responses thus measured can be used to estimate passive electrical properties such as length constant and time constant of the tissue[11,27]. In the case illustrated (hyperpolarizing current injection) the change of membrane potential (V_m) with respect to both time (t) and distance (x) is given by[16,19]

$$V_m(X,T) = V_m(X=0, T=\infty)\frac{1}{2}\left\{e^{-X}\left[1+\mathrm{erf}\left(\frac{X}{2\sqrt{T}}-\sqrt{T}\right)\right] + e^{X}\left[1-\mathrm{erf}\left(\frac{X}{2\sqrt{T}}+\sqrt{T}\right)\right]\right\}, \quad (1)$$

where $X = x/\lambda_m$ (here $0 < X < \infty$) and $T = t/\tau_m$, x being the distance from the stimulating electrode and t the time from start of stimulation; erf is the error function, defined as

$$\mathrm{erf}(y) = \frac{1}{2\sqrt{\pi}}\int_0^y e^{-\omega^2}\,d\omega. \quad (2)$$

By comparing the prediction of equation (1) with the observed responses, one can verify the correctness of the values of the length constant and time constant obtained experimentally, and thus estimate the passive membrane properties.

Based on the responses to intracellular and extracellular polarization, various suggestions, often conflicting, have been made about the factors determining the time courses of EJPs, and the relationship of membrane potential change to membrane current, in smooth muscle. These hypotheses are reviewed below.

Smooth muscle junction potentials and their analysis

Two kinds of excitatory potentials are recorded at the synapse between the terminals of the vas deferens nerve postganglionic to the hypogastric nerve and the smooth muscle cells of the vas[28,29]: the evoked and spontaneously occurring junction potentials (the EJP and SEJP, respectively, Figure 4 *a*). EJPs and SEJPs have been recorded in several autonomically innervated smooth muscles, but the most detailed work has been done on junction potentials at the sympathetic neuroeffector junction, particularly in the rodent vas deferens, and in arteries and arterioles.

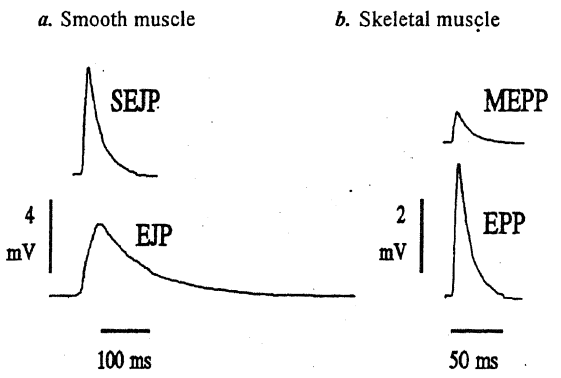

Figure 4. Spontaneous and stimulation-evoked junction potentials seen in smooth (*a*) and skeletal (*b*) muscle. Spontaneous potentials: SEJP, MEPP. Evoked: EJP, EPP. In smooth muscle the SEJP is briefer than the EJP but can be as large as the EJP. In skeletal muscle the MEPP follows the same time course as the EPP but has a smaller amplitude. Note the different time scales in *a* and *b*.

The SEJP occurs in the absence of nerve stimulation and is thought to be caused by the spontaneous release of a quantum of transmitter from a neuronal varicosity. The EJP, on the other hand, is a stimulation-evoked event and is thought to be caused by the release of transmitter throughout the neuronal ground plexus following nerve stimulation[30,31]. Qualitatively, these responses are analogous to the miniature and the stimulation-evoked end-plate potentials (MEPPs and EPPs) observed at the skeletal neuromuscular junction, produced, respectively, by the release of one quantum of transmitter (spontaneously) or of several quanta (following nerve stimulation)[32] (Figure 4 *b*). However, there are important differences, as illustrated in Figure 4. In relation to time courses the most striking one is that whereas the MEPP and the EPP have similar time courses (Figure 4 *b*), the SEJP and the EJP differ by a factor of 5–10 in theirs, the SEJP being briefer[28,33] (Figure 4 *a*). SEJPs usually have durations of 100–150 ms and τ_{decay} of 20–50 ms, whereas EJPs have durations of 0.6–1 s and τ_{decay} ranges from 200 to 400 ms.

Another difference lies in relative amplitudes. Skeletal muscle MEPPs have amplitudes that are normally distributed about the range 0.5–1 mV, and the EPP amplitude is an integral multiple of this quantal level; EPPs are thus always as large as, and normally much larger than, MEPPs[32]. By contrast, in smooth muscle both EJP and SEJP amplitudes are continuously variable from the lowest to the highest levels (0–30 mV), EJP amplitude being graded with stimulation intensity and SEJP amplitudes varying randomly. There is no obvious quantal relationship between the two events, and SEJPs can often be larger than EJPs[28,33] (Figure 4).

Since MEPPs and EPPs have similar time courses, it would appear that the passive electrical properties of skeletal muscle cells remain invariant regardless of whether transmitter release is spontaneous or stimulation-evoked. However, in smooth muscle cells, since the SEJP and EJP follow very different time courses, the passive properties appear to change depending upon the pattern of transmitter release, i.e. whether it is spontaneous and localized to a varicosity or is evoked by nerve stimulation and, therefore, involves several varicosities throughout the ground plexus[11,13].

Using the principle of comparison of τ_m with τ_{decay} of the junction potentials, the decays of the MEPP as well as of the EPP of skeletal muscle were shown to be determined by the passive properties of the skeletal muscle cell membrane. However, in initial studies the decays of the SEJP and EJP in the vas deferens were suggested by various workers to reflect not τ_m but the time course of membrane current, indicating a prolonged duration of action of transmitter at the autonomic neuroeffector junction.

Experimental studies

The SEJP. For the SEJP, evidence for prolonged transmitter action came mostly from studies on membrane potential responses to intracellular stimulation. If the SEJP results from localized transmitter action at a point in a three-dimensional syncytium, then the electrical properties of the smooth muscle membrane during intracellular current injection may be assumed to reflect its properties during an SEJP. A number of workers[11,34–36] have studied the membrane potential responses of smooth muscle cells to intracellular current injection with current-passing microelectrodes. In the guinea pig and mouse vas deferens this response was usually observed to have a time constant of 2–7 ms, which is up to an order of magnitude higher than the time constant of decay of the SEJP (range 20–35 ms). It could even be more rapid than the rising phase of the SEJP, which occupies between 5 and 15 ms.

Thus, the time constant of the membrane in response to local application of current in the syncytium was much too brief to account for the time constant of decay of the SEJP. This excluded the possibility that the passive membrane properties of the vas deferens determined the decay of the SEJP. Hence, for the SEJP it was concluded that transmitter action might continue throughout its duration[10,11].

The EJP. Suggestions about the factors governing EJP time course came primarily from estimation of smooth muscle passive properties using the partition–stimulation method. From the passive responses described by equation (1), Tomita[11] estimated the length constant (λ_m) of the tissue to be about 1.5–2.5 mm. The membrane time constant τ_m of the smooth muscle cells was estimated to be about 100 ms.

The time constant of the declining phase of the EJP (200–400 ms) is significantly greater than this value of τ_m. Hence, it appeared that τ_m was too brief to account for the falling phase of the EJP, rather like the relationship of τ_m during intracellular polarization in relation to the SEJP. It was concluded[11,17,26] that the EJP too might reflect the time course of ongoing transmitter action rather than that of the passive recharging of the membrane capacity.

Thus, until the mid-1970s there seemed to be a consensus that transmitter-activated membrane current during both the SEJP and the EJP might persist throughout the duration of each category of junction potential. This contrasted with the brief time course of membrane current underlying the MEPP and the EPP at the skeletal end-plate. In the last 10–15 years, however, much evidence has been presented which suggests a somewhat different picture for the EJP. Let us consider these developments.

The most pertinent experimental analysis is that of Bywater and Taylor[27], who reinvestigated the passive electrical properties of the guinea pig vas deferens. They showed that the estimation of membrane time constant depended critically on the respective lengths of the tissues placed in the recording and stimulating compartments of the partitioned chamber. In particular, the calculated time constant was shown to be a considerable underestimate of its true value if less than three length constants of the tissue were placed in the stimulating compartment.

Obviating these sources of error, τ_m was estimated[27] with external polarization to be about 270 ms, a value significantly different from the previous estimate (100 ms)[11]. The length constant λ_m (~860 μm) was also shown to be smaller than the earlier estimate[11] of 1500–2600 μm.

Unlike the earlier value, the new estimate of τ_m coincided with the time constant of decay of the EJPs in the guinea pig vas deferens. The decay of the EJP, therefore, appeared to be dictated by the passive membrane properties of the smooth muscle cells. This would indicate a brief duration of transmitter-activated current underlying the EJP. Blakeley and Cunnane[30] and Bywater and Taylor[27] suggested that transmitter action underlying both spontaneous and evoked junction potentials corresponded in duration to the SEJP.

Theoretical studies

Smooth muscle syncytial properties have also been investigated from a theoretical standpoint[10,11,13]. It was shown that if current were injected from a point source into the syncytium (as for the SEJP) then, because of intercellular electrical coupling, the current would dissipate away from the point of injection very rapidly, both spatially as well as temporally[11]. As a result, the time course of the membrane potential change at or near the point of current injection would be similar to that of the current itself. On the other hand, when current of the same time course is injected uniformly throughout the syncytium (as for the EJP), spread of current is restricted and the potential change that develops then is prolonged, lagging considerably behind the current[13].

Purves[13] obtained the time course of the EJP by convolving the impulse response, $h(T)$, of an isopotential circuit with the input, the transmitter-activated current $I(T)$:

$$h(T) = \frac{Q_0}{c_m} e^{-T}, \tag{3}$$

$$I(T) = \alpha^2 T \exp(-\alpha T), \tag{4}$$

where Q_0 is the charge deposited instantaneously on, and c_m the membrane capacity of, unit volume of tissue, T is the normalized time (t/τ_m) and α is a driving function which, as used in equation (4), generates waveforms very similar in shape to synaptic currents observed at a variety of synapses[13,23]. Then the membrane potential response $V(T)$ is given by $V(T) = h(T)*I(T)$, the asterisk indicating the convolution operation. On solving the convolution integral we get the essential part of $V(T)$ as

$$V(T) = \alpha^2 e^{-\alpha T}\left\{\frac{e^{T(\alpha-1)}-1}{(\alpha-1)^2} - \frac{T}{\alpha-1}\right\}. \tag{5}$$

On evaluation, $V(T)$, corresponding here to the EJP, turns out to be considerably prolonged compared to the injected current $I(T)$.

Purves[13] also derived an expression for the voltage change during the SEJP. In this case the impulse response $h(T)$ is given by

$$h(T) = \frac{Q_0 r_i}{8(\pi T)^{3/2}\lambda\tau} e^{[-(R^2/4T)-T]}, \tag{6}$$

r_i being the intracellular resistance per unit volume and R the normalized radial distance.

Equation (6) can be convolved with the expression for transmitter-produced membrane current (equation (3)) and the voltage response derived. It was shown that the resulting voltage change is much briefer than that predicted for the isopotential EJP and, in fact, follows closely the time course of the current itself[13]. Hence, this theoretical work indicated that whereas the EJP is prolonged compared with its underlying membrane current, the SEJP follows the time course of the current.

Recent investigations

The foregoing conclusions can be unambiguously tested only by direct observation of the junction currents that underlie the potentials to establish the relationships between their time courses. One way to record junction

current is to perform a voltage clamp experiment, which has been done on several types of electrically isolated cells, including skeletal muscle fibres and neurones[4,24,37]. However, it is difficult normally to obtain an adequate voltage clamp of syncytial, three-dimensional tissues such as smooth muscle[38]. This is because, as previously described, smooth muscle cells have unsuitable geometries and are electrically interconnected.

Extracellular recording. A second convenient method of estimating membrane current time course is to record extracellularly the potential changes caused by the current sinks created focally at points of transmitter action[39]. Until the late 1980s this method could not be successfully applied to the autonomic-nerve–smooth-muscle junction because of technical problems[7,40,41]. However, in the past few years attempts at extracellular recording have been successful and, therefore, it has been possible to estimate the time course of membrane current underlying the EJPs[7,41–43]. The extracellular electrode used in the initial studies had a large tip diameter (20–50 μm) compared to the intracellular electrode, and was applied to the surface of the vas deferens with slight suction. This allowed the recording of negative-going extracellular potential changes of 20 μV and greater in amplitude. Since these events reflect the time course of membrane current, they were named excitatory junction currents (EJCs)[7].

Simultaneous intracellular and extracellular recordings of the time courses of junction potentials and currents have been obtained[8,33] and have given rise to some conclusive and interesting observations. In the experiments in which the spontaneous events were recorded, cells within a short distance (up to 100 μm) of the rim of the extracellular electrode were probed with the intracellular microelectrode[8,44]. This was necessary because, as mentioned above, the spatial decay of spontaneous potentials is very rapid and the same event could be detected with two electrodes only if they were very close to each other. The experiments unequivocally showed that when the same electrical event was recorded at both the electrodes[44], the time courses of the SEJP and the SEJC (i.e. the potential change and the current flow) were identical[8]. This is shown in Figure 5 for three pairs of SEJPs and their underlying SEJCs, and it is noteworthy that even for very different shapes of the events in Figure 5 *a*, *b* and *c*, potential change and current follow the same time course. The result strongly suggests that the membrane capacity is not charged significantly by the current induced by the action of a single quantum of transmitter, since if it were, membrane potential change would have lagged behind the current.

The nerve-stimulation-evoked EJP and the time course of its underlying EJC were also recorded simultaneously[8,33]. In this case it was observed that the membrane currents underlying the EJPs were brief, having

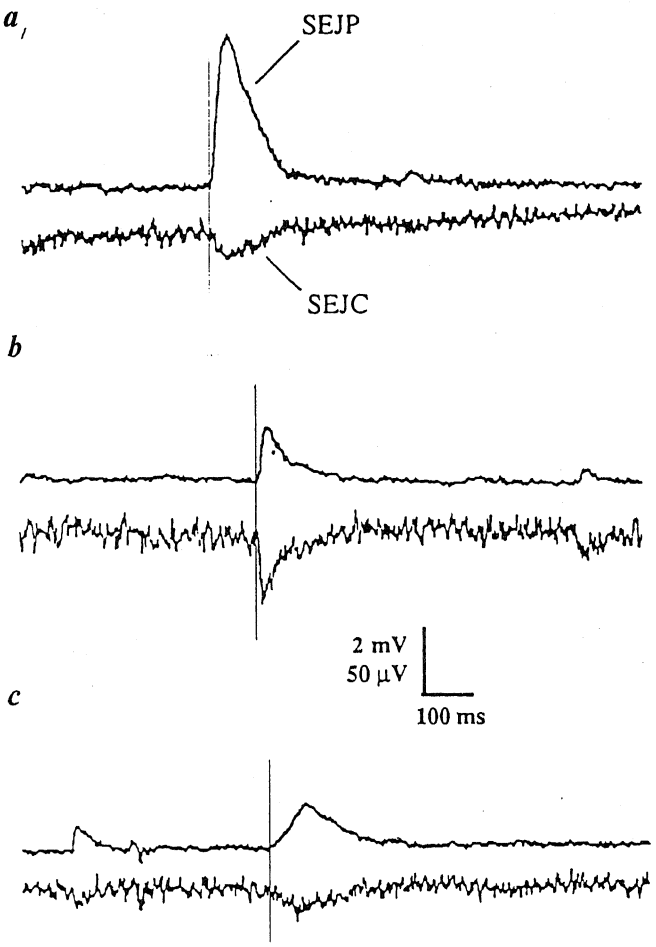

Figure 5. Spontaneous electrical events in smooth muscle (mouse vas deferens) recorded simultaneously with intracellular and extracellular electrodes (upper and lower traces, respectively, in *a*, *b* and *c*). Note the close correspondence between the time courses of membrane potential change (SEJP) and junctional current (SEJC) even for different shapes of the events: the almost linear decays in *a*, the biexponential decays in *b*, and the prolonged rise times in *c*. The reason for the somewhat distorted shapes is probably the mechanical pressure exerted by the extracellular electrode on the tissue[44]. Voltage scale: 2 mV for intracellular, 50 μV for extracellular traces.

durations (100–150 ms) and time constants of decay (25–40 ms) no greater than of the SEJCs (Figure 6). Hence, the prolonged time constant of decay of the EJPs (250–350 ms) cannot be attributed to prolonged transmitter action, owing, for instance, to slow inactivation or to physical barriers to diffusion[1]. It must instead be attributed to the passive decay of charge from the smooth muscle cells following spatially distributed injection of current into the tissue that changes it from a three-dimensional syncytium into one that is presumably at isopotential[13,33]. If this indeed is the case, the theoretical isopotential voltage response of the tissue (given by equation (5)) should predict successfully the experimental data. Evidence for this is presented in Figure 7. EJPs and EJCs were recorded simultaneously and 80 of each were averaged[33,44] (Figure 7 *a*). The EJC was

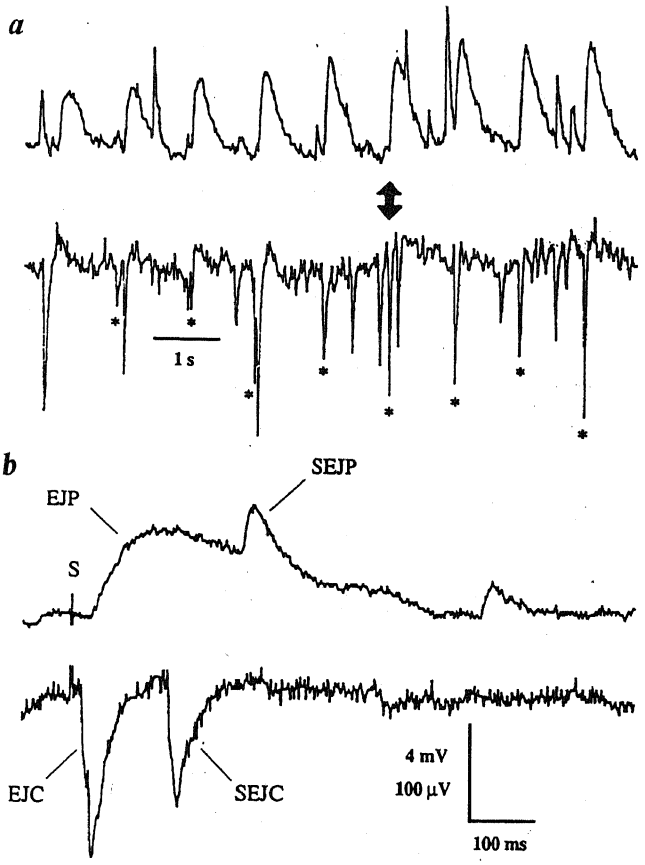

Figure 6. Stimulation-evoked electrical events in smooth muscle (guinea pig vas deferens) recorded simultaneously with intracellular and extracellular electrodes. A series of 9 EJPs is shown in *a*, the underlying EJCs marked with asterisks. In *b*, one of the paired events in *a* (marked with an arrow) is shown on an expanded time scale. Note the brief time course of the EJC compared to the EJP. Other deflections in *a* are spontaneously occurring SEJPs and SEJCs; one of each is indicated in *b*. Voltage scale: 4 mV for intracellular, 100 μV for extracellular traces. S: stimulation artefact.

shown to match the form of the theoretical junction current given by equation (3) (Figure 7 *b*). When this current was used as the input to an isopotential system and the voltage response computed, the response agreed very closely with the experimental EJP (Figure 7 *c*). In these recordings, therefore, the tissue appears to be at isopotential during the EJP[13,33]. In further support of this conclusion is the observation that under conditions of field stimulation of the tissue, the estimated membrane time constant of these cells (270–300 ms)[27] is very similar to the time constant of decay of the EJPs.

Bennett *et al.*[45] have carried out a theoretical analysis of the signals that one would expect to obtain with an extracellular surface electrode of the kind used in the studies mentioned above. Their predictions are in very good accord with the EJCs experimentally recorded earlier[8,41,43], and place confidence in the validity of the new measurements.

The quantal relation between the EJP and SEJP

Although the time courses of the SEJP and the EJP are widely different, the events have similar ranges of amplitudes, from just-discernible to threshold levels for action potential generation. The range of amplitudes of SEJPs can be explained by the effect of electrotonic decrement on events generated in a syncytium at varying radial distances from the recording electrode[11,13]. Events generated very close to the recording electrode are recorded as large SEJPs, and those at larger distances as smaller SEJPs. However, the EJP seems not to be composed of an integral multiple of SEJPs, as the quantal hypothesis in its simplest form (derived from the properties of the EPP and MEPP at the skeletal neuromuscular junction[32]) would suggest. This feature of sympathetic neurotransmission, by itself a separate important area of investigation, merits a brief comment. The problem here is that the EJP and the SEJP arise under different prevailing electrical conditions of the tissue (as detailed above). The EJP for most of its time course is a passive electrical event, and only its rising phase is actively determined by the underlying junction current (see Figures 6 and 7). So, a resolution of transmitter release events following nerve stimulation, and electrical identification of sites of release, would require investigation of its rising phase, in contrast to the decay phase, which throws light on the tissue's electrical properties.

Detailed examination of the rising phases of EJPs has revealed that they are not entirely smooth but are marked by inflexions, and that both the slope and the time of occurrence (latency) of these inflexions differ from one EJP to the next[30]. The first time differentials (dV/dt) of the rising phases, therefore, contain sharp peaks corresponding to the inflexions, and are termed 'discrete events' (DEs). DEs were postulated to be indications of the activity of individual transmitter release sites close to the recording electrode, the remainder of the EJP reflecting the background level of depolarization in the surrounding tissue. Rising phases of SEJPs were similarly differentiated to give rise to spontaneous DEs (SDEs).

Using DEs it has been possible to 'fingerprint' different release sites around the intracellular recording electrode by virtue of the differences in amplitudes, time courses and (for evoked events) latencies of the DEs[31]. Evidence from these studies suggests that stimulation-evoked release from an individual electrophysiologically identified release site (possibly a varicosity) is highly intermittent, and monoquantal. That is, in a train of stimuli, only one in several stimuli activate a particular release site. And when a site is activated, the resultant evoked DE corresponds exactly to a particular SDE observed in that cell[31]. It is not an integral multiple of the SDE. Thus, evoked release must be monoquantal if the

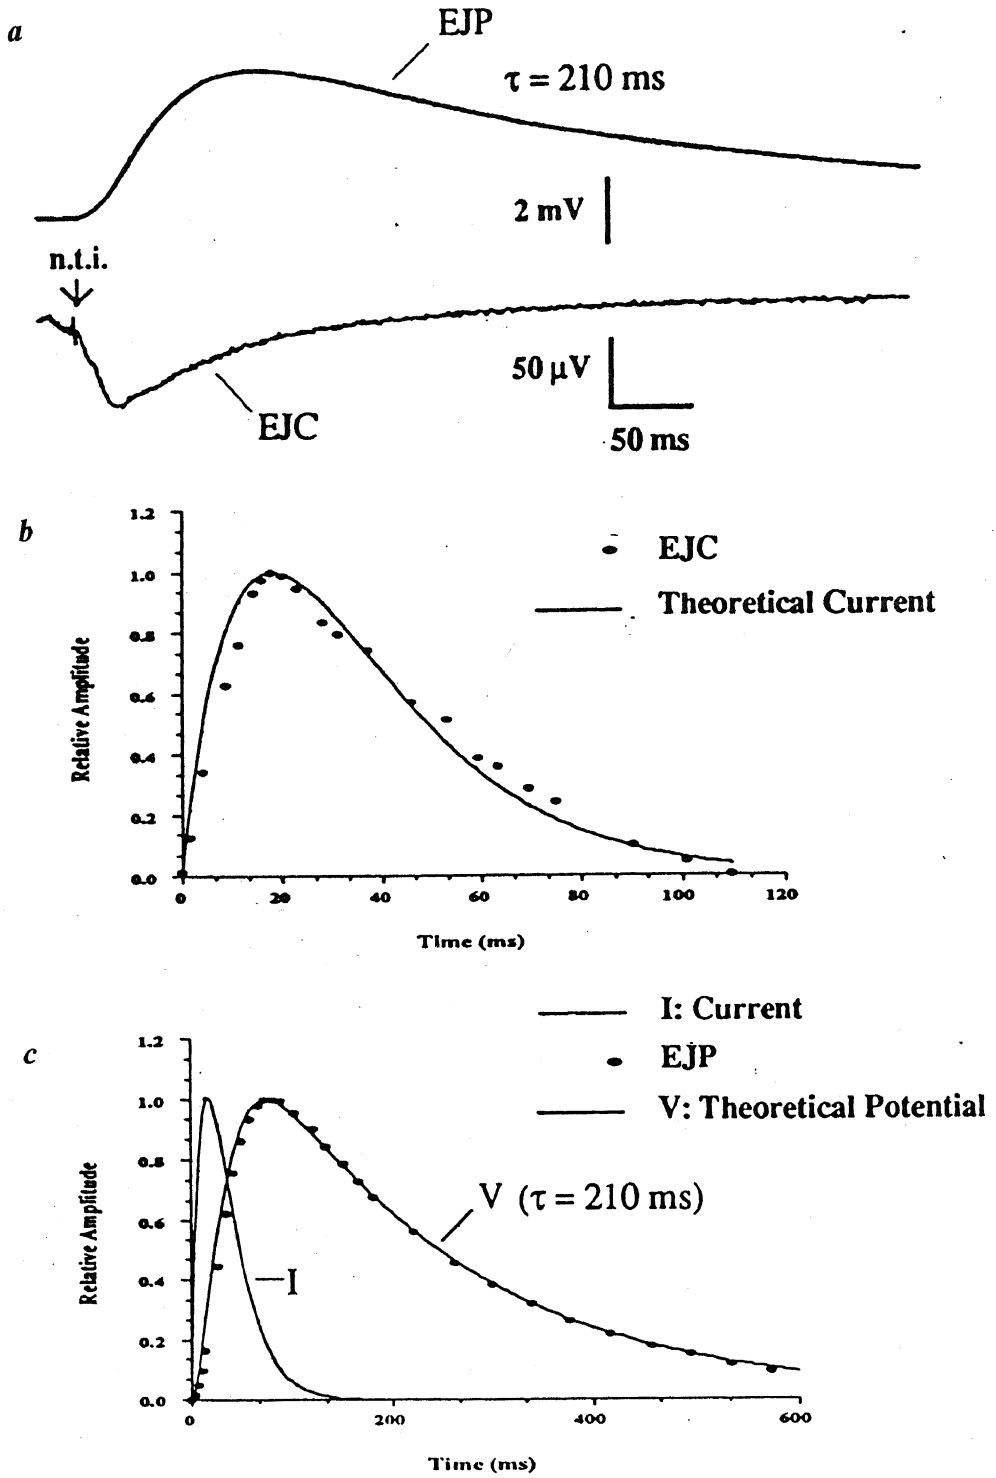

Figure 7. Reconstruction of the EJP from the EJC based on Purves' model[13, 44]: *a*, averages of 80 EJPs and EJCs simultaneously recorded (n.t.i. is the nerve terminal impulse recorded extracellularly); *b*, plot of the EJC in *a* (filled circles) compared to theoretical EJC (smooth curve) generated by equation (4) of the text; *c*, plot of experimental EJP in *a* (filled circles) along with theoretical EJP (smooth curve) generated by Purves' model (equation (5) of text) using the underlying EJC (*I*) as the input. Note the agreement between experimental and theoretical time courses. In *b* and *c*, all events have been normalized with respect to their maximum amplitudes in order to facilitate comparison of time courses.

SEJP is held to be a monoquantal event (on which there is general consensus). Analysis of EJCs and SEJCs using the extracellular recording technique has confirmed this hypothesis of intermittent, monoquantal release from release sites[41–43,46]. However, it should be noted that during an EJP several release sites throughout the

ground plexus are activated, and in this sense the EJP is a multiquantal event. But because the activated release sites are spatially dispersed[46], in the EJP's rising phase only the contribution of one of the closest sites is usually recorded intracellularly as a DE, the contribution of more distant sites being attenuated by electrotronic factors. Since release from each of the sites is monoquantal, and the effect of no more than one of them may be recorded during a given EJP, transmitter release will not appear to be multiquantal. The EJP is graded with stimulation strength because at low strengths fewer intramural axons, and hence varicosities, are activated than at higher strengths, leading to different average levels of depolarization in the tissue. Hence, the EJP can be as small as the smallest SEJP, or as large as the largest, depending upon the stimulation intensity. For a more detailed account of this somewhat unusual quantal relation, the interested reader is referred to the relevant papers and reviews[30,31,41–43,46].

Summary

To summarize, theoretical predictions and experimental results are now in good agreement about the factors governing junction potential time courses in smooth muscle. Extracellular recordings have made it possible to measure the kinetics of junction currents. Simultaneous intracellular and extracellular recordings have established that whereas in the case of the SEJP membrane potential change follows the time course of underlying current, in the case of the EJP it is much more prolonged than the current. Spontaneous and evoked junction currents are similar in time course. These results can be explained in terms of the syncytial nature of smooth muscle by postulating redistribution of charge in a three-dimensional resistive network in the syncytium during the SEJP and in an approximately isopotential resistive–capacitative network during the EJP.

Support to this scheme has been lent by studies on other kinds of smooth muscle, notably vascular smooth muscle, in one particularly interesting case by demonstrating a corollary to the hypothesis. Hirst and Neild[47,48] described a guinea pig submucosal arteriolar preparation which was just one smooth muscle cell layer thick. By using short segments of arteriolar branches which were less than 0.35 length constants long, they showed that the arteriole behaved as a one-dimensional cable even for intracellular current injection. Under these conditions, the time constant of decay of not only the EJP[47] but also the SEJP[48] was shown to be similar in value to τ_m, and the time courses of the EJP and the SEJP were identical. Hirst and Neild[47] also estimated that the membrane currents underlying both the EJP and the SEJP were relatively brief. Hence, when an otherwise three-dimensional syncytium is rendered – by fortuitous physiological arrangement – unidimensional and cable-like, its electrical behaviour becomes similar to that of a skeletal muscle cell. Finkel *et al.*[49] succeeded in voltage clamping this one-dimensional arteriolar preparation with a single-microelectrode voltage clamp system and corroborated these suggestions. It is interesting that the time course of the conductance change in this vascular smooth muscle resembles the time course of the SEJP in the vas deferens[47–50]. In other vascular smooth muscle, where three-dimensional syncytial properties are exhibited, tissue electrical properties resemble those of the vas deferens[51].

Conclusions

In this review I have outlined the often tortuous development of ideas on smooth muscle electrical properties during neurotransmission. It is noteworthy at every stage that the methods adopted for determination of electrical properties have strongly influenced our theoretical picture. Thus, although we now have a hypothesis that consistently explains many observations and may have heuristic value, it might subsequently require modification in the face of new observations obtained with more refined techniques. Additional questions that require attention are:

(i) In some smooth muscles evidence from different lines of experimentation is in conflict regarding whether the cells are electrically coupled. In the vas deferens of the rat and the mouse it has not been possible to demonstrate cable-like properties using the partition stimulation method[36], indicating restricted or absent intercellular current flow, at least in the longitudinal direction. Yet, in these tissues the relationship between the time courses of the junction potentials and the currents is as outlined above[44], indicating effective electrical coupling. Such discrepancies need to be resolved.

(ii) What are the properties, in terms of unitary conductance and mean open time, of the neurotransmitter-activated ion channels which underlie the development of the SEJP and the EJP? Patch clamp studies have so far failed to provide the answer, as only whole-cell recordings have been possible[12]. An alternative approach to the problem might be to carry out fluctuation analysis of transmitter-activated membrane noise[5,37], which would provide indirectly, but reliably, the information of interest.

(iii) Not all EJPs have simple time courses. In many cells their decaying phases can be complex, being described by more than one time constant of decay[52], and one of these phases may be briefer than τ_m. Theoretical studies need to be done on how such EJPs might arise. This may perhaps best be begun by considering simple equivalent circuits for the tissue, intermediate in complexity between the three-dimensional syncytial and the isopotential cases, and estimating the voltage responses in these[53].

(iv) The identity of the subcellular structures that allow intercellular electrical coupling in smooth muscle is controversial. In other syncytial tissues, the structure generally accepted to underlie coupling is the 'gap junction'[54]. However, in the case of smooth muscle the evidence for the existence of gap junctions between cells is equivocal, as is their function when present[54,55]. It will be interesting to see whether a morphological substrate is soon established for the electrical coupling that is so strikingly evident functionally and that plays such an important role in determining tissue electrical properties under different conditions.

Flexicrystallography: Curved surfaces in chemical structures

Alan L. Mackay

Department of Crystallography, Birkbeck College, University of London, Malet Street, London WC1E 7HX, UK

The various periodic minimal surfaces and nodal surfaces, some of which can be related to infinite regular and semiregular polyhedra, extend the vocabulary of crystallography from finite-coordination polyhedra by making visible two-dimensional manifolds in which atoms may be seen to reside. Recently developed computer programs have greatly facilitated advances in this area. Traditional crystallographic geometry does not apply to curved structures but may be generalized to finite and infinite arrangements, where strict equivalence is replaced by quasi-equivalence.

Especially in biology, assemblies of many copies of the same unit, glibly characterized as imperfect crystals, can often be seen to have regularities outside the compass of the 230 space groups.

The term *'flexicrystallography'* is suggested for the geometric regularities observed in what de Gennes calls 'soft matter'. Vesicles, myelin, plant prolamellar bodies and zeolites provide examples of one-, two- and three-dimensional flexicrystals.

In 1934, J. D. Bernal and Dorothy Crowfoot took an X-ray diffraction picture of a crystal of pepsin which showed that it had a definite structure down to atomic resolution. From 1927, W. T. Astbury had been obtaining X-ray diffraction pictures, full of potential information, from silk, wool, cotton and other fibres and the new world of molecular biology (Astbury's words) had been discovered. Bernal and Astbury made a mutual agreement, like the Spaniards and the Portuguese dividing the New World of the Americas between themselves by the Treaty of Tordesillas in 1494, that Bernal should take the globular proteins and Astbury the fibrous for their research.

The methods of X-ray crystal structure analysis since then have proved immensely successful, some 200,000 structures now being known. They require crystals and the price paid for this kind of microscopy is the assumption that all the unit cells in the crystal are identical. Crystallization normally ensures this, but most natural structures are not crystals and their analysis has been left relatively behind, although, for example, TMV (tobacco mosaic virus) particles have now been successfully examined to atomic resolution from ordered textures. Quasicrystals and incommensurate modulation have also required the extension of crystallographic notation and so have fibres and helices, where structural units are basically linear and thus one-dimensional. We now examine structures where atoms or molecules are arranged in curved surfaces and finite and infinite two-dimensional manifolds are prominent.

In 1967, Bernal, influenced by D'Arcy Thompson's 'Growth and Form' and perhaps by Ernst Haeckel's call for a 'crystallography of organic forms', elaborated his earlier ideas for a 'generalized crystallography', which would systematize those structures, often made of only a few types of molecule, which were ordered but not crystalline. The Theoretical Biology Club in Cambridge of the 1930s, which included J. D. Bernal, C. H. Waddington and J. Needham, were convinced that liquid crystal structures were the bridge between living and nonliving matter. The concept of hierarchic levels of organization (integrative levels) was dominant and was much emphasized by Bernal, Needham and by Whyte[1]. However, liquid crystals, vesicles and fibres usually do not fit into the formalism of the 230 space groups. Five-fold symmetry also is outside this framework, although in 1931 Hermann pointed out that textures might have icosahedral symmetry. Combination of this idea with that of hierarchy led to the prediction of quasicrystals, which were discovered in 1984. Pauling's demonstration of the α-helix with 3.6 residues per turn[2], incommensurable with the screw axes of the space groups, showed that crystallography was not enough. Recent developments have advanced towards what we might call non-conformist crystallography or flexicrystallography, where cognizance is taken of structures outside the framework of orthodox crystallography. The key concept is that of the curvature of one-, two- and three-dimensional manifolds. A wide range of curved two-dimensional manifolds is now available as mathematical objects which can be used, as the 230 classical space-groups are used, for conceptualizing the arrangements of atoms and molecules in space. The most important set of these are the periodic minimal surfaces (of which now about 50 are known).

Since the 230 space groups supply the complete answer to the requirement of positioning identical units in three dimensions, the concept of exact equivalence has to be replaced by that of quasiequivalence, as proposed formally by Caspar and Klug in 1962 in connection with the arrangement of more than 60 virus particles on the surface of a sphere. Problems of the quantification of symmetry thus arise since exact identity is ruled out.

Curvature of a surface

At each point (apart from singularities) a surface has two principal curvatures, k_1 and k_2, in perpendicular planes, each including the surface normal. $1/k_1 = r_1$ and $1/k_2 = r_2$, the radii of the tangent circles. The Gaussian curvature K is then k_1k_2 (dimensions L^{-2}) and the mean curvature H is $(k_1 + k_2)/2$ (dimensions L^{-1}). $2H = \text{div } n$, the divergence of the unit vector normal to the surface.

A soap film with equal pressures on its two sides has $H = 0$ (or, if the pressures are different, H is proportional to the pressure difference) and is called a minimal surface. Any small closed loop on such a surface has a minimum area. Given a boundary, a surface across it has $H = 0$, and there may be several, may be stable or unstable (with respect to small displacements).

On a curved surface of radius R the area of a spherical triangle, bounded by arcs of great circles, is given by the spherical excess and is $A = R^2(\pi - A - B - C)$, where A, B and C are the internal angles of the spherical triangle. Thus, there are no similar triangles in spherical and hyperbolic trigonometry, no parallel translations and, consequently, no crystallography.

On a curved surface the perimeter of a small circle of radius r is $2\pi r(1 - Kr^3/3 + O(r^5))$.

The Gauss–Bonnet theorem, which follows from Stokes' theorem, states that the Gaussian curvature integrated over the surface is equal to the integral of the angles between successive segment of the boundary if the latter is made up of geodesics.

Curved surfaces such as those appearing in membranes may be finite or infinite. Finite vesicles, surfaces of lipid molecules surrounding the water phase, may, for example, be spherical or toroidal. Fullerenes[3] may be spherical or tubular or perhaps even infinite. Lyotropic liquid crystal phases may be infinite and periodic. The discovery and classification of periodic curved minimal surfaces has recently advanced rapidly.

Periodic minimal surfaces

Periodic structures have to belong to one or the other of the 230 space groups of classical crystallography and it was the achievement first of H. A. Schwarz and G. R. Neovius, then of A. H. Schoen (1961), then of S. Hyde and S. Andersson and finally of W. Fischer and E. Koch, to find how patches of curved minimal surface can be repeated to give infinite, three-dimensionally periodic, minimal surfaces. In concept, a patch of soap film is hung across the asymmetric region of a particular space group and is repeated by the symmetry operations of that group to give a continuous surface dividing all space into two separate regions (which may be congruent or different). The film where it is repeated by mirror planes and diad axes must join smoothly so that H is zero everywhere. We have here a compromise between locally non-Euclidean sheets and long-range periodicity.

When H is zero, the two curvatures are equal and opposite and their product K, the Gaussian curvature, is everywhere nonpositive. K may be zero at certain flat points or umbilics, for example, where a threefold axis intersects the surface. Since the Gaussian curvature is negative almost everywhere, the two-dimensional surface resembles locally the hyperbolic plane and has a non-Euclidean metric. The perimeter of a circle is greater than $2\pi r$ and thus the hexagonal close packing of spheres, appropriate for the plane, no longer fits tightly. In the plane the mean number of neighbours, the coordination number N, in a triangulated arrangement of points, is 6. On a surface with K negative, N must be greater than 6 and with K positive (as on a sphere), N must be less than 6. Indeed, we know that, as in fullerenes, in order to make a closed shell of hexagons, 12 disclinations where we have rings of five are necessary (or their equivalent in squares and triangles). If we insist on a few rings of seven in a hexagonal net, then a tangle like seaweed may result. A periodic minimal surface is an ordered structure which answers to this requirement for $N > 6$. In anticipation such, as yet hypothetical, structures of carbon have been provisionally named *schwarzites* (by V. Elser after H. A. Schwarz).

Patches, with a locally non-Euclidean metric can thus be sometimes reconciled with three-dimensional crystallinity.

Exact minimal surfaces are quite hard to compute. Exact methods involve the Weierstrass integrals (which are line integrals in the complex plane with elliptic functions). Some of the Weierstrass integrals have recently been solved as algebraic functions which are directly available in modern mathematical computer systems such as Mathematica. Finite element methods are also effective, and have now been brought into a usable form in the Surface Evolver program of K. Brakke, freely available through the Minnesota Geometry Centre for the working chemist who may wish to conjure up a surface to compare it with, for example, an actual zeolite or lipid structure.

The problem of plotting soap-film and other surfaces

Brakke's 'Surface Evolver'

At the Minnesota Geometry Centre, K. Brakke has developed a program Surface Evolver (freely available by electronic mail) which makes the finite element methods of engineering available for problems like those of soap films of arbitrary shape. Many more elaborate calculations involving contact angle, gravity, other functions of curvature, etc., are possible. It works extraordinarily fast on ordinary 486 PC and other computers and greatly extends the possibilities available to individual chemists.

Mathematica

The mathematical program system Mathematica, developed by Steven Wolfram, enables many algebraic, numerical and graphical calculations to be carried out automatically. In particular, we have used the operation ContourPlot3D, which expeditiously draws the surface $f(x, y, z) = 0$, even though the variables may not be separable. Many of the figures here used this. Hypergeometric functions, earlier available only in obscure tabulation, can be called directly for plotting surfaces. The importance of this development on the outlook of chemists towards mathematics cannot be overemphasized. We are in a new period.

has become simplified by the revival of interest in structure factor graphs[4]. These are nodal surfaces in the various crystallographic space groups. When calculations of scattering factor were done by hand, to see if they matched the X-ray diffraction data and thus confirmed the postulated structure (or not), it was useful to see the effect on the calculated structure factors of moving a particular atom and its symmetry-related equivalents. The structure factor in question, a sum of sine waves, could be plotted in space, but, in fact, Bragg and Lipson[5] used only sections. The nodal surface of the structure factor in question divides space into two regions; on one side of the nodal surface the atom contributes positively, on the other side it contributes negatively and on the surface it has zero contribution to the diffracted intensity. The position of an atom can be adjusted accordingly. Now with computer graphics these surfaces can be readily plotted in three dimensions.

It turns out that these nodal surfaces are sometimes close to minimal surfaces with the same space group. Here the symmetry-related sine waves corresponding to a form $\{h, k, l\}$ for a particular space group are added. To get a still better approximation it may be useful to add structure factor expressions for two or more forms. This method of expansion of an arbitrary surface as a series of Fourier terms had been used to describe Fermi surfaces, some of which are similar to the standard periodic minimal surfaces.

The infinite polyhedra (skew polyhedra), found by Coxeter and Petrie when they were undergraduates, are limiting cases where the curved surfaces become flat panels. These have become familiar through their occurrence in zeolite frameworks.

Electrostatic equipotentials

A further important class of surfaces arise in crystallography while considering the Coulomb forces in ionic structures. The zero equipotential between the positive and negative ions in the cubic CsCl (which is primitive cubic with one ion at (0, 0, 0) and the other at $(\frac{1}{2}, \frac{1}{2}, \frac{1}{2})$) is close to the P-surface (the simplest periodic minimal surface). This in turn is close to the nodal surface corresponding to the {1, 0, 0} reflections (three equivalent sine waves). Additional terms can be added to give any required degree of accuracy[6]. Calculation of the potential in a lattice of charges and the evaluation of the Madelung constant are related to the very slow convergence of the lattice sum. However, Ewald's original observation[7] that the potential involved elliptic integrals provides a powerful method which can be used for calculating equipotential surfaces.

Plotting nodal surfaces

Given, for example, the Mathematica program system and an additional program Contour Plot3D, this and other nodal surfaces can be directly generated. However, pictures of the various nodal surfaces can be obtained faster by stochastic method. Either a point can be followed as it runs over the surface following a geodesic, or particle may be reflected back and forth inside one of the two regions of the system and its position can be marked whenever it strikes a surface. This method gives a random dot pattern where the surface is evident only if a stereo pair is constructed. Such pairs could serve as a test for stereopsis after the method developed

Nodal surfaces

Nodal surfaces in a standing wave field are the places where the amplitude is zero. They became familiar in Chladni's demonstration of the movement of fine sand on vibrating plates, although, of course, the Pythagoreans knew of the one-dimensional case of the monochord. Where the amplitude is zero the phase angle is indeterminate.

The physical (as well as the mathematical) formulation of material periodic surfaces by the use of nodal surfaces in acoustic, optical and perhaps X-ray standing-wave fields is also advancing.

The contribution to the reflection h, k, l of one atom with scattering factor f and fractional coordinates x, y, z with respect to a predetermined origin in a crystal with a particular space group crystal is given by

$$F_{hkl} = f(\cos[2\pi(hx + ky + lz)] + i \sin[2\pi(hx + ky + lz)]).$$

The number and phases of the symmetry-equivalent atoms depend on the space group. There may be up to 192 atoms for the most symmetrical cubic case. A low-symmetry space group may generate no surfaces. This was the summation used by Bragg and Lipson.

A variant, relevant for building up arbitrary surfaces, consists in adding all symmetry-equivalent reflections of the form $\{h, k, l\}$ to give an image. (When there are no translation elements the two types of sum may be the same.) The sum may usually be expressed more concisely preferring the products of sine and cosine terms required by the early form of the fast Fourier transform used in the hand summation method of the Beevers–Lipson strips extant before the advent of the electronic computer.

Tables of such structure factor and electron density expressions were developed by K. Lonsdale and W. F. Astbury and are now embedded in the International Tables for Crystallography.

The nodal surface is the plot of the values of (x, y, z) for which $f_{x,y,z}$ is zero. (Both real and imaginary parts of f must be zero.)

A table of nodal surfaces equivalent to various periodic minimal surfaces has been given by von Schnering and Nesper[4].

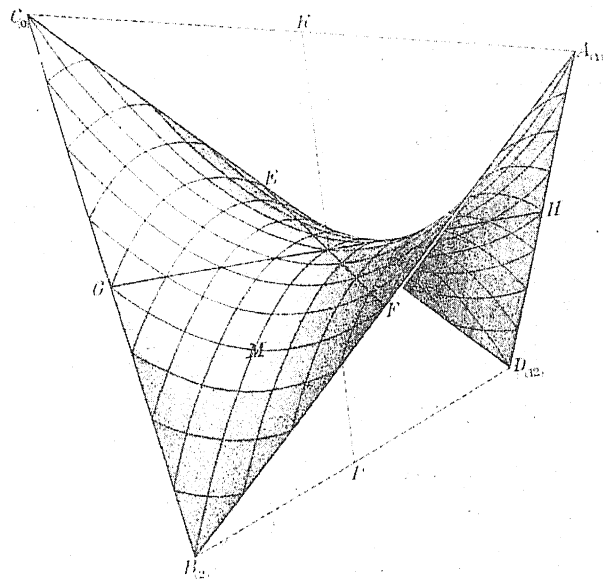
by Bela Julesz. The diffusion of atoms in a molecular sieve can be simulated and parameters such as the Lyapunov coefficient calculated.

Zeolites

Many of the frameworks of zeolite minerals can be seen to lie on periodic minimal surfaces. The clearest example is that of faujasite, where large tetrahedral units – four tubes meeting at 109° to each other, follows the D-surface with a diamond type of structure.

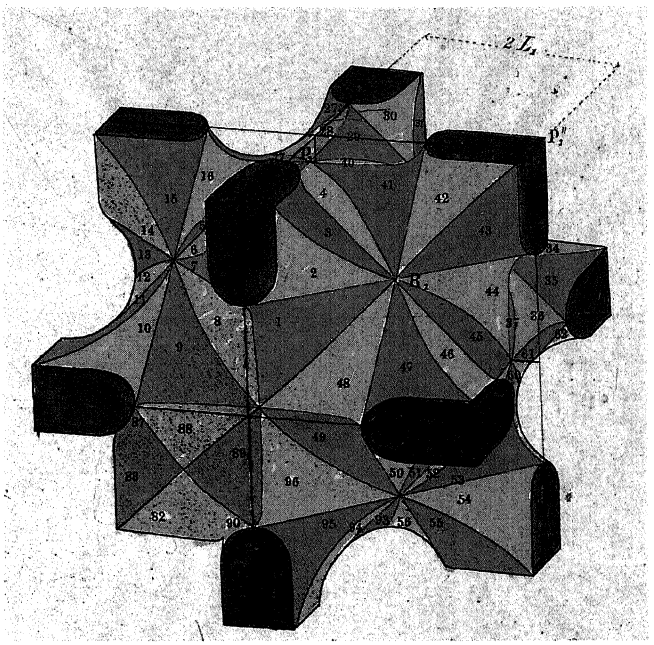
Extension to N-dimensions

Since the expression $\cos x + \cos y + \cos z = C$ gives, as C varies, a set of surfaces parallel to the $\{1\,0\,0\}$ nodal surface, this could be embodied into a generalized form $\cos x + \cos y + \cos z + \cos w = 0$, which would be a four-dimensional nodal boundary. The whole set of parallel surfaces would be obtained as sections through this four-dimensional object. The curved three-dimensional space S^3, which is the three-dimensional analogue of the surface of a sphere, has been used, particularly by Sadoc and Kléman in Orsay, for modelling amorphous materials.



Finite surfaces

Vesicles are small micelles of lipid molecules containing a water phase. Usually, they are spherical, but, recently, toroids[8,9] and elaborate helically twisted cylinders[10], have been observed. They are the most organized and perhaps tractable of the great variety of lyotropic structures encountered in biology.



A closed surface where, for a given volume, the integral of H^2 over the surface is a minimum is called a Willmore surface. For a symmetrical torus this minimum is achieved for a ratio of $\sqrt{2}$ between the two radii. It has also been shown that this integral is invariant with respect to a conformal transformation of the torus into a Dupin cycloid[9].

Curiously, as pointed out also by Andersson[11], the finite crystal forms $\{h, k, l\}$ of traditional mineralogy can be plotted by using expressions similar to the nodal expressions given above for periodic minimal surfaces but replacing sine and cosine by the hyperbolic sine and cosine. Thus, for example with $\{1, 0, 0\}$, $\cosh x + \cosh y + \cosh z = 1000$ gives a cube, and with $\{1, 1, 1\}$, $\cosh(x + y + z) + \sinh(x + y + z) = 1000$ gives a tetrahedron. In the complex plane cosine and cosh are at right angles to each other.

Figure captions

Figure 1. A soap film surface over a tetrahedral frame. Figure from H. A. Schwarz (1865/1890).

Figure 2. The Neovius surface (figure from Neovius' thesis, 1883). One compartment is connected by 12 tubes in the [1 1 0] directions to the next. The space group is $Im\bar{3}m$ if the two sides of the surface are taken to be identical. The 96 equivalent curved unit triangles have angles 45°, 45° and 30° with a deficit of 60° per triangle.

Figure 3. The P-surface (generated as the surface $\cos x + \cos y + \cos z = 0$). This was one of the five found by Schwarz (1865–). The space group is $Pm\bar{3}m$ (thence P for *primitive*) if the two sides of the surface are different, and $Im\bar{3}m$ if they are the same. There are six tubes in the [1 0 0] directions. This surface is also close to that of the $V = 0$ equipotential in the structure of cesium chloride (where Cs^+ is at 0, 0, 0 and Cl^- at $\frac{1}{2}, \frac{1}{2}, \frac{1}{2}$). The 48 equivalent asymmetric triangles have angles 90°, 45°, 30°.

Figure 4. A statistical nodal surface generated by R. Phippen, after J. W. Cahn, by adding 20 sine waves all of the same wavelength but with random phases, directions and amplitudes. The surface is contoured at 0.5, 0.375, 0.25 and 0.125 and may represent an oil/water emulsion.

Figure 5. C_{60}, the molecule of buckminsterfullerene, where 60 atoms are distributed on the surface of sphere, each atom being identically situated. There are two different bond lengths, so that the figure is not exactly that of semiregular Archimedean solid, the truncated icosahedron. Each hexagon has six neighbours and each pentagon five, so that the mean number is less than six.

Figure 6. The D-surface (D for *diamond*) (due to Schwarz). Forty-eight of the tetrahedral saddles shown in Figure 1 are contained in a face-centred cubic cell (space group). If the tetrahedral bonds in the diamond structure are inflated to tubes, so that the volume inside the tubes is equal to that outside, then this D-surface is obtained. Alternatively, the D-surface can be seen as the surface separating the two bonding networks in the structure of cuprous oxide.

Figure 7. The T-surface (T for *tetrahedral*) found by Schwarz. The *c/a* ratio may be varied but the surface is drawn here with $c/a = 1$.

Figure 8. The G-surface (G for *gyroid*) is a remarkable surface found by Alan Schoen around 1960. The space group is $Ia\bar{3}d$ if both sides of the surface are considered equivalent. The two subspaces are mirror images of each other. It is, in a sense, midway between the P- and D-surfaces.

Figure 9. The o-CLP-surface (CLP stands for *crossed layers of parallels in Schoen's nomenclature*, o for *orthorhombic*). One of the 13 new surfaces found by Schoen. It has variable cell dimensions. Drawn with these proportions it shows the way in which catenoidal bridges may connect almost parallel sheets as perhaps in the transformation of a layer-structured lipid to cubically cross-connected structure.

Figure 10. The I-WP-surface (IWP is I (body-centred) *wrapped package* in Schoen's nomenclature) with the space group $Im\bar{3}m$. Here the two subspaces are no longer equivalent but have a volume ratio of $\sqrt{3}$ to 2. Cvijović has given an exact expression for the surface in terms of hypergeometric functions (used here for plotting it). There are eight tubes in the [1 1 1] directions.

Figure 11. The same IWP cell plotted with a different origin.

Figure 12. A $2 \times 2 \times 2$ block of the IWP surface showing how an extended volume builds up. It might be used as a heat exchanger, or for separating two chemicals for a binary reaction, etc.

Figure 13. One of the eight tetrahedral joints which make up the unit cell of the IWP surface. This was plotted by Mathematica with the ContourPlot3D program as the nodal surface of the superposition of several sine waves.

Figure 14. The S-surface, plotted as the nodal surface of the form {2 1 1} with the function $\cos 2x \sin y \cos z + \cos x \cos 2y \sin z + \sin x \cos y \cos 2z = 0$. The space group is $Ia\bar{3}d$ if the two sides are considered identical.

Figure 15. The P-surface in which a graphite net has been embedded with the introduction of disclinations making some rings of six carbon atoms into nonplanar rings of eight. Calculations indicate that this negatively curved structure should be more stable than that of spherical (positively curved) buckminsterfullerene but it remains hypothetical.

Figure 16. A graphite net mapped on to the G-surface (and on to a number of the other surfaces).

Figure 17. The surface of zero mean curvature between two parallel rings is a catenoid, but there are two solutions; one stable (below) and one unstable (above). The stable surfaces are very easily mapped using the finite analysis methods provided by Surface Evolver. Unstable surfaces are more difficult to model and require additional conditions (such as a fixed internal volume).

Figure 18. By changing the positions of the rings in the previous example, the area of the surface of a soap film hanging between two perpendicular circles, each through the centre to the other, can very rapidly be found numerically with the Surface Evolver program. Algebraic treatment is reported to be so far impossible.

Figure 19. Other difficult problems, such as finding the surface of two joined square catenoids, which appear in certain surfaces discovered by Fischer and Koch, are readily solved by the Surface Evolver.

Figure 20. By following geodesic lines on a surface, in this case the dodecahedral nodal surface formed by adding six sine waves, the surface can be mapped out. The trajectory of a point is deterministically chaotic and eventually covers the whole surface.

Illustrations

The plates illustrate a number of shapes now being produced. They are explained in the associated captions.

Observed and theoretical acceleration response spectra in the Tehri region: Implications for seismic hazard in the region

K. N. Khattri

Wadia Institute of Himalayan Geology, 33, General Mahadeo Singh Road, Dehra Dun 248 001, India

This paper presents an estimate of the seismic hazard in the Tehri region of the Himalaya. Theoretical simulations of strong motion expected in the vicinity of the fault of a $M_s = 7$ earthquake are used in conjunction with observed strong motion data for the 1991 Uttarkashi earthquake to conclude that for such an earthquake the peak acceleration at Tehri can be ~ 0.8 *g*. The corresponding spectral acceleration at $T = 1$ s can be ~ 0.98 *g*. Analysis of the strain budget of the region and a finite probability of occurrence of a great earthquake ($M_s > 8$) in the next 100 years or so is estimated. The spectral acceleration (T~ 1–2 s) in the near-field region of such an earthquake is estimated to be of the order of 1 *g*.

ESTIMATION of seismic hazard is ordinarily based on one-parameter characterization of ground shaking, such as peak ground acceleration, peak ground velocity or peak ground displacement. The maps specify values of the chosen parameter at various sites with a given probability of exceedance in a chosen time span. Such single-parameter descriptions are most appropriate for characterizing the damage potential to short-period structures. However, in assessing the damage potential to complex structures such as dams and power plants, where a range of periods of the main structure and the substructures are involved, the details of the strong ground motion histories are needed to estimate properly the seismic hazard. For the purposes of seismic hazard characterization, the information in strong-motion time history is transformed into response spectrum, which specifies the levels of expected spectral accelerations at various periods.

Modelling is a standard scientific technique used for identifying the essential features of natural phenomena. Models are used to extrapolate and predict phenomena in domains for which empirical observations may not be available, but are needed. This is especially true in strong-motion seismology, as relatively few strong-motion accelerograms have been recorded so far, and the expected strong-motion time histories in earthquake-prone zones are needed to determine the parameters for earthquake-resistant design of structures.

In this paper we use the composite source model to represent a hypothetical earthquake similar to the 1991 Uttarkashi earthquake (M_s =7) placed near Tehri, and use wave propagation theory to simulate the strong ground motions at Tehri[1–3]. We compare the results with those recorded for the Uttarkashi earthquake and show that the simulated strong ground motions are realistic.

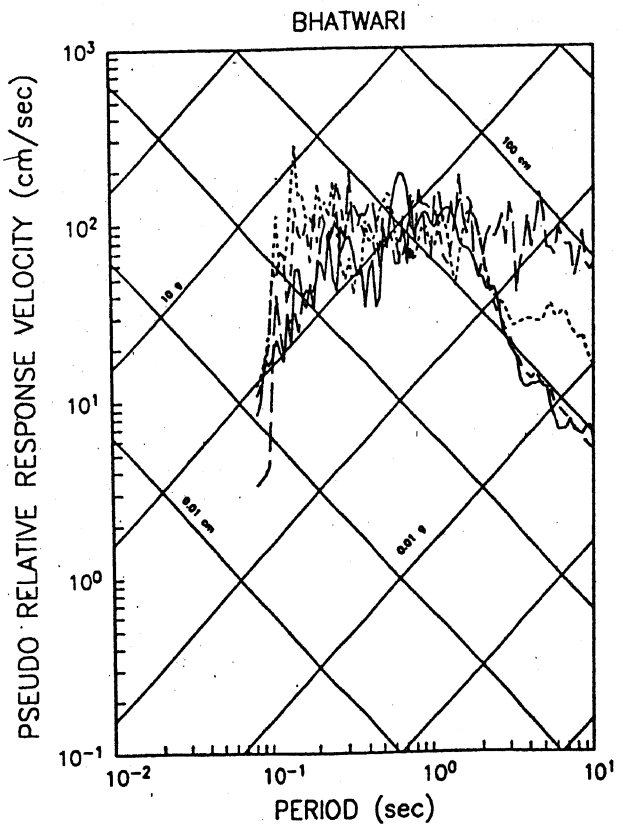

Figure 1. The observed pseudorelative response spectra at Bhatwari for the 1991 Uttarkashi earthquake ($M_s = 7$) are shown by solid line. The synthetic spectra for Uttarkashi earthquake are shown by short dashes (no filtering of the synthetic accelerogram) and by intermediate dashes (filtering of the synthetic accelerograms with a filter equivalent to the one used in the observed accelerogram data processing. The long dashes show the response spectrum for an $M_w = 8.5$ earthquake[2]. Note that the agreement between the observed and the synthetic response spectra is good for periods longer than 0.2 s. The damping in all cases is at 5%.

We compute the response spectra for the simulated event, and compare them with the response spectra obtained at Bhatwari and Uttarkashi for the 1991 Uttarkashi earthquake. These sites were at comparable distances from the surface projection of the respective fault plane edge as was the simulated event from the surface projection of the fault plane edge of the hypothetical earthquake.

The magnitude of the most damaging earthquake that may strike the region in the next 100 years or so is also estimated using the available data on the past history of great earthquakes, the geological model of active tectonics in the region, and the strain rates obtained from a variety of geological and geophysical measurements as well as seismological data. The corresponding peak as well as spectral accelerations expected in the earthquake fault region are estimated. The peak accelerations expected on the basis of probabilistic analysis of seismological data are estimated and compared with those determined by the deterministic methods mentioned above.

The modelling procedure

The ground motions due to an earthquake depend on the position and nature of the earthquake source and the properties of the intervening medium; density, wave velocity and wave attenuation as a function of space coordinates. Knowing these parameters one can use the available theoretical frameworks to estimate the expected strong ground motions at a site.

Since earthquakes involve a complex process of rock fracturing, the procedure consists of representing the earthquake fault as a superposition of a large number of smaller circular subfaults distributed randomly over the earthquake fault plane. This models the heterogeneous nature of the earthquake faulting process. The number of subfaults with a given radius (R) is proportional to $(1/R^D)$, where D is a fractal dimension. All subevents are assumed to have the same stress drop. Each subfault radiates a Brune source pulse[4, 5]. The sum total of moments of all the subfaults is constrained to equal the earthquake moment. The rupture is initiated at the hypocentre and sets off other subfaults as its rupture front expands and touches their centres. The elastodynamic radiation, for an appropriate model of earthquake source, is propagated to the site of observation by using numerically synthesized Green's functions for an appropriate layered earth structure. For $D = 2$, one obtains an ω^{-2} falling off of the spectrum at high frequencies of the elastodynamic radiation from a composite fault as used here. This is consistent with the empirical observations[6].

Results

Khattri *et al.*[2] and Yu *et al.*[3] used the above approach to model the strong ground motion records of the 1991 Uttarkashi earthquake and showed that the technique is able to reproduce the essential stochastic features of the observed data. The corresponding response spectra were also well matched over a wide range of periods. An example of this is shown in Figure 1. The response effects of the local (shallow) site geology, which is not known, is the most likely cause for the observed differences between the observed and the simulated spectral accelerations. Other factors that can contribute to the differences are inaccuracies in the velocity models used, as well as resonance effects of the severe topography in the region.

In this paper we use the above technique to estimate the nature of strong ground motions at Tehri expected for a hypothetical future earthquake of magnitude

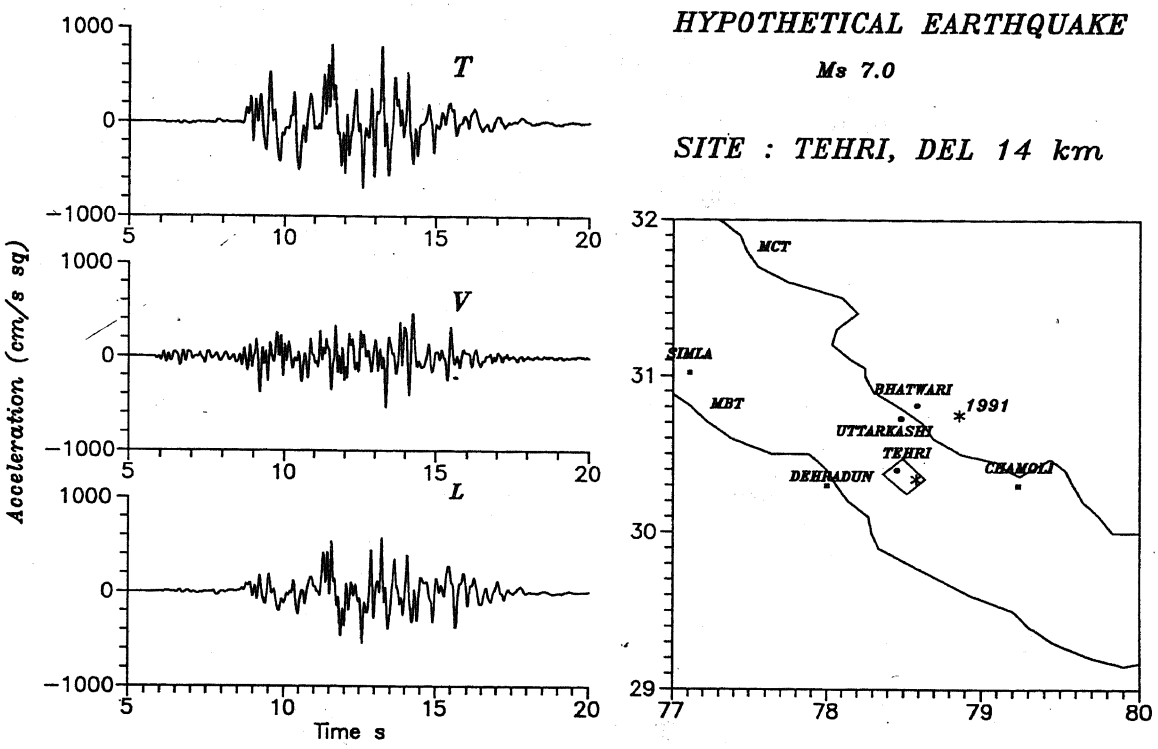

Figure 2. Accelerograms synthesized at Tehri for $M_s = 7$ earthquake. The location of the earthquake is shown as inset in Figure 3.

$M_s = 7$, having similar fault plane solution and focal depth as the 1991 Uttarkashi earthquake. The fault plane of the hypothetical earthquake lies in the vicinity of Tehri, as shown in Figure 2. Tehri is located near the NW corner, but lies within the surface projection of the fault plane. The fault plane is located at a depth of 12 km with a dip of 14° towards NW. The strike of the fault plane is 317°. The area of the model fault plane is 16×24 km^2. This is based on the evidence for the 1991 Uttarkashi earthquake and the empirical relation available between fault dimension and the earthquake magnitude[7]. The slip is of thrust type, with the overthrusted block moving in an approximately SW direction. The velocity model used is shown in Table 1[2, 3]. Note that a top layer of low velocity is included in the model to represent a weathered layer, and (or) sediments. A stress drop of 30 bar is used in the simulation.

The synthetic acceleration time histories at Tehri for the transverse, vertical and longitudinal components are shown in Figure 2. The duration of strong shaking is approximately 8 s. The transverse component shows the largest value of 816 cm/s^2 for the peak acceleration. The peak acceleration values for the longitudinal and the vertical components, respectively, are 573 cm/s^2 and 537 cm/s^2. There is a lower-frequency component in these accelerograms which seems to separate the larger acceleration peaks.

Figure 3 shows the spectra of the acceleration time histories. The spectra show a corner at a frequency of about 0.02–0.04 Hz, which corresponds to a source dimension radius of ~8 km. This is consistent with the subfault size chosen for modelling the earthquake ground motions. At 10 Hz the sudden drop in amplitude is due to the computation of the Green's functions up to that frequency only.

The acceleration response spectra at 5% damping are shown in Figure 4. The highest spectral accelerations of about 2 g are observed in the short period range of 0.1–0.7 s. At a period of 1 s, the spectral acceleration value is ~ 1 g for the T component, ~ 0.7 g for the L component and ~ 0.3 g for the vertical component. At a period of 2 s, the spectral acceleration value is ~ 0.8 g for the L component, 0.55 g for the T component and ~ 0.2 g for the vertical component.

Discussion

Accelerations near the fault zone

We discuss the theoretical results obtained above in the light of the observed strong motions at Uttarkashi and Bhatwari for the 1991 $M_S = 7$ Uttarkashi earthquake. These sites are located close to (within about 2–10 km) the surface projection of the inferred fault plane. Also, they are located in the direction of rupture propagation. In the simulated model, the Tehri site is located over the surface projection of the fault plane, about 7 km inside it. It is also in the direction of rupture propagation.

The observed accelerograms for Bhatwari and Uttarkashi are shown in Figures 5 and 6, respectively. Bhatwari is at an epicentral distance of 25 km and Uttarkashi at 36 km. Although the epicentral distance loses its conventional meaning in the near field of the earthquake, it serves to provide a reference scale in terms of relative positions with respect to the fault plane as well as the fault dimension. The propagation effects will also be governed by this parameter. Peak accelerations of 0.24 g, 0.30 g and 0.19 g have been recorded for L, T and V components, respectively, at Uttarkashi. Similarly, peak accelerations of 0.25 g, 0.24 g, 0.29 g have been recorded for L, T and V components, respectively, at Bhatwari.

The peak acceleration represents the high-frequency component of the energy, and most of it will be contributed by the faulting process near the site. Since both Bhatwari and Uttarkashi are at similar distances from the fault edge, they are likely to have similar values of the peak accelerations. Such is indeed the case, as is documented above. However, at lower frequencies (longer periods) the contributions from the entire fault plane will be important, as they will become increasingly coherent with longer periods (wavelengths). Thus, the entire fault plane will contribute to the energy. The epicentral distance will also play a more significant role in determining the amplitude. This phenomenon can be observed better in the response spectrum.

The response spectra at Bhatwari and Uttarkashi are shown in Figures 7 and 8, respectively. We note that the shorter-period spectral responses (0.1–0.4 s) show comparable levels at the two stations, in keeping with simi-

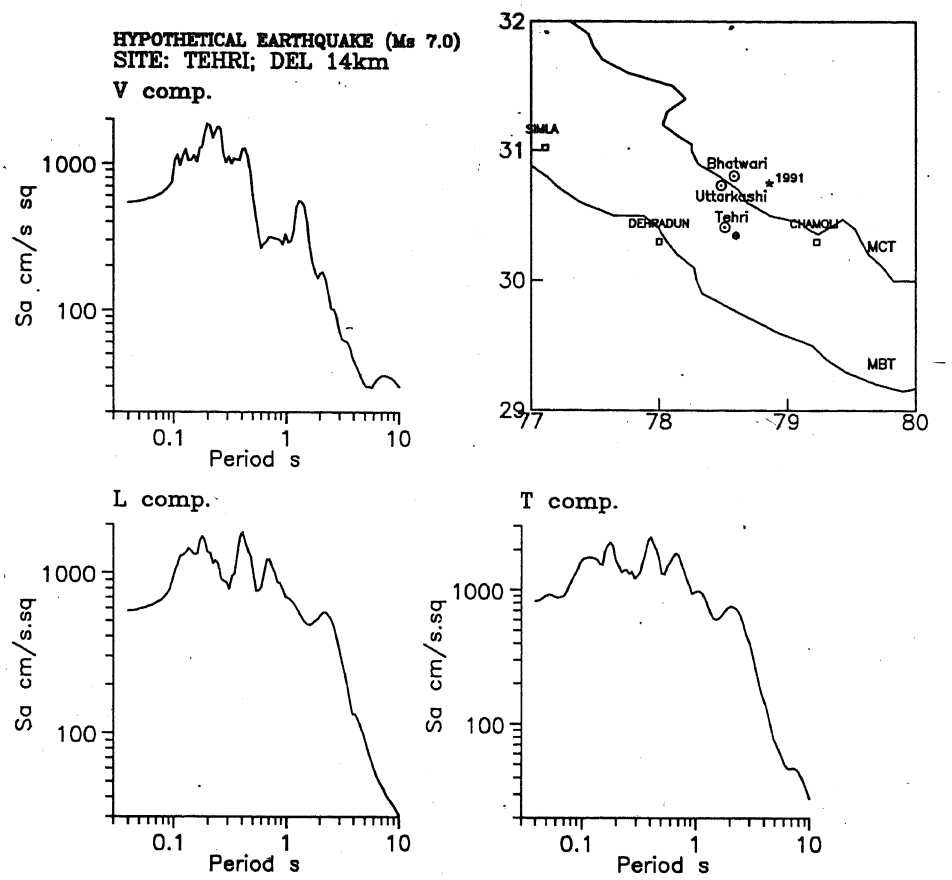

Figure 4. Response spectra at Tehri for 5% damping.

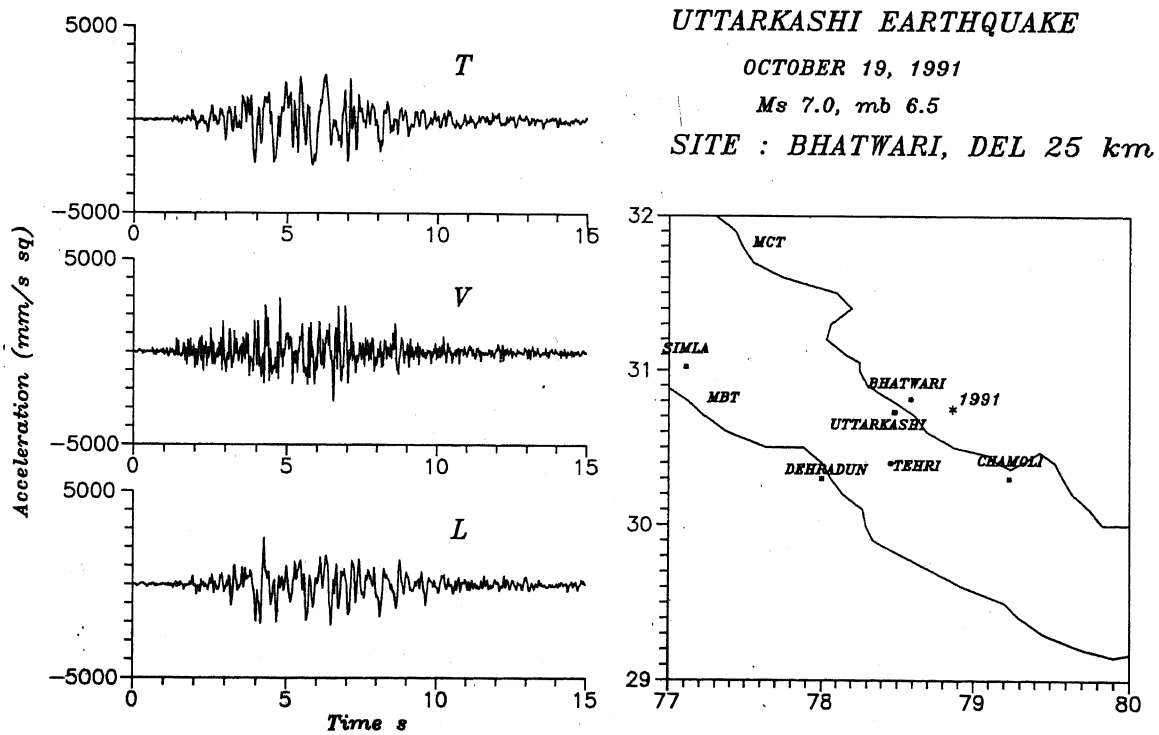

Figure 5. Accelerograms recorded at Bhatwari for the 1991 Uttarkashi earthquake ($M_s = 7$).

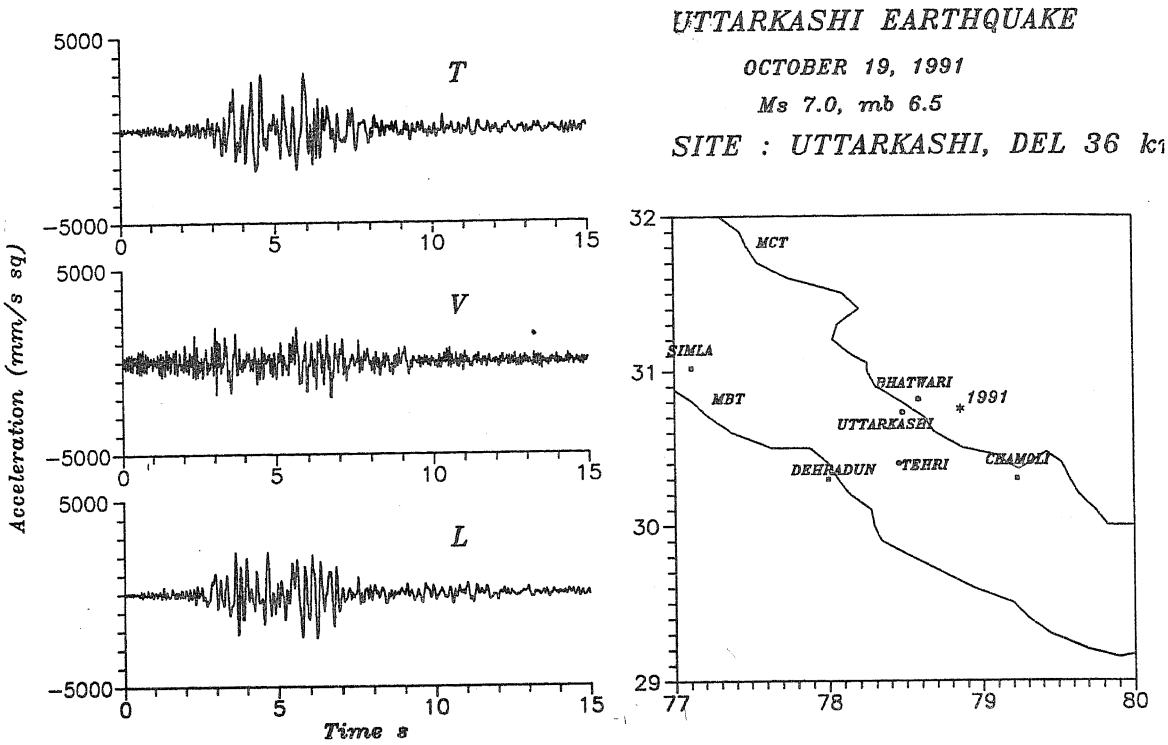

Figure 6. Accelerograms recorded at Uttarkashi for the 1991 Uttarkashi earthquake (M_s = 7).

lar observations for the peak acceleration values. However, the long-period spectral responses begin to show the effects of epicentral distance. For example, at ~ 1 s period, the spectral accelerations at Bhatwari and Uttarkashi are, respectively, 0.22 *g* and 0.10 *g* for the L component, 0.43 *g* and 0.18 *g* for the T component, and 0.11 *g* and 0.10 *g* for the V component. Similarly, at 2 s period, these values are 0.08 *g*, 0.03 *g* for the L component, 0.11 *g* and 0.04 *g* for the T component, and 0.06 *g* and 0.05 *g* for the V component. We notice a falling off of spectral acceleration amplitudes for the horizontal components by a factor of about 3 at these longer periods for a change of epicentral distance from 25 km for Bhatwari to 36 km for Uttarkashi, i.e. an increase of 11 km.

Let us now consider the results obtained for the case of simulation for Tehri. As noted above, peak accelerations of 0.82 *g*, 0.57 *g* and 0.53 *g* have been obtained for T, L and V components, respectively. The largest value is higher by a factor of about two-and-a-half compared to the observed value at Uttarkashi. This increase is theoretically anticipated on account of the smaller distance of Tehri to the fault plane, its smaller epicentral distance (~ 14 km), as well as resonance effects of the near-surface low-velocity layer at Tehri.

The estimated spectral accelerations at Tehri are about 3 to 4 times those observed at Bhatwari for periods up to ~ 1.7 s. At 2 s period, an amplification by 7 has also been observed. In general, the scaling is increasing for longer periods both for the empirical data set (from Uttarkashi to Bhatwari) as well as in the synthetic case (from Bhatwari to Tehri). As discussed above, this is a consequence of increasing coherency of the elastodynamic radiations at longer periods. The scaling by a factor of 3 to 4 is consistent with similar scaling observed between Bhatwari and Uttarkashi for a reduction of 11 km in the epicentral distance. The epicentral distance reduction for Tehri is 10 km with respect to the epicentral distance for Bhatwari. The various data described and discussed above are given in Table 2. The systematic dependence of the spectral accelerations on the epicentral distance discussed above is shown in Figure 8.

The synthetic strong-motion histories are consistent with the observed data at Bhatwari and Uttarkashi for the 1991 Uttarkashi earthquake. They have the appropriate amplitude envelope, duration and frequency characteristics. However, as discussed above, the observations at Bhatwari and Uttarkashi do not provide a suitable basis of estimate of the peak acceleration at Tehri, as both these sites were outside the fault zone; secondly, the Tehri site is well within the fault zone in the model calculations; and thirdly, it includes a low-velocity layer at a shallow depth, which will introduce

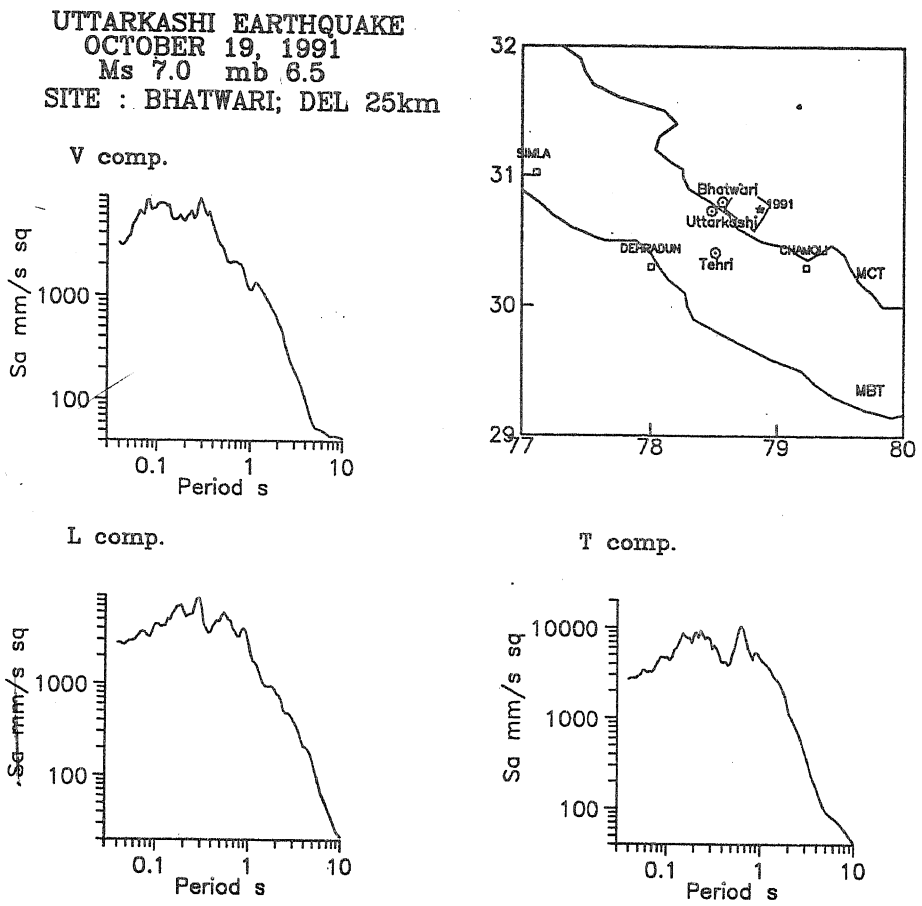

Figure 7. Response spectra at Bhatwari for 5% damping, for the accelerograms in Figure 4.

resonance effects at shorter frequencies. Such a layer is not expected to exist at either Bhatwari or Uttarkashi, both of which are located adjacent to the High Himalaya having a very high rate of erosion. But such a layer is expected to be present at Tehri as indeed brought out from the analysis of the strong motion data for the Uttarkashi earthquake[3]. Furthermore, peak ground accelerations of about 1 g near the faults have been recorded in several earthquakes[8, 9]. Therefore, the maximum peak acceleration of 0.82 g obtained for the T component is a realistic estimate.

The observed data as well as the foregoing analysis indicate that the synthetic accelerograms and the corresponding response spectra for the Tehri site represent a realistic seismic hazard scenario for the type of earthquake and the site under consideration.

Estimation of the most damaging future earthquake in the Tehri area within the next about 100 years

Estimation of seismic hazard in a region depends on the most damaging earthquake that can occur in the region in the time window under consideration. This is illustrated by considering the accelerations expected for large earthquakes. For example, the Idriss[10] formula provides the following estimates for acceleration values for the cases of $M = 8$ and $M = 8.5$ earthquakes at distances of 15 and 25 km (see Table 3).

Table 3 shows two things. First, *there is a drastic increase in the expected acceleration amplitudes as we go from $M = 8$ to $M = 8.5$. Secondly, the high values of the spectral accelerations imply a long duration of shaking with high acceleration values.*

An estimate of the peak acceleration acquires significance when, as is often the case, the seismic response spectrum based on site-specific observational data is not available. In such situations, the amplitudes of the response spectrum are scaled by anchoring the spectral acceleration at zero period of a standard mean level spectra, at the level of the peak acceleration expected for the site, or a parameter based on the same. However, alternative new techniques based on sound theoretical models, such as the one presented here, have now become available to provide estimates of the expected strong ground motion time histories and the corresponding response spectra.

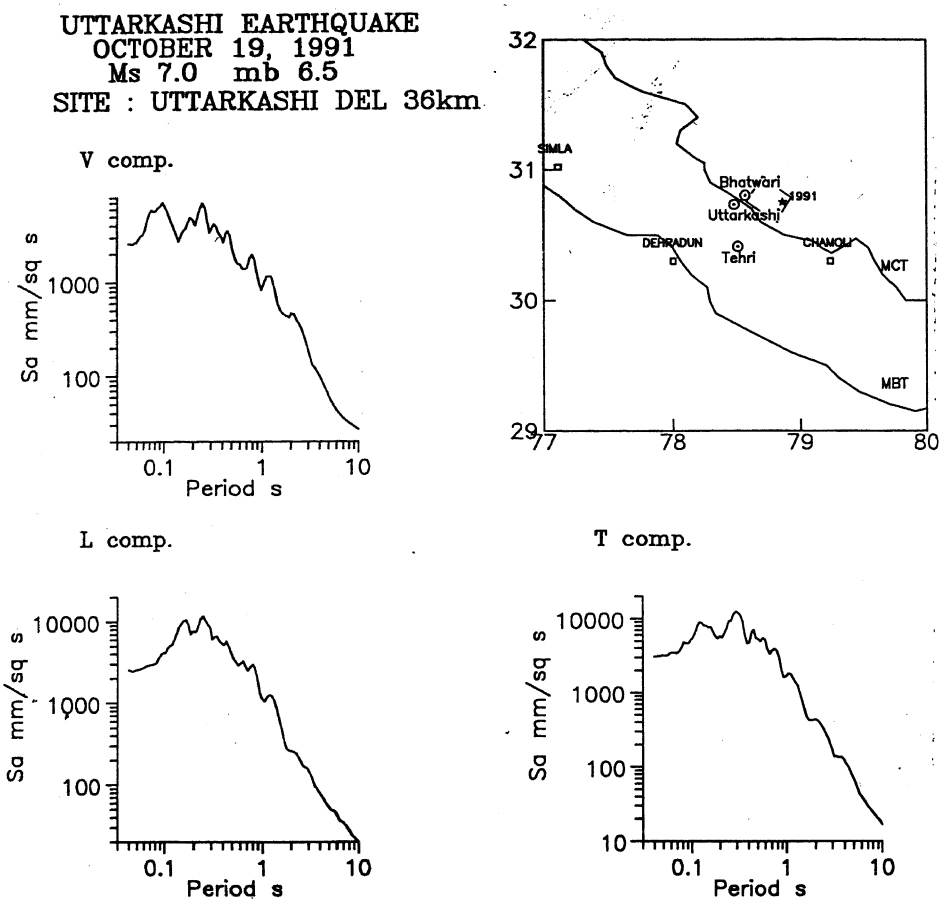

Figure 8. Response spectra at Uttarkashi for 5% damping, for the accelerograms in Figure 5.

The Himalayan belt is one of the most actively deformed zones on earth[12, 13], formed as it is by a succession of processes of strain accumulation and its catastrophic release in the form of earthquakes. The region has experienced four great earthquakes in the past about 100 years, namely, the 1897 Assam earthquake ($M = 8.7+$), the 1905 Kangra earthquake ($M = 8.6$), the 1934 Bihar–Nepal earthquake ($M = 8.4$), and the 1950 Assam earthquake ($M = 8.7$). The occurrence of peak accelerations in excess of $1\,g$ in the great 1897 Assam earthquake has been well documented[14]. Since the geological process of the collision of the Indian plate with the Eurasian plate continues, causing persistent accumulation of strain, it makes certain that such great earthquakes in the Himalaya will continue to occur in the future.

An appraisal of the average return period of the $M = 8+$ earthquake in the region is, therefore, pertinent to the problem of seismic hazard estimation. This can be based on the strain budget of the region. The frequency of great earthquakes is constrained by the rate of strain accumulation in the region. The rate of strain accumulation has been estimated using a variety of techniques. The average rate of plate convergence obtained from marine magnetic anomalies is 5 cm/annum[15]. However, a fraction of this is transferred to the region north of the Himalaya. Thus, it sets an upper limit on the rate of strain accumulation in the region. Using the deformation of the upper Tertiary sediments in the Ganga foredeep, the average rate of strain is estimated to be 1.0–3 cm/annum in the western parts of the Himalaya[16, 17]. In the U.P. part of the Ganga foredeep, the average rate of convergence estimated from the velocity of the southward onlapping of the Indian shield is 1.8 ± 0.4 cm/annum[18]. The elastically stored component of the average rate of convergence estimated by using the rate of seismic moment released by great earthquakes in the Himalaya is 1.7 ± 0.3 cm/annum[19]. This strain becomes available for causing future earthquakes in the region. Using the fractal description of earthquake occurrences together with the complete catalogue of earthquakes, the average rate of slip over the basement thrust in the Himalaya has been estimated to be 3.5 cm/annum[20]. This rate will be approximately equal to the average rate of

convergence in the Himalaya. Geodetic measurements using levelling in Dehradun and Kathmandu areas have been analysed to provide an estimate of the average rate of elastic strain accumulation to be 0.7 cm/annum in the outer Himalayan region[21]. The GPS measurements in Nepal have led to an estimate of the convergence rate of 1 ± 1 cm/annum[22].

From the foregoing discussion it is clear that the average rate of convergence in the Himalaya lies in the range of 1–3 cm/annum. The rate may vary along different

Table 3. Acceleration values using Idriss formula[10], quoted from Liam-Finn[11]

	$M = 8$		$M = 8.5$

sections of the Himalaya. This can be revealed by detailed investigations using modern techniques like the GPS.

If one considers the average rate of elastically stored convergence to be 2 cm/annum then sufficient strain will become available in any sector of the Himalaya to generate a great earthquake in a period of about 500 years. In the sector in front of the Salt range, where the rate has been estimated to be 1 cm/annum, the average return period will be correspondingly longer. In the sector containing the Pir Panjal Range, where the rate of convergence is estimated to be 3 cm/annum, the average return period is anticipated to be shorter. In the central gap region the estimated rate of convergence is close to the average value. Therefore, the 500-year return period is quite representative.

The four great earthquakes in the Himalaya over the past 100 years have between them relieved the accumulated strain in about 35% of the Himalayan plate boundary. The remaining sections of the Himalayan plate boundary have not experienced a great earthquake for the past at least 300 years, possibly 500 years or more. Thus, these sections, constitute veritable seismic gaps, with a large amount of accumulated strain, and are, therefore, places of high seismic potential for a future great earthquake in the next 100–300 years or so. The Tehri dam site lies in one such gap (Central gap)[23, 24], for which the shorter time interval applies.

It is also relevant to consider peak accelerations in the Himalaya, estimated using the standard probabilistic seismic hazard analysis[25]. The peak accelerations expected in the Lesser Himalaya (where the dam is sited) are $0.7^{+}g$ for a one in ten chance of exceedance in any time window of 50 years. When this is translated to a 100-year exposure period, the a_p value scales to about $0.9\,g$ (ref. 26).

The analysis of both the seismological and the strong-motion data are consistent in estimating that for the case of a great earthquake both the peak and the spectral accelerations ($T \sim 1$ s) in the fault zone in the Tehri region are expected to be around $0.9\,g$.

Conclusions

Recapitulating, the following conclusions emerge from the present investigation.

1. The observational strong-motion data for the 1991 Uttarkashi earthquake ($M_s = 7$) show that spectral accelerations of $0.43\,g$ ($T = 1.04$ s), $0.36\,g$ ($T = 1.23$ s) and $0.26\,g$ ($T = 1.5$ s) have been recorded at an epicentral distance of 25 km.

2. The corresponding synthetic strong motions for a hypothetical $M_s = 7$ earthquake at an epicentral distance of 14 km and located within the surface projection of the fault zone are $0.98\,g$ ($T = 1.04$ s), $0.85\,g$ ($T = 1.23$ s) and $0.60\,g$ ($T = 1.5$ s).

3. The spectral accelerations in the 1–2 s period range, estimated from model simulation at Tehri for the case of an $M_w = 8.5$ earthquake situated under Tehri at a depth of 12 km, are $\sim 1\,g$ (refs. 7, 8).

4. The Idriss[10] as well as the Campbell[27] empirical formulae also give spectral accelerations ($T = 2$ s) at 15 km distance to be at least $\sim 0.57\,g$ for an $M = 8.5$ earthquake. The acceleration will be higher at a closer distance of 12 km.

5. The rate of strain accumulation in the Central Gap (where Garhwal is situated) is around 2 cm/annum, which provides enough strain accumulation to generate a great earthquake in about 500 years. Since there has been no great earthquake in this gap for at least about 300 years and perhaps 500 years, the region (Central Gap) must be ripe for a great earthquake in the next 100 years or so. Of course, it is possible that the accumulated strain is initially released partially in a number of $M = 7$ or so earthquakes, instead of a single great earthquake ($M > 8$). In this case the occurrence of the great gap-filling earthquake will at best be somewhat delayed, but not forestalled. However, the scenario historically repeated by all great earthquakes in the Himalaya is the most appropriate basis for estimating seismic hazard.

6. The probabilistic seismic hazard analysis of the Himalaya shows that in any 100-year time window the probability of exceeding a peak acceleration of $\sim 0.9\,g$ in the Garhwal Himalaya is 0.1.

7. The above estimates of the seismic hazard characterization are consistent with the currently available corpus of geological, geophysical, seismological and earthquake strong-motion data. Therefore, it would be prudent to heed these estimates while scientifically evaluating the soundness of the aseismic design of large critical structures in the region.

8. There is a very high level of seismic hazard in the seismic gaps and in adjacent areas to their south with their densely populated centres. A systematic implementation of a well laid-out hazard mitigation plan is urgently called for.

Sr isotopes in rivers of India and Pakistan: A reconnaissance study

J. R. Trivedi, Kanchan Pande, S. Krishnaswami and M. M. Sarin

Physical Research Laboratory, Ahmedabad 380 009, India

It is well established[1] that the isotopic composition of Sr in sea water has oscillated on different time scales during the past ~600 Ma. These oscillations result from changes in the relative contributions of dissolved Sr to sea water from its two major sources, continental weathering and hydrothermal interactions, with their characteristic $^{87}Sr/^{86}Sr$. The continental input via fluvial weathering is generally more radiogenic (average $^{87}Sr/^{86}Sr$ 0.7119 ref. 2) compared to the hydrothermal $^{87}Sr/^{86}Sr$ of 0.7035 (ref. 2). The Sr flux and $^{87}Sr/^{86}Sr$ of different river systems vary widely[2–4] and in some way are related to the lithology of the drainage basin, the intensity of weathering and the efficiency with which they transport their dissolved load. We have measured the dissolved Sr concentrations and $^{87}Sr/^{86}Sr$ of the major rivers draining India and Pakistan. These measurements provide data on the flux of Sr isotopes transported by these rivers to the ocean and their impact on the Sr isotope evolution of the oceans. Further, as the river basins sampled comprise a diverse set of lithologic, tectonic and climatic regimes, they provide an opportunity to study the controls of these factors place in determining the Sr isotopic systematics of rivers.

THIS work forms a part of our geochemical reconnaissance study of the Indian rivers. Major ions, Sr and U isotopes were the principal constituents measured in the samples, the results of some of our earlier work are published elsewhere[5–9]. Figure 1 shows the sampling sites.

The rivers sampled can be conveniently classified into two groups[10,11] in terms of their basin geology, tectonics and climate – the peninsular and the extrapeninsular (Himalayan). The peninsular region is a tectonically quiescent shield area that has several mountain systems such as the Aravallis, the western and eastern Ghats and the Nilgiris, most of which are geologically mature. This shield is made of Pre-Cambrian rocks of diverse origin,

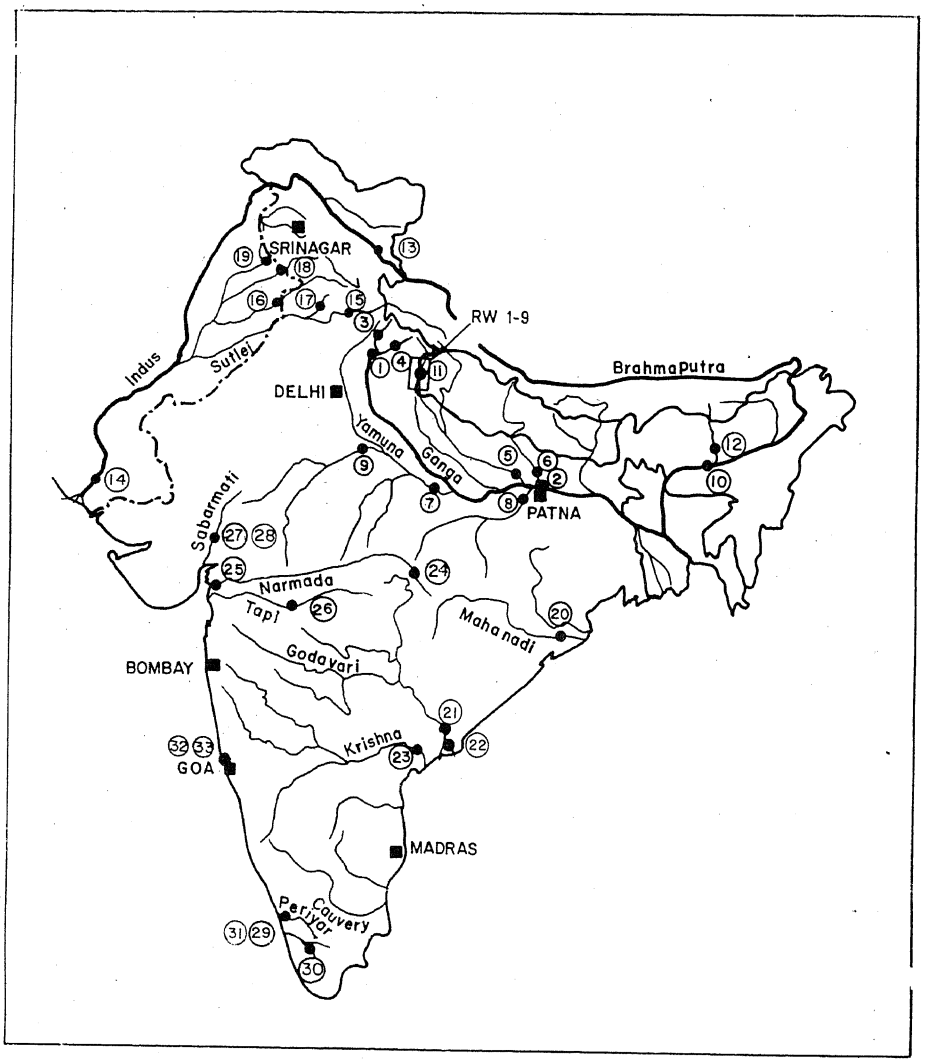

Figure 1. Sampling locations of rivers from India. The sampling location of Indus and its tributaries are given in ref. 9. The locations of samples from the Kali–Sarju system (RW 1–9) are marked by rectangle.

most of which have been greatly modified and metamorphosed. These ancient rocks (gneisses, granite, charnokites, greenstones, granulites, etc.) are overlain in many areas by Pre-Cambrian and later sedimentaries (Cuddapah, Vindhyan, Delhis and Gondwanas) and by extensive sheets of lavas of the Cretaceous/Tertiary Deccan traps. Some Mesozoic and Tertiary sediments are also found along the coastal regions[10,11].

There are a number of rivers traversing the peninsular India, the larger ones being Mahanadi, Godavari, Krishna, Pennar and Cauvery, which flow eastward into the Bay of Bengal, and Narmada, Tapi, Sabarmati and Periyar, flowing westward into the Arabian sea. Banas, Luni, Chambal, Sindh, Betwa and Son are the peninsular rivers (lowland rivers[5]) belonging to the Ganga system.

Similar to the peninsular region, the extrapeninsular (Himalayan) region also contains some Pre-Cambrian rocks. These old rocks in the Lesser and Greater Himalayas are comprised predominantly of granitic gneisses and crystallines[12,13]. In the Lesser Himalaya there are also extensive exposures of sedimentary sequences (carbonates, sandstones, shales). The peninsular and extrapeninsular regions are separated by the Indo-Gangetic alluvial plain consisting of massive beds of clay, sand and gravel. The clay zones of alluvial plains contain impure calcareous material in the form of irregular concretions called 'Kankar'. The calcareous material at places can be as abundant as 30%. A large part of the soils is impregnated by alkaline and saline salts[5]. In contrast to the peninsular shield area, the Himalayas are

tectonically active, still rising and being extensively eroded by the fast-flowing rivers. Glaciers abound the higher reaches and also contribute to the accelerated weathering. The lithology of the suture zone in the Trans-Himalaya is dominated by granites and sediments[9,11].

Ganga, Brahmaputra and Indus are the major river systems of the extrapeninsular region, the first two flowing eastward into the Bay of Bengal and the last into the Arabian sea. Ganga and its tributaries from the Himalaya, Yamuna, Kali, Gandak, Kosi and Ghaghara, drain the Pre-Cambrian crystallines and sedimentary sequences in the southern slopes of the Himalaya, whereas Brahmaputra flows along the Indus Tsangpo suture zone in Tibet before taking a turn at the syntaxial bend and entering the crystalline terrains of the Himalaya[5]. The main tributaries of the Indus system – Sutlej, Beas, Ravi, Chenab (Chandra and Bhaga) and Jhelum – drain the crystalline terrains of the Himalaya in their upper reaches (similar to Ganga and its tributaries), whereas Indus and its northern tributaries, Nubra and Shyok, drain a suture zone lithology in a monsoon shadow region[9].

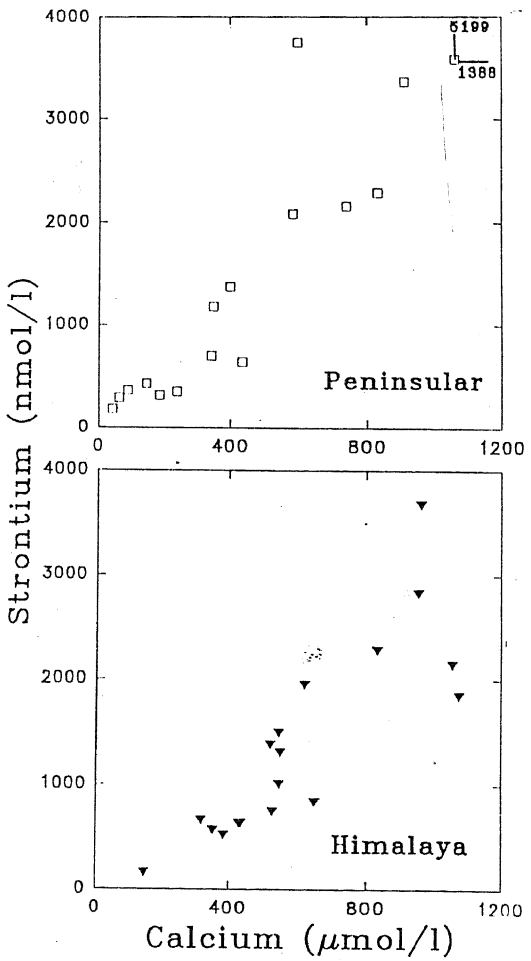

Figure 2. Variation of Sr concentration with calcium in the peninsular and Himalayan rivers. The Sr concentrations generally increase with Ca.

The peninsular rivers are seasonal (monsoonal) in contrast to the Himalayan ones, which are fed by glaciers and are perennial, though their water flux increases considerably during monsoon.

Most of the rivers were sampled during the past several years. The sampling of the Kali–Sarju system (headwaters of the Ghaghra) was carried out recently. The sampling procedures are discussed in detail elsewhere[5]. Briefly, the river waters were filtered through 0.4 μm Nuclepore filters within 5–6 h of collection, acidified to pH~2 with HNO_3 and stored in polyethylene bottles till the time of measurement. Rb and Sr isotope measurements were made in about 50 g of water following isotope dilution mass spectrometric procedures[14]. The weighed water samples were dried with HF/HNO_3, put in HCl and spiked with ^{87}Rb and ^{84}Sr tracers, and dried. The dried residue was taken in 2.5 N HCl and the Rb and Sr fractions were separated on a cation exchange resin (Dowex 50×8, 200–400 mesh). The Rb and Sr fractions were separately dried, taken in a drop of orthophosphoric acid and evaporated directly onto an outgassed tantalum filament of the ion source. The samples were run on a 9″ radius single-focusing mass spectrometer fitted with a Faraday cup collector and the ion current was recorded digitally.

The Sr isotopic ratios were normalized to $^{86}Sr/^{88}Sr = 0.1194$. The long-term stability of the mass spectrometer was checked by measuring the ratio $^{87}Sr/^{86}Sr$ of the NBS-987 standard periodically. The mean $^{87}Sr/^{86}Sr$ of the standard based on nine runs during 1991–93 is 0.71025 ± 0.00005. In addition, to check on the accuracy of $^{87}Sr/^{86}Sr$ measurements we analysed a sea water sample from the Arabian sea and $CaCO_3$ from a living coral from the Lakshadweep. For these two samples $^{87}Sr/^{86}Sr$ are 0.7097 ± 0.0006 and 0.7092 ± 0.0002, respectively, in good agreement with contemporary sea water values. The total Rb and Sr blanks from reagents and chemical procedures are ~5 and ~50 pmol, respectively, much lower than the typical values of about 1 and 25 nmol for Rb and Sr in 50 g water samples. The overall precision on $^{87}Sr/^{86}Sr$ (two standard errors of the mean of about 50 ratio measurements) is about ± 0.0005. These errors are considerably smaller than the scale of Sr isotope variations observed in the river waters analysed. Ca and K measurements were made by atomic absorption spectrophotometry[5].

The dissolved Rb and Sr concentrations and $^{87}Sr/^{86}Sr$ of the water samples analysed are given in Table 1 along with their K and Ca abundances. Table 2 lists the same for the Kali-Sarju system (also known as Mahakali–Sarju) headwaters of Ghaghara, a major tributary to the Ganga. More detailed data on Sr isotopes, Rb and major

ions for the rivers belonging to the Ganga–Brahmaputra and Indus systems are published elsewhere[7,9].

The Kali–Sarju waters were sampled to test if $^{87}Sr/^{86}Sr$ for the headwaters of major tributaries of Ganga, are as radiogenic as of Bhagirathi and the Alaknanda, sampled by us earlier[7]. The results show that the Sr isotope ratios in all these waters are highly radiogenic, and as will be discussed later, such high values probably result from weathering of rich in radiogenic Sr silicates in the drainage basin.

A cursory look at the data in Table 1 reveals that the Sr concentration in the samples ranges between 169 and 5199 nmol/l, similar to that observed for rivers in other parts of the world[2-4].

The Sr concentration shows a general increase with Ca (Figure 2), the correlation being relatively tight for rivers from the peninsular region. The Sr/Ca molar ratios (nmol Sr/μmol Ca) of the peninsular and the Himalayan rivers overlap within the scatter of the data. The mean molar Sr/Ca ratio corresponds to a Sr/Ca weight ratio (g/g) of $\sim 7 \times 10^{-3}$ and $\sim 5 \times 10^{-3}$ for the peninsular and the Himalayan rivers, respectively. The Sr/Ca ratio in rivers is determined by the supply of Sr and Ca to the waters by various rocks and minerals, and their mixing proportions. An important source of Ca to these waters (Table 1) is the weathering of carbonates[5–9]. The Sr/Ca weight ratio in typical carbonates is $1-2 \times 10^{-3}$ (ref. 15). Congruent weathering of carbonates (for Ca and Sr) would yield Sr/Ca ratio in river waters significantly lower than that we have measured. Such an observation (Figure 2) would require that either Sr is mobilized preferentially over Ca from carbonates such that the Sr/Ca ratio in rivers is higher than that in carbonates or that these rivers receive Sr from other sources such as evaporites and silicates from the upper crust, which have Sr/Ca higher than that in typical carbonates. Basalts, granites and shales have Sr/Ca about 3 to 10 times higher than that in carbonates. As discussed below, $^{87}Sr/^{86}Sr$ for these river waters also requires that they derive some of the Sr from a more radiogenic source than typical carbonates, such as silicates of the upper crust.

$^{87}Sr/^{86}Sr$ for the rivers sampled (Table 1, Figure 3) lies in the range 0.7097–0.7589; almost all samples have $^{87}Sr/^{86}Sr$ exceeding the global average estimate of 0.7119 (ref. 2). The data also show that $^{87}Sr/^{86}Sr$ for the peninsular rivers falls within a narrow range of 0.71–0.72 and is generally lower than that for the Himalayan rivers draining the granite/gneiss crystallines. The contrast is more pronounced when the comparison is made with that for the headwaters of Ganga[7] and Ghaghara (Table 2, Figure 3). All the headwater samples analysed, except Kali, have $^{87}Sr/^{86}Sr$ exceeding 0.73, with Sr concentration in the range of 140–1390 nmol/l (Table 2, ref. 7).

$^{87}Sr/^{86}Sr$ of dissolved Sr in rivers is governed by the magnitude of Sr contribution from various source rocks

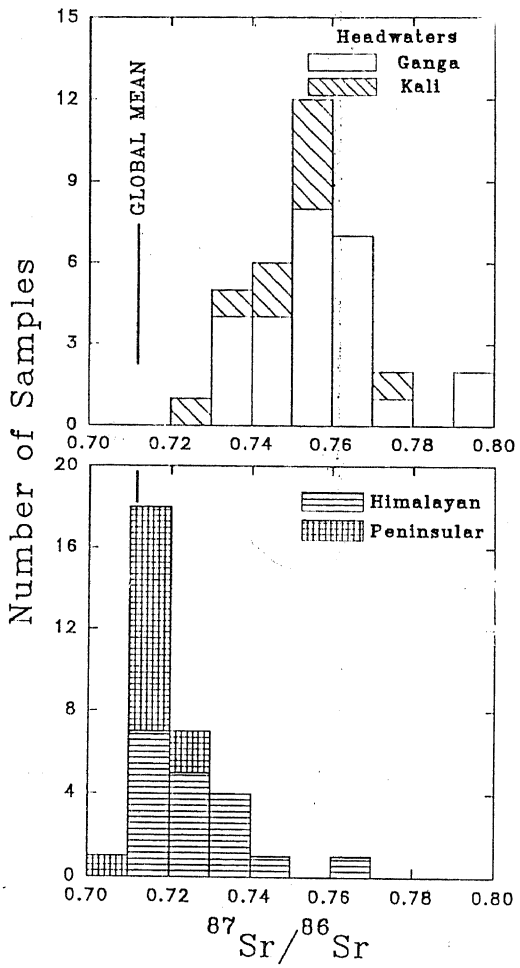

Figure 3. Frequency distribution of dissolved $^{87}Sr/^{86}Sr$ in the rivers sampled. Data for Ganga headwaters from ref. 7 and Kali River (this study). For comparison the data for Himalayan and peninsular rivers from Table 1 are also shown. The distinctly higher radiogenic $^{87}Sr/^{86}Sr$ of the headwaters is evident.

(e.g. carbonates, silicates, evaporites) to the effluent waters and their respective $^{87}Sr/^{86}Sr$. For typical carbonates and evaporites this ratio is constrained within a narrow range of 0.706 – 0.709, whereas that for silicates it can vary widely both within and among various drainage basins. Basaltic terrains set a lower limit on $^{87}Sr/^{86}Sr$ for crustal silicates with values of ~ 0.705. The upper limit on $^{87}Sr/^{86}Sr$ in silicates is less constrained, though values exceeding 1.0 are encountered in individual rock suites, such high values are unlikely to be representative of river basins as a whole.

For all the river waters sampled in this study (Tables 1 and 2) $^{87}Sr/^{86}Sr$ is higher than that for typical marine carbonates, suggesting that at least a part of the Sr in

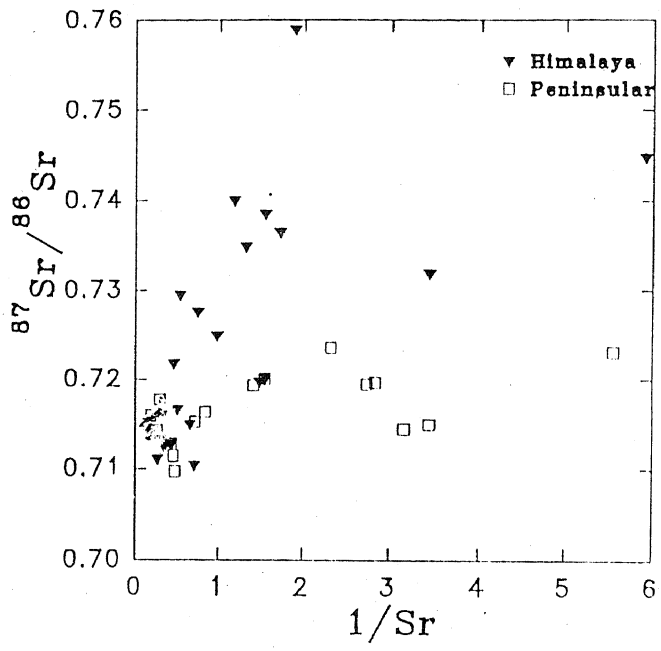

Figure 4. Sr isotope systematics in the rivers sampled. The $^{87}Sr/^{86}Sr$ increases sharply with decreasing Sr concentration in the Himalayan rivers. The peninsular rivers also show a similar trend, but with a gentler slope.

these rivers is derived from a source having more radiogenic $^{87}Sr/^{86}Sr$. The plot of $^{87}Sr/^{86}Sr$ versus 1/Sr (Figure 4) reveals that for the Himalayan rivers there is a steep increase in $^{87}Sr/^{86}Sr$ as the Sr concentration decreases. The peninsular rivers also seem to show an increase in $^{87}Sr/^{86}Sr$ as Sr decreases, but with a much gentler slope. The broad trend in Figure 4 can be interpreted in terms of mixing of Sr between a high $^{87}Sr/^{86}Sr$ end member with a low $^{87}Sr/^{86}Sr$ component (e.g. typical carbonates/evaporites). The relation between $^{87}Sr/^{86}Sr$ and Sr concentration for the Himalayan rivers, particularly those belonging to the Ganga system, are distinctly different from other global rivers, in accordance with our earlier observations and other studies[2,7,9,16,17]. Many of these rivers are characterized by high $^{87}Sr/^{86}Sr$ and high Sr concentrations (Figure 4). The source of such high $^{87}Sr/^{86}Sr$ in these rivers is not clear. Weathering of Pre-Cambrian granites and gneisses[7,9] and rocks and minerals enriched in radiogenic Sr due to regional metamorphism, such as the leucogranites and gneisses[16] and carbonates[17], have been suggested as possible sources of high $^{87}Sr/^{86}Sr$ in these rivers. Studies[18] of $^{87}Sr/^{86}Sr$ in sediments from the Bay of Bengal indicate that the dominant source of these sediments for the past ~17 Ma is the higher Himalayan crystallines. Available data from the drainage basin of the Ganga headwaters and its tributaries show that whole-rock $^{87}Sr/^{86}Sr$ are quite radiogenic, with the bulk of the samples clustering around 0.76 and a significant fraction of the samples having values in excess of 0.90 (Figure 5). Such high $^{87}Sr/^{86}Sr$ in the silicates can account for the high $^{87}Sr/^{86}Sr$ in the headwaters of the Ganga system. However, data on Sr isotope composition of carbonates from the drainage basin are needed to confirm this. Whatever be the source of $^{87}Sr/^{86}Sr$ to Ganga, its high value has considerably influenced the Sr isotope evolution of the oceans since the Cenozoic[7].

The data in Figure 4 show an overall increasing trend in $^{87}Sr/^{86}Sr$ with decreasing Sr, but there is a significant scatter. The scatter within each trend probably reflects heterogenity in the Sr isotope composition of the silicate end member. Such a heterogenity can arise as the Himalayan and the peninsular regions are large geographical areas having lithologically distinct sub-basins which the different rivers drain. The wide range of $^{87}Sr/^{86}Sr$ for the silicates from the drainage basin of the Ganga system headwaters (Figure 5) attests to this hypothesis.

The Sr isotope composition of the peninsular rivers is similar to that reported for rivers from other continental shield areas. The source of high radiogenic Sr to Zuari and Mandovi rivers could be the granites and gneisses in their basin, some of which have $^{87}Sr/^{86}Sr$ of 0.713–1.13 (ref. 19). Periyar and Pambayar flow mainly through granulites; the Sr isotopic analysis on these rocks are meagre, and those which are available are in the range 0.78–0.89 (refs. 20 and 21). Mahanadi and Godavari traverse through Deccan trap basalts, unmetamorphosed sedimentary sequences and the high-grade metamorphic terrain of the eastern Ghats. The measured $^{87}Sr/^{86}Sr$ for these river samples integrates the contributions from all these lithologies. Tapi, flowing mainly through the Deccan trap basalts, has the lowest $^{87}Sr/^{86}Sr$ among all the samples (Table 1).

Based on the Sr concentration and $^{87}Sr/^{86}Sr$ in the peninsular rivers (Table 1) and those reported earlier by us[7,9] for Ganga, Brahmaputra and Indus, the discharge-weighted mean Sr concentration in these rivers is calculated to be ~ 1.5 μmol/l, with a $^{87}Sr/^{86}Sr$ of 0.716. The mean Sr concentration in the rivers of India–Pakistan is higher than the global average value of 0.89 μmol/l[-2]; our sampling of some of the rivers (e.g. Indus) during their lean flow may be a likely cause for the high mean concentration. The discharge-weighted Sr/Ca molar ratio of these rivers is 2.7×10^{-3}, which compares with a value of $\sim 2.2 \times 10^{3}$ for the world rivers (based on Sr and Ca concentrations of 0.89 and 398 μmol/l, respectively). The annual flux of Sr transported by the rivers from India–Pakistan to the ocean is ~2200 million moles if our measurements can be considered representative of these rivers. These calculations show that the rivers from India–Pakistan account for ~6.5% of the global riverine Sr flux to the oceans, with a $^{87}Sr/^{86}Sr$ marginally more radiogenic than the global average.

The influence of anthropogenic effects in modifying the natural Sr flux and its isotopic composition is diffi-

Table 3. Rb, Sr concentrations and $^{87}Sr/^{86}Sr$ in fertilizers

Code	Type	Source	Rb (ppm)	Sr (ppm)	$^{87}Sr/^{86}Sr$*

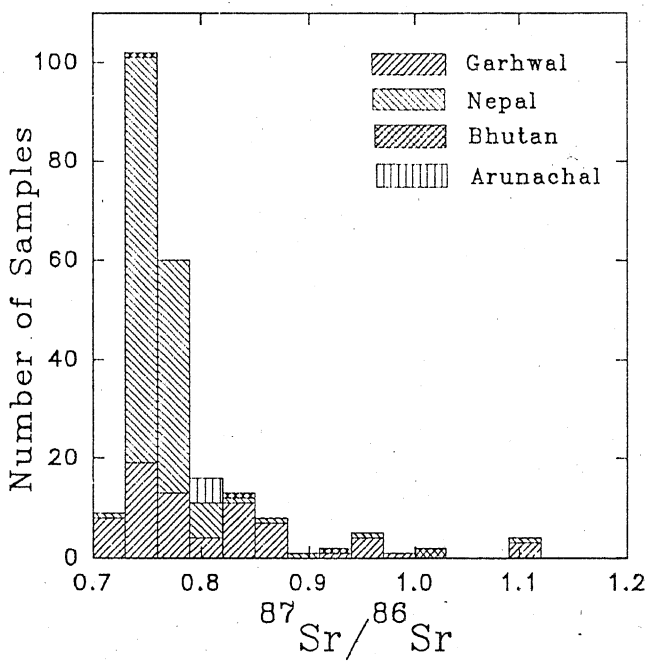

Figure 5. Frequency distribution of $^{87}Sr/^{86}Sr$ in whole-rock samples from the drainage basins of the headwaters of Ganga and its tributaries (Garhwal and Nepal) and Brahmaputra (Bhutan and Arunachal). Data compiled from refs 14, 23–32. The rocks from this region have highly radiogenic $^{87}Sr/^{86}Sr$.

cult to assess. Damming and impounding of rivers may reduce their water discharge, whereas the use of fertilizers may alter the natural Sr concentration of rivers and their $^{87}Sr/^{86}Sr$. We measured the Sr concentration and $^{87}Sr/^{86}Sr$ in a few fertilizer samples used in northern and western India. The results (Table 3) show that all the samples, except for the muriate of potash (MOP), have $^{87}Sr/^{86}Sr$ of ~0.708, consistent with that expected, as bulk of Sr in fertilizers is derived from limestones and phosphates of marine origin. The muriate of potash, which is abundant in potassium and rubidium, has a highly radiogenic $^{87}Sr/^{86}Sr$ of ~0.749 (Table 3). This high value raises concern about the impact such fertilizers can have in enhancing the natural $^{87}Sr/^{86}Sr$ of rivers. Our earlier observation[7] that $^{87}Sr/^{86}Sr$ for Ganga and many of its tributaries varies only marginally during different river stages is an indication that contamination, if any, of natural Sr by fertilizer may not be significant. Moreover, the most radiogenic Sr isotope composition is in the headwaters of Ganga and Ghaghara, where agricultural influences are minimal.

Summing up, our results on the Sr isotope systematics of rivers from India and Pakistan show that almost all the rivers sampled have $^{87}Sr/^{86}Sr$ in excess of the global average, with the headwaters of Ganga and its tributaries having the most radiogenic Sr isotope composition. Studies on the source of radiogenic Sr to the Ganga system (i.e. silicates or metamorphosed carbonates) would help in understanding better the coupling between Himalayan tectonics, weathering and climate change[22].

The non-induction of HSP70 in heat shocked Malpighian tubules of *Drosophila* larvae is not due to constitutive presence of HSP70 or HSC70

Bhupendra N. Singh and S. C. Lakhotia

Department of Zoology, Banaras Hindu University, Varanasi 221 005, India

To understand reasons for the earlier reported non-induction of any of the common heat shock polypeptides in Malpighian tubules of *Drosophila* larvae, we examined the levels of the 70 kDa heat shock polypeptide (HSP70) and of its cognates (HSC70) in control and heat shocked larval tissues, including the Malpighian tubules, by ^{35}S-methionine labelling in conjunction with Western blotting or by immunocytochemical localization using appropriate antibodies against the heat inducible and constitutively expressed members of the HSP70 family. The HSP70 was totally undetectable in western blots of control as well as heat shocked Malpighian tubules of *Drosophila* larvae; the levels of different HSC70 in untreated Malpighian tubules were comparable to those in other larval tissues and also did not increase following heat shock. Immunocytochemical localization of HSP70 showed that none of the highly polytenized cells of Malpighian tubules showed induction of HSP70 after heat shock. The non-induction of the common heat shock proteins in Malpighian tubules of *Drosophila* larvae, therefore, is not due to autoregulation by constitutively high levels of HSP70 or HSC70.

CELLS of virtually every organism respond to a sudden exposure to elevated temperature (heat shock) by transiently increased synthesis of a specific set of polypeptides, commonly referred to as heat shock proteins (HSPs) or stress proteins, which help cells survive the thermal and other damages[1–3]. This response, first discovered in *Drosophila*[4, 5], is a highly conserved biological phenomenon. However, contrary to the general dogma that all cells of an organism respond more or less uniformly to heat shock[1–3], Lakhotia and Singh[6], using ^{35}S-methionine to label the newly synthesized proteins, found that none of the well-characterized HSPs, including the most abundant 70 kDa heat shock protein (HSP70), was induced in heat shocked Malpighian tubules of *Drosophila* larvae. However, the basal levels of HSPs in the Malpighian tubules were not examined in that study[6]. Since synthesis of HSPs is autoregulated, particularly by HSP70 levels[2, 3, 7], the lack of induction of HSPs in heat-shocked Malpighian tubules[6] could be due to a constitutive presence of these proteins in threshold quantities so that further synthesis was inhibited. We have examined this possibility in the present study. Using ^{35}S-methionine labelling in conjuction with HSP70-specific antibodies, we reconfirm the earlier observation[6] on non-inducibility of the common HSPs in this tissue of *Drosophila* larvae and further show that the HSP70 is totally absent, before as well as after heat shock in this tissue; the levels of the various forms of 70 kDa

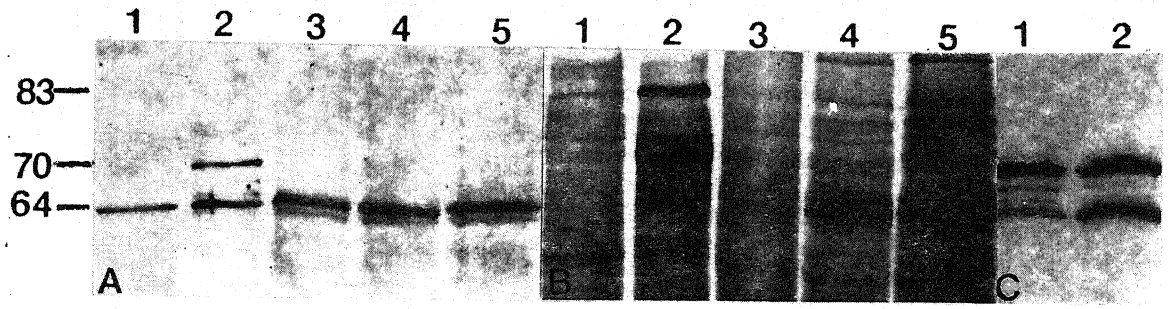

Figure 1. Showing absence of HSP70 in Malpighian tubules of *Drosophila* larvae. ***a***, Western blot of control (lanes 1 and 3) and heat-shocked (lanes 2, 4 and 5) samples of salivary glands (lanes 1 and 2) and Malpighian tubules (lanes 3–5) challenged with the HSP60 and HSP70 (*7Fb*) antibodies; lane 5 has 1.5 times more protein than lanes 3 and 4. ***b***, Fluorogram of the Western blot in (***a***). ***c***, Western blot of a sample of heat-shocked salivary glands alone (lane 1) or of a mixed sample of heat shocked salivary glands and Malpighian tubules challenged with HSP60 and HSP70 antibodies. For details, see text. The molecular sizes (in kDa) of polypeptides are indicated on sides.

heat shock cognate proteins (HSC70)[8, 9] in the larval Malpighian tubules are not higher than in other tissues. Therefore, the non-induction of HSP70 and other common HSPs in Malpighian tubules following heat shock is not due to inhibition by the constitutively present members of the HSP70 family.

A wild-type strain (Oregon R^+) of *Drosophila melanogaster* was used for these studies. The flies and larvae were reared on standard cornmeal–agar–yeast food at 22 ± 1°C.

Different organs (salivary glands, Malpighian tubules, brain ganglia) from late third-instar larvae were dissected in Poels' salt solution (PSS)[10], transferred to fresh PSS in microfuge tubes and were immediately either heat shocked at 37°C for 30 min or were kept at 22°C for 30 min as control. The heat shocked and control tissues were labelled with ^{35}S-methionine (BRIT, Bombay, 200 µCi/ml; sp.act. 1000 Ci/mM) for 30 min at 37°C and 22°C, respectively. Protein samples were prepared in the Laemmli sample buffer[11] and electrophoresed by SDS-PAGE as described[6]. Equal numbers of organs of a given type were taken for control and heat shock samples.

The electrophoresed polypeptides were transferred to nitrocellulose membrane (Schleicher & Schuell, Germany) by semi-dry blotting following the method of Lakhotia and Singh[12]. Two rat monoclonal antibodies, viz. *7Fb* (HSP70-specific) and *7.10* (recognizing the cognates (HSC70) as well as the heat inducible form of HSP70 of *Drosophila*)[13], obtained from S. Lindquist (USA), were used to detect the HSP70 and HSC70, respectively, in western blots at 1 : 1000 dilution. In some cases (Figure 1), the blots were first challenged with an anti-HSP60 antibody (*SPA-805*, Stressgen, Canada) and then with the HSP70-specific *7Fb* antibody. The primary antibodies were detected by using the corresponding HRP-conjugated secondary antibodies (Sigma, USA, or Bangalore Genei, Bangalore) at recommended dilutions. Following the immunodetection, the blots with ^{35}S-methionine labelled samples were fluorographed by dipping in toluene with 22% PPO for 3 min and drying for 1 h at room temperature before exposing to X-ray film to detect radiolabelled newly synthesized polypeptides. The Western blots and the fluorograms were then compared.

For immunocytochemical localization of HSP70, the salivary glands and Malpighian tubules with associated parts of the gut were dissected out from late third instar larvae and incubated in PSS at 22°C (control) or at 37°C (heat shock) for 30 min. Tissues were fixed in 4% paraformaldehyde in PBT (130 mM NaCl, 7 mM $Na_2PO_4 \cdot 2H_2O$, 3 mM $NaH_2PO_4 \cdot 2H_2O$, 0.2% Triton-X-100, pH 7.0) and processed for immunocytochemical localization of HSP70 using the *7Fb* antibody (1 : 200 dilution) and goat anti-rat secondary antibody (HRP conjugate, Sigma) at recommended dilution following the standard procedure[14].

Figure 1 *a* shows a Western blot of control and heat shocked salivary glands and Malpighian tubules from late third-instar larvae challenged sequentially with HSP60-specific (*SPA-805*) and HSP70-specific (*7Fb*) antibodies; fluorogram of the same blot is shown in Figure 1 *b*. Synthesis of all the HSPs was typically induced in salivary glands by heat shock (only HSP83, HSP70 and HSP68 are seen since only the upper half of the gels was always blotted). However, in agreement with the earlier finding of Lakhotia and Singh[6], heat shock to Malpighian tubules resulted in enhanced synthesis of some other polypeptides with a major band at 64 kDa (lanes 3–5 in Figure 1 *b*), but not of any of the usual HSPs (it may be mentioned here that this 64 kDa polypeptide was erroneously estimated as 58 kDa band by Lakhotia and Singh[6]). The *7Fb* antibody, which exclusively recognizes the heat shock inducible form of HSP70 of *Drosophila*[13], revealed the presence of HSP70 only in heat

shocked and not in control salivary glands. Neither the control nor the heat shocked Malpighian tubules showed any trace of HSP70 (lanes 3–5 in Figure 1). That the failure to get a signal with HSP70 antibody in Malpighian tubules was not due to the generally lower amount of proteins in Malpighian tubule samples was evident from the similar extent of labelling seen in the lanes for salivary glands and Malpighian tubules in the fluorogram in Figure 1 *b*. This was further confirmed by deliberately loading a greater amount of labelled sample from heat shocked Malpighian tubules in lane 5 (Figure 1 *a*, *b*); this also failed to reveal any trace of HSP70 in the Malpighian tubules. In addition, the same blot when challenged with an antibody for HSP60, which is constitutively present in all tissues of *Drosophila*[12, 15], showed more or less equal signal in all lanes, except in lane 5, which showed a more intense signal in proportion to the greater amount of protein loaded.

The complete absence of HSP70 in the Malpighian tubules can also not be due to a general failure of heat shock in these samples since the fluorogram clearly showed a significantly increased synthesis of the 64 kDa and other heat inducible polypeptides which are known to be heat shock induced in this tissue[6].

The HSP70 protein of *Drosophila* can decay *in vivo* as well as *in vitro* at a much faster rate: degradation, which is mediated by a proteolytic action of HSP70 protein upon itself, may sometimes occur rapidly, even during the course of electrophoresis[16]. To check that the absence of HSP70 in Malpighian tubules was not due to a tissue-specific degradation of this polypeptide, the Malpighian tubules and salivary glands excised from late third instar larvae were pooled, heat shocked together, dissolved in the sample buffer and run in one lane: Western blot revealed a distinct presence of the HSP70 in this mix (lane 2 in Figure 1 *c*), similar to that in the heat shocked sample of salivary glands alone (lane 1 in Figure 1 *c*). This demonstrated that the Malpighian tubule samples did not specifically lose their HSP70 due to degradation.

The HSP70 protein family in *Drosophila* includes both the heat-inducible (HSP70) and constitutively expressed homologues, the heat shock cognates (HSC70), which exist in several isoforms and show spatial and temporal tissue specificity[8, 17]. *Drosophila* embryos till the blastoderm stage do not synthesize HSP70 after heat shock, but are known to have an HSC70 in abundance[8]. Since it is possible that the total level of HSP70-related proteins in a cell is highly regulated[18], we examined whether the Malpighian tubules of *D. melanogaster* larvae contained higher levels of HSC70, which may prevent induction of HSP70. For this purpose, we used the *7.10* antibody, which recognizes[8, 13] both cognates and heat inducible forms of HSP70. Western blots of samples from different tissues (brain ganglia, salivary glands and Malpighian tubules of larvae), challenged with the *7.10* HSC70 monoclonal antibody, showed (Figure 2) a nearly similar

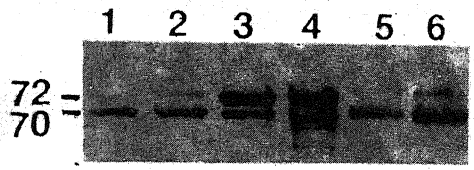

Figure 2. Levels of HSC70 in different larval tissues are similar. Western blot of control (lanes 1, 3 and 5) and heat shocked (lanes 2, 4 and 6) larval brain ganglia (lanes 1 and 2), salivary glands (lanes 3 and 4) and Malpighian tubules (lanes 5 and 6) challenged with the HSC70 antibody (*7.10*). The molecular sizes (in kDa) are indicated on the side.

pattern of reacting bands (68–72 kDa) in control and heat shocked samples of all the tissues. The more intense signal for salivary glands (lanes 3 and 4 in Figure 2) in this blot is due to more protein in these lanes. There was no noticeable increase in the levels of any of the HSC70 polypeptides in control or heat shocked Malpighian tubules (lanes 5 and 6 in Figure 2). This leads us to believe that the non-inducibility of HSP70 in Malpighian tubules is not due to a constitutive presence of high levels of HSC70.

Immunocytochemical staining with the HSP70-specific antibody (*7Fb*) confirmed the absence of HSP70 in Malpighian tubules since while the heat shocked salivary glands (Figure 3 *b*) and midgut (Figure 3 *d*) showed a distinct positive staining with this antibody, cells in control salivary glands (Figure 3 *a*), midgut (Figure 3 *c*) and in control as well as heat shocked Malpighian tubules (Figure 3 *c*, *d*) were negative for the HSP70 antibody. It is notable, however, that while the highly polytenized large cells of Malpighian tubules did not show any staining for HSP70, the fewer, smaller and flatter stellate cells[19] showed heat shock induced presence of HSP70 (see Figure 3 *e*). Apparently, the induced HSP70 in these cells was not enough to be detectable in the Western blots of whole Malpighian tubules. The strong nuclear signal in heat shocked salivary gland cells (Figure 3 *b*) is in agreement with the earlier report[20] that during heat shock the HSP70 concentrates strongly in nuclei.

It may be noted that while preparing the Malpighian tubule samples for electrophoresis, we took extreme care to exclude any part of the midgut to which these organs remain attached *in situ* (see Figure 3 *c*, *d*); we believe that the induction of all the common HSPs in Malpighian tubules of *Drosophila* larvae as reported in an earlier publication[5] was due to contaminating pieces of midgut, which like other tissues shows strong induction of HSP70 (Figure 3 *d*) and other HSPs.

The present results thus reconfirm the earlier report from our laboratory[6] that the Malpighian tubules of *Drosophila* larvae fail to synthesize any of the common

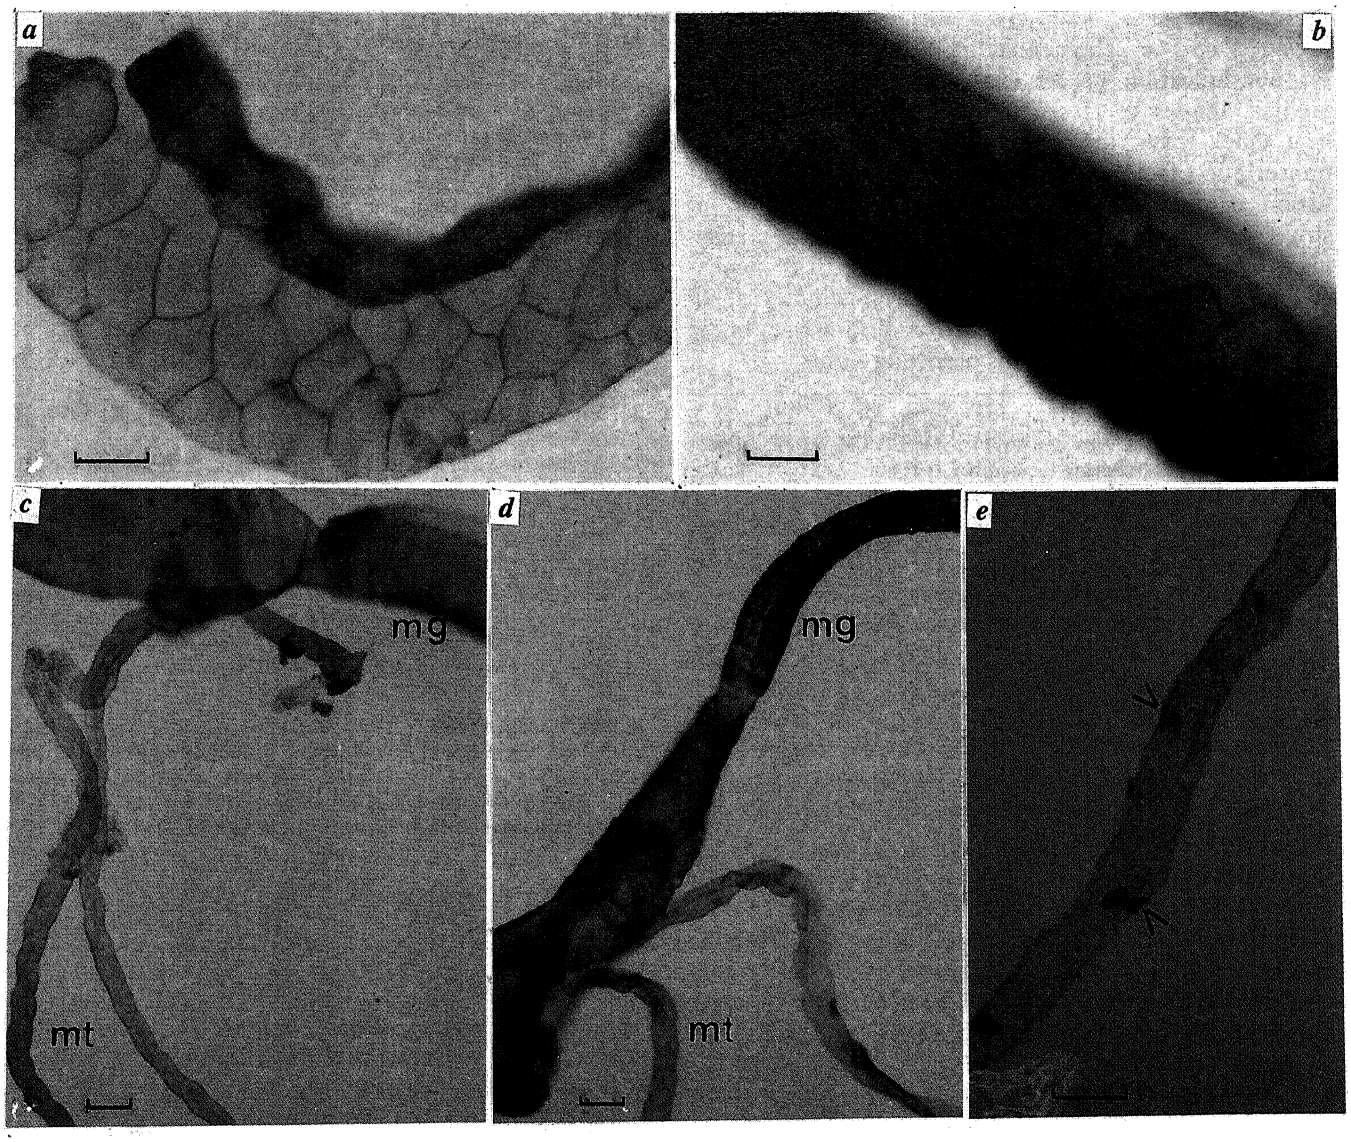

Figure 3. Immunocytochemical localization of HSP70 in control (*a* and *c*) and heat shocked (*b*, *d* and *e*) larval salivary glands (*a* and *b*), midgut (mg in *c* and *d*) and Malpighian tubules (mt in *c* and *d*). Part of a Malpighian tubule is shown at a higher magnification in (*e*) to reveal HSP70 induction in the peripherally located smaller stellate cells (arrowheads). Also note the stronger antibody binding in the nuclei of heat shocked salivary glands (*b*). The scale bars indicate 50 μm.

HSPs in response to heat shock. This study further shows that the non-induction of HSP70 in this tissue is not due to autoregulation[7, 18] by constitutively present HSP70 or HSC70. The same perhaps also applies to non-induction of the other HSPs in this tissue. The only other cell types of *Drosophila* which fail to mount the typical heat shock response are the nurse cells in late stages of oogenesis, oocyte and the pre-blastoderm embryos[21]. However, these cells, unlike the Malpighian tubules, do not show induction of a different set of polypeptides in response to heat shock, and also in these cases the non-induction of the HSPs may be correlated with a constitutively high level[8] of HSC70. Certain types of cells of *Sarcophaga*[22] also do not show synthesis of the typical HSP70 when heat shocked; however, in these cases a different form of HSP70, the HSP65, is induced instead. Unlike in *Sarcophaga*, the 64 kDa HSP induced in Malpighian tubules of *Drosophila* larvae is not a homologue of HSP70 but is a member of the HSP60 family[12, 15].

Several cell types in mammals also differ in inducibility of the HSP70 when heat shocked[23]; however, in most of these cases, unlike the situation in Malpighian tubules of *Drosophila* larvae, only the HSP70 is perhaps affected. Non-induction of the HSP70 in these mammalian cell types has been ascribed to transcriptional regulation by factors other than the heat shock transcription

factor[23]. Thus, compared to the above cases, the heat shock response of Malpighian tubules of *Drosophila* larvae is unique. The regulatory pathways responsible for non-induction of all the common HSPs in Malpighian tubules of *Drosophila* larvae may involve the heat shock transcription factor[24] and/or other auxiliary transcription factors[25] necessary for transcriptional activation of the heat shock genes under conditions of stress. Further studies will help understand the mechanism of this regulation as also the biological significance of this unique situation of non-inducibility of all the common HSPs and induction of a different set in the larger polytenized cells of this particular tissue.

Codon analysis of cyanobacterial genes

S. Krishnaswamy and S. Shanmugasundaram*

Bioinformatics Centre, Department of Biotechnology and *DBT Centre for BGA Biofertilizer, School of Biological Sciences, Madurai Kamaraj University, Madurai 625 021, India

The genes from different species of cyanobacteria have been analysed for relationships both between them and with other microbes and organelles. The codon bias indices indicate that the unicellular *Synechococcus* strain shows a preferred codon usage as those of low expressing genes of *E. coli*, *Agrobacterium tumefaciens* and *S. typhimurium*, whereas the filamentous *Anabaena* sp. and *Fremyella diplosiphon* strains show similarity to yeast (*Saccharomyces cerevisiae*), *Bacillus* sp., *B. subtilis* and *Streptococcus* sp. In so far as the codon bias index can be related to expression levels, the data suggest the possibility of suitable cloning hosts. The filamentous and unicellular cyanobacteria can be clearly separated based on the codon third-position bias and also the correlations involving codon usage. In general, correlations in codon usage profiles point to the filamentous strains being more related to gram positive bacteria and eukaryotes, whereas the unicellular strains are more related to gram negative bacteria.

PATTERNS of codon usage vary between organisms[1] and have helped to understand regulation of gene expression[2, 3]. Several organisms have been examined in detail in terms of their biased codon usage[4, 5]. However, only a preliminary analysis has been reported for codon usage in cyanobacterial genes[6] using a limited set of genes. The relationships within cyanobacterial species and with other organisms have been examined using the compilation by Wada *et al.*[7], who have tabulated the codon usage for different organisms. It must be mentioned that a study of codon usage of different genes from an organism, in spite of potential problems of the pattern of usage[8, 9], can lead to acceptable conclusions in certain cases and provide general trends[6, 7].

The codon usage data were taken from the compilation by Wada *et al.*[7]. These data refer to only complete genes and not to introns. The program CODON was used. This was developed by one of us earlier to examine the relationship of codon usage between plants and

plant viruses[10]. The codon bias index, which determines the level of usage of preferred codons in a gene, has been defined earlier[4]. In this study, the same definition of the codon bias index is used. However, the selection of preferred codons is not based on the percentage occurrence of codons within a set of synonymous codons. The significance of a percentage occurrence depends on the number of synonymous codons. For example, 50% occurrence for a codon is not significant when there are only two synonymous codons but can be considered preferred if there are three or more synonymous codons in the set. Hence, we have calculated the standard deviation in percentage occurrence within the set of synonymous codons for each amino acid. Those codons in a synonymous set whose percentage occurrence is above a given cut-off limit times the standard deviation are flagged as 'preferred'. These preferred codons of the plant, for example, are used to determine if the codons of the plant virus are biased towards the plant codon usage. The best choice of the cut-off limit is one where the minimum number of codons is chosen as preferred while no amino acid is left without at least one preferred codon (Table 1).

In order to compare two codon usage profiles, for each amino acid a correlation coefficient is calculated using the percentage occurrence of codons within the synonymous set. The match coefficient for the entire set of amino acids is then defined as the sum of the weighted correlation coefficients. The weight for each amino acid is calculated as the ratio of the total number of codons for that amino acid to the total number of codons for all the amino acids of the two tables. This is done to take into account the differences in amino acid composition.

Thus,

$$\text{the match coefficient} = \sum_{i}^{N} w_i c_i,$$

where

N = all amino acids except Met, Trp,

w_i = weight factor,

defined as

$$w_i = \frac{\text{total number of codons for the } i\text{th amino acid}}{\text{total number of codons}},$$

and

c_i = correlation coefficient of synonymous codon usage,

$$c_i = \frac{\sum_{j}^{n_i} (p_{ji} - \bar{p}_i)(q_{ji} - \bar{q}_i)}{\left[\sum_{j}^{n_i} (p_{ji} - \bar{p}_i)^2\right]^{1/2} \left[\sum_{j}^{n_i} (q_{ji} - \bar{q}_i)^2\right]^{1/2}},$$

where P_{ji} is percentage occurrence of the jth codon of the ith amino acid of one table, q_{ji} is the percentage occurrence of the jth codon of the ith amino acid of the other table, $\bar{p}_i, \bar{q}_i$ are the means and n_i is the number of codons of the ith amino acid.

The match coefficient as defined here can vary from – 1 (for anticorrelated profiles) to zero (for profiles without correlation) to + 1 (for identical profiles). A high match coefficient indicates that amino acids with a higher frequency of occurrence have a similar distribution of codons within their set of synonymous codons.

The codon usage and the set of preferred codons[10] within the cyanobacterial species – the unicellular *Synechococcus* sp. (SYN), the filamentous *Anabaena* sp. (ANA) and *Femyella diplosiphon* (FDI) – are shown in Table 1. It is seen that the unicellular strain has a different usage from the filamentous strain, unlike in the earlier reported analysis[6]. This is also seen from the third-position codon bias (Table 2), where the unicellular strain has less A, T and more C, G as compared to filamentous strains. The match coefficients (Table 2) also show that there is a low correlation of codon occurrence patterns between unicellular and filamentous strains (0.31 in each case), while between the filamentous strains the coefficient is high (0.93). Thus, the match coefficient is able to provide discrimination between the two types of cyanobacterial strains. A comparison of the cyanobacterial codon usage profiles with those of other organisms using the match coefficients (Table 3) shows that the filamentous and unicellular strains of cyanobacteria also have different relationships with other organisms. This is seen from the unicellular strain having a high match coefficient with the gram negative bacteria *S. marcescens*, *Pseudomonas* sp., *A. vinelandii* and the gram positive *Streptomyces* sp. The filamentous strains have a high match coefficient with the gram positive bacteria *B. megaterium*, *Streptococcus* sp. and the eukaryotic yeast (*Schizosaccharomyces pombe* and *S. cerevisiae*), and with chloroplasts of chlamydomonas, pea, maize, spinach and tobacco. A high match coefficient shows a related pattern of codon occurrence. The above-mentioned difference in the codon usage profile implies that the unicellular and filamentous forms could have different evolutionary branches.

The codon bias index refers to how the preferred codons of other organisms are used in cyanobacterial genes, while the match coefficient is an indicator of the correlation in use of all the codons of cyanobacterial genes and the other organism. Thus, the bias and the match coefficient need not relate to each other as has also been shown elsewhere[10].

The usage of preferred codons in organisms has been related to levels of gene expression though it is known that there are other factors that also affect gene expression levels. A comparison of the codon bias indices of

*Genes with low expression and **genes with high expression.

the cyanobacterial genes with respect to other organisms (Table 4) shows that the codon usage of unicellular genes is biased towards *E. coli* (low expression) and *A. tumefaciens*, whereas the filamentous genes are biased towards *S. cerevisiae*, *Bacillus* sp., *B. subtilis* and chloroplasts. In as far as the biased codon usage is a determinant of the levels of gene expression, it is seen through this analysis that *A. tumefaciens* could form an alternate cloning host apart from *E. coli* for unicellular strains and filamentous strains may be better expressed in *S. cerevisiae*, *Bacillus* sp. or *B. subtilis*. These conclusions are being made to form a basis for molecular biology experiments involving cyanobacteria.

Effects of feeding mulberry (*Morus* sp.) leaves supplemented with different nutrients to silkworm (*Bombyx mori* L.)

A. A. Sarker, M. R. Haque, M. A. Rab and N. Absar*

[1]Bangladesh Sericulture Research and Training Institute, Rajshahi 6100, Bangladesh
*Department of Biochemistry, Rajshahi University, Rajshahi 6205, Bangladesh

The growth of silkworm larvae improved significantly on feeding them mulberry leaves supplemented with different nutrients. The total protein content of silk gland increased, while the water, total lipid and carbohydrate contents decreased. The larval weight, silk gland weight and total protein in silk gland were found to be highest for treatment TS_8 (soymilk + sugar + vitamins + potassium iodide salt), followed by TS_7 (glycine + alanine + sugar + vitamins + potassium iodide salt) and TS_9 (milk powder + sugar + vitamins + potassium iodide salt) treatments. The highest values of single-cocoon weight, single-shell weight and filament length were observed for treatment TS_8 (1.34 g, 0.26 g and 799.42 m/cocoon, respectively), whereas cocoon yield was found to be highest for treatment TS_7 (110.17 g/100 larvae). No significant difference was observed between the treatments TS_7, TS_8 and TS_9, their influence on silk gland and cocoon characteristics being more or less similar. The cocoon yield/100 larvae was increased by 20.61%, 20.38% and 19.06% in treatments TS_7, TS_8 and TS_9, respectively, over the control treatment.

IT has been well established that the silkworm (*Bombyx mori* L.) requires certain essential sugars, proteins, amino acids, fatty acids and vitamins for its normal growth, survival and also for the growth of silk gland and higher production of good-quality silk. The nutritional status of the mulberry leaves can be improved by enriching them with extra nutrients. Fortification of mulberry leaves with extra nutrients like glucose, glycine, egg albumin, molasses, etc., was found to increase the larval growth and improve cocoon characteristics[1, 2].

Feeding the silkworms mulberry leaves fortified with 2% solution of casein or jaggery or urea in tap water did not improve any of the economic cocoon characteristics significantly[3]. Gridhar and Radha[4] reported that supplementation with 10 ppm glycine resulted in higher larval weight, shell weight, filament length compared to control. Alagumalai *et al.*[5] observed that fortification of mulberry leaves with the flours of black gram and red gram bran improved the larval growth and cocoon characteristics. Young larvae reared on 1.5% ascorbic acid enriched mulberry leaves resulted in higher silk length, weight and values[6].

The work was undertaken to study the biochemical composition of silk gland as well as the growth and cocoon production of silkworm *Bombyx mori* L. on feeding mulberry leaves supplemented with different nutrients.

The silkworm race BSRI-85/3 was selected for the study. Normal mulberry leaves were supplemented with different nutrient chemicals (variety BM-3) in the form of aqueous solution as follows:

TS_0 (control): Without supplement
TS_1 : Glycine (0.5%) + alanine (0.5%)
TS_2 : Soymilk
TS_3 : Milk powder (10%)
TS_4 : Sugar (10%)
TS_5 : Vitamin B (0.5%) + vitamin C (1%)
TS_6 : Potassium iodide salt (1%)
TS_7 : $TS_1 + TS_4 + TS_5 + TS_6$
TS_8 : $TS_2 + TS_4 + TS_5 + TS_6$
TS_9 : $TS_3 + TS_4 + TS_5 + TS_6$

Mulberry leaves supplemented with these nutrients in stated concentrations were fed to silkworms from fourth instar of larval stage till spinning since during this period the worms have a more vigorous growth with larger assimilation of nutrients. Worms were reared together in mass beds up to the second larval stage and after second-moult worms were separated in four batches (replication) of 100 worms for each treatment. Worms were fed with mulberry leaves smeared with aqueous solutions of above nutrients just before feeding, at the rate of 5–10 ml solution per 30–50 g mulberry leaves.

The weights of mature larvae were determined by taking the weight of 10 larvae just before spinning, and the other individual quantitative and qualitative cocoon characteristics were determined after the spinning following standard techniques as applied for the assessment of silk cocoons.

Silk gland was isolated in the fifth instar of larval stage. The fourth batch (replication) was used for this experiment. The fresh weight and dry weight of silk gland were estimated gravimetrically. The carbohydrate content[7], total lipids[8] and total proteins[9] were estimated.

Soymilk was prepared according to the methods of Khaleque *et al.*[10] and Sarker and Khaleque[11]. The rearing was conducted (in 1992) following the method of Krishnaswami[12] during the seasons S_1 (February–March), S_2 (May–June), S_3 (August–September) and S_4 (November–December). The temperature and relative humidity of the rearing room were, respectively, 27.30 ± 3.50°C and 67.60 ± 4.90%, 29.60 ± 3.70°C and 73.50 ± 7.30%, 28.40 ± 0.60°C and 84.30 ± 5.20%, 23.65 ± 3.20°C and 69.30 ± 4.10% in different seasons.

The chemical composition of silk gland and the growth of *Bombyx mori* larvae fed mulberry leaves supplemented with different nutrients were studied in four seasons. Table 1 presents the mean larval weight, silk gland weight and the chemical composition of silk gland under different treatments of supplementation over the four seasons. The highest larval weight (3.62 g/individual) and silk gland weight (778.75 mg/larva)

Table 1. Mean weight and chemical composition of silk gland fed on mulberry leaves supplemented with different nutrients

Treatment	Average larval weight (g)	Silk gland weight (mg/larva)	Chemical component of silk gland			
			Water (mg/g wt)	Total protein (mg/g dry wt)	Total lipid (mg/g dry wt)	Carbohydrate (mg/g dry wt)

TS_4	3.09de	656.25bcd	725.45bc	282.34c	617.16bcd	5.84ab
TS_5	3.02e	649.50bcd	724.78bc	287.19c	621.22ab	5.72ab
TS_6	2.99e	627.50cd	726.42b	286.03c	619.41bc	5.71ab
TS_7	3.60a	760.75a	704.38d	342.20a	604.13de	5.42b
TS_8	3.62a	778.75a	700.48d	343.21a	606.27cde	5.39b
TS_9	3.60a	741.50a	701.08d	340.87a	601.82e	5.35b

Figure(s) followed by the same letter(s) are not significantly different at 1% level as per Duncan's new multiple range test.

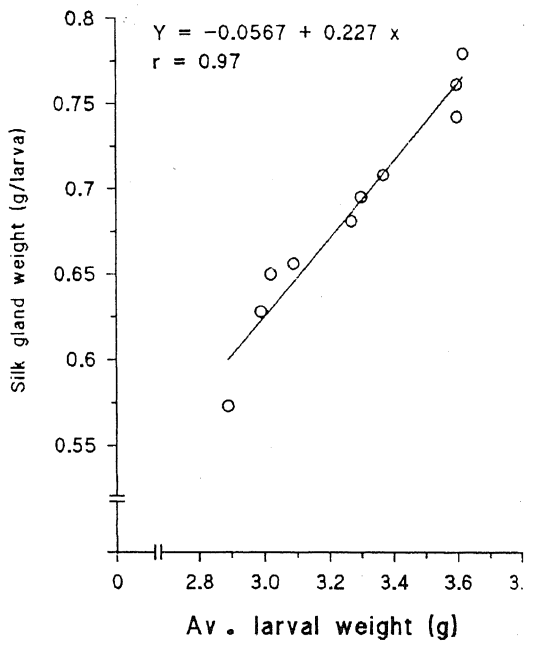

Figure 1. Mean larval weight as a function of silk gland weights.

were observed on feeding mulberry leaves subjected to treatment TS_8, followed by TS_7 (3.60 g and 760.75 mg/larva, respectively) and TS_9 (3.60 g and 741.50 mg/larva, respectively). The protein content of silk gland increased while the water, total lipid and carbohydrate contents of silk gland decreased significantly due to supplementation of mulberry leaves with different nutrients. The highest total protein (343.21 mg/g) content of silk gland was noticed on feeding mulberry leaves subjected to treatment TS_8, while the water (736.85 mg/g), total lipid (634.35 mg/g) and carbohydrate (6.02 mg/g) contents silk gland were found to be highest in the control treatment (TS_0). It may be seen from the Table 1 that the values for larval weight, silk gland weight and chemical components of silk gland on feeding mulberry leaves subjected to treatments TS_7, TS_8 and TS_9 are more or less similar and did not vary significantly.

The mean larval weight was plotted against silk gland weight and the regression line was fitted by the method of least squares (Figure 1). From statistical analysis the correlation coefficient was found to be positive ($r = 0.97$), which indicates that as the larval weight increases the silk gland weight increases.

Mean cocoon characteristics under different treatments of supplementation over four seasons are presented in Table 2. It is seen from the table that single-cocoon weight, single-shell weight, cocoon yield and filament length increased significantly by feeding mulberry leaves supplemented with different nutrients. All the cocoon characteristics were found to show the

Table 2. Mean cocoon characteristics of BSRI-85/3 race fed on mulberry leaves supplemented with different nutrients

Treatment	Single-cocoon weight (g)	Single-shell weight (g)	Cocoon yield/100 larvae (g)	Filament length (m/cocoon)

TS_8	1.34a	0.26a	109.96a	779.42a
TS_9	1.32abc	0.25ab	108.75a	771.58abc

Figure(s) followed by the same letter(s) are not significantly different at 1% level as per Duncan's new multiple range test.

maximum improvement on feeding mulberry leaves subjected to treatment TS_8 except for cocoon yield, which was found to be highest for treatment TS_7. The lower cocoon yield in treatment TS_8 might be due to the higher mortality. However, no significant differences were observed between the treatments TS_7, TS_8 and TS_9 in respect of the cocoon characteristics of silkworm *Bombyx mori* L.

Supplementation with amino acids like tyrosine, phenylalanine and alanine improved the leaf quality of mulberry[13]. Sengupta *et al.*[1] reported that the silk content was more with 1% ascorbic acid in the diet of the silkworms. Babu *et al.*[6] observed that the first and second instar larvae reared on 1.5% ascorbic acid enriched mulberry leaves resulted in higher silk length, weight and denier values. Salts of potassium and calcium have been found to have significant effect on the growth of the silkworm. The addition of amino acids in low concentrations gave the best results regarding weights of larvae, percentage of silk gland, crude protein, cocoons and cocoon shells[14]. Beneficial effect of feeding sugars to larvae of the *Bombyx mori* silkworm was noted by Ito[15]. Fortification of mulberry leaves with the flours of black gram bran and red gram bran increased the larval weight, silk gland weight and improved cocoon characteristics like cocoon weight, shell length, cocoon length,cocoon width, shell ratio and also the reproductive parameters[5]. Observations made during this experiment corroborates these findings to a great extent. The supplementation with glycine + alanine + sugar + potassium iodide salt + vitamins (treatment TS_7), soymilk + sugar + potassium iodide salt + vitamins (treatment TS_8) and milk powder + sugar + potassium iodide salt + vitamins (treatment TS_9) significantly improved the larval weight, silk gland weight, chemical composition of silk gland and cocoon characteristics of *Bombyx mori* (Tables 1 and 2). Cocoon yield/100 larvae was increased by 20.61%, 20.38% and 19.06% with treatments TS_7, TS_8 and TS_9, respectively, over the

control (no supplementation). These might be due to the presence of increased amounts of proteins/amino acids and other nutrients in mulberry leaves which contributed to the extra growth of the silkworm, thereby increasing the weights of larvae and silk gland and improving the cocoon characteristics of *Bombyx mori*.

There existed a positive correlation ($r = 0.77$) between silk gland weight and larval weight in the fifth instar larvae fed on mulberry leaves supplemented with different nutrients. Opender *et al.*[16] and Devaiah *et al.*[17] observed that the rate of increase in silk gland weight is proportional to the rate of increase in the body weight of silkworm. It has previously been reported that the ratio of the two rates was constant throughout the fifth instar[18]. The present study also confirms these results.

The significant decrease in the water, total lipid and carbohydrate contents and the increase in the total protein content in silk gland indicate the qualitative and quantitative improvement of silk gland due to feeding mulberry leaves supplemented with different nutrients, subsequently reflected in the improved cocoon characteristics of *Bombyx mori* L. However, further studies are needed on large-scale level before transfer of technology to the field.

Received 15 November 1994; revised accepted 23 May 1995

The Guide to the Galaxy. N. Henbest and H. Couper. Cambridge University Press, Cambridge. 1994. pp. 265. Price: £35/$49.95 (hardbound); £17.95/$24.95 (paperback).

The last two decades have seen great advances in astronomical colour photography and in computer-generated images of data obtained at all wavelengths from both ground-based and space observatories. These made possible the appearance of 'picture books' in astronomy, of which there have been several in recent years. Apart from adorning coffee tables, which they do very well, such publications serve to convey to nonastronomers some idea of the great beauty there is in the heavens albeit inaccessible to the unaided eye. They also transmit some of the excitement surely felt by the astronomers in the difficult and time-consuming process of creating such images. Even more useful is the role that such books can play in arousing the interest of the young, if not in pursuing a career in astronomy, at least to learn of some of its wonders. The book under review has gone much further and could well become a Bible for the amateur astronomer who really wants to know what he or she is looking at whether through a small telescope, or binoculars, or just gazing at the night sky.

A short description of the book on the flyleaf reads:

'Nigel Henbest and Heather Couper take us on a personal tour of the Milky Way in this delightful guide to our home Galaxy. This book is written in non-technical language, for the general reader and the amateur astronomer. The lucid text is supported by a dazzling portfolio of colour photographs of stars, star clusters and gas clouds in the Milky Way. Specially created maps locate the hundreds of tourist spots visited in this journey through space.

The guide introduces the nature and structure of our Galaxy as a whole. All types of objects that it contains are then described. These include mysterious black holes, the giant globular clusters of stars, every kind of star, regions of star formation, exploding stars and their remnants and the enigmatic objects at the galactic centre, as well as the giant halo surrounding the Galaxy.'

That is accurate as far as it goes, but there is more to the book than that. On the very first page the authors call their effort 'a celebration of the first clear, panspectral view of our own star-city . . ., a book that could not have been written until now'. Putting together what we have seen through all the astronomical windows from radio to gamma rays, the authors succeed in presenting a 'holistic' picture of our Galaxy illustrated with maps that really 'could not have been drawn up even a few years ago'.

Scattered all through the book, and particularly in the early chapters, are engaging accounts of how certain profound discoveries and advances came to be made by the great names in the history of astronomy. A score of portraits/photographs of particular individuals starting with Galileo adds to the character of the book, much credit for which must surely go to Michael Marten, the picture editor.

The word 'Guide' in the title of the book is serious. The book is aimed at the genuinely interested visitor to the Galaxy and not the kind of tourist that would like to do the Taj Mahal in ten minutes and get back to the hotel. Adopting a geographical approach the authors lead the reader firmly by the hand through the highways and byways of our Milky Way system and keep feeding more information than any intelligent lay reader could ever absorb in one go. The maps, which are brightly coloured, are innovations and contain a lot of information obtained from a variety of sources, much of it in very recent years. There are a great number of large boxes which I found somewhat distracting at first; in retrospect, however, I feel that the number of topics covered could not have been handled otherwise. Indeed, I find it amazing how much astrophysical knowledge has been touched upon as and when relevant to whatever object in the Galaxy or phenomenon in the sky was being described.

Everything said above could well be called praise. Is there any criticism I have of this fine book? Almost nothing as far as the content is concerned, but there were a few places where the choice of words grated a bit. An example of such infelicity is (p. 125): 'Determined to punish Orion's chutzpah, Hera . . . . . '. Something else which appeared more than once is, . . . star X or black hole Y or whatever weighing '*in at*' so many Suns, pp. 205, 245, etc. Astronomical objects are not boxers or jockeys and the authors could please remove the prepositions in future editions.

To sum up, *The Guide to the Galaxy* is a must for the serious amateur, a worthwhile acquisition for any scientific library and even for the professional astronomer, a source of information outside one's own area of specialization.

V. RADHAKRISHNAN

Raman Research Institute, Bangalore 560 080, India

Crustal Evolution of Singhbhum – North Orissa, Eastern India. A. K. Saha. Memoir 27, Geological Society of India, Bangalore. 1994. pp. xii + 341. Price: Rs. 350.00; $50.

The Precambrian terrain of Bihar–Orissa has attracted the attention of Indian geologists for more than a century, probably because of the presence of rich mineral deposits. The work of Dunn[1,2], Jones[3], Krishnan[4] and Dunn and Dey[5] laid down the basic framework of the geology of this region. Since the middle part of this century, there has been a spurt of research activity on structural, petrological, geochemical and geochronological aspects and the new work has greatly enriched our knowledge on this important segment of the Indian shield. Saha and his group have been in the forefront of this modern research and several of our current notions stem from their work. Saha has drawn on his vast experience in writing this monograph on the geology of Singhbhum–North Orissa, which would remain a standard work of reference for many years to come. In a book of this type the author's own perceptions are bound to come out strongly in the writing, though Saha has made conscious effort to refer to opposing viewpoints. As the title of the book indicates, he has attempted to integrate the information coming from different lines of study to build a model of Precambrian crustal evolution of this terrain.

Chapter 1 places the Singhbhum region in the perspective of the Indian shield by highlighting the salient points about the evolutionary history of the different Precambrian provinces. No mention is, however, made about the Precambrian sedimentary basins, e.g.

the Vindhyans and the Cuddapahs. A brief summary of the current status of our knowledge on the Singhbhum–North Orissa region in Chapter 2 is followed by the chapter describing the regional structural framework of the terrain. The work of R. K. Verma and his coworkers on the gravity field is summarized. Upper crustal structures interpreted from the gravity data are described. The thermal model for the formation of the West Singhbhum Iron Ore Basin is discussed in some detail. However, one of the major tectonic problems of this region, namely the structural relations between the North Singhbhum fold belt and the Singhbhum Granite Complex and the Iron Ore Basins, is not thoroughly discussed. It is stated that the Archaean nucleus subducted southward below the Granulite Belt, but no firm supporting evidence is offered, nor is there any attempt to explore how this southward subduction fits with the supposed northward subduction along the northern boundary. A convincing demonstration of the subduction of an Archaean (>3.2 Ga) cratonic nucleus below another plate during the Proterozoic would have been of great geodynamic interest.

Chapters 4–8 describe the different units in the Archaean craton: Older Meamorphic Group and Older Metamorphic Tonalitic Gneiss, Iron Ore Group, Singhbhum Granite, Bonai Granite, Nilgiri Granite, and Pallahara Gneiss. Saha and his group have carried out sustained work on these rocks and the chapters contain a wealth of information, particularly on field relations, petrography and geochemistry. The structural geometries in the different units are described and the evidences for inferring the relative ages of the supracrustal and granitoid rocks are cogently discussed. Modal and chemical (major, trace and REE) analyses of the different rock types provide valuable documentation. Interesting new results on the petrogenesis of the granitic rocks are presented. These are based on petrogenetic modelling from geochemical data, a novel exercise in Indian Precambrian geology. Such studies provide important constraints in building up tectonic models.

Chapter 9 summarizes the available data on the geochronology of these rocks. The author has emphasized the importance of multiple methods of dating. However, for a region of such complexity the dates are too few and the picture that emerges is rather confusing. Some of the dates are interpreted as metamorphic dates, others as ages of crystallization while still others are thought to represent partially reset ages. However, no clear rationale for such deductions are presented. It is disquieting that Saha is adhering to the idea of 3.8 Ga old OMTG despite the fact that Basu and his coworkers could not reproduce their earlier isochron. In a recent publication Sharma *et al.*[6], have repudiated their earlier conclusion and have upheld the *ca.* 3.3 Ga age of the OMTG. It is fairly certain that the OMTG is at least 3.3 Ga old and during the next one billion years there were several episodes of granitic activity. But much more work needs to be done to discriminate geochronologically all the different events: the 3.8 Ga emplacement age of OMTG is still to be established convincingly.

Chapters 11–14 deal with the Proterozoic fold belt of North Singhbhum. The broad structural features and metamorphic pattern are described, though no reference is made to some new contributions on structure and metamorphism in the belt, for example, Bhattacharya[7], Bhattacharya *et al.*[8], Chakraborty and Sen[9], Mukhopadhyay *et al.*[10], and Roy[11]. The Dalma volcanic belt is described as a synclinorium though there is no structural evidence in favour of this idea nor are there any data to suggest that the supracrustal sequences north and south of the volcanic belt are equivalent. A welcome inclusion is the sedimentary facies analysis of a part of the Chaibasa Formation. There is an excellent treatment on the geochemistry of the volcanic rocks, particularly the Dalmas and the Dhanjoris. The compilation of the chemical parameters of the different metabasic suites, the granitoid rocks and the other intrusive rocks would be useful for all earth scientists interested in this belt. Petrogenesis of the Mayurbhanj Granite has been discussed in some detail using mass balance calculations.

Chapter 17 describes the major thrust zones in the region, the most important of which is the Singhbhum shear zone. The author has preferred to use the term Copper Belt Thrust, though it is a ductile shear zone several kilometers wide and no discrete thrust surface can be mapped. The thrust is stated to grade into a high-angle gravity fault in the west (p. 177), but there is no structural indication of gravity faulting. There are scanty structural data on the Northern Shear Zone and even less on the Sukinda Thrust Zone.

The author's synthesis on the Precambrian crustal evolution of the Singhbhum–North Orissa region is summarized in Chapter 19. It is implicit from his discussion that the model is not tightly constrained. There are many gaps in our knowledge, some of which the author has highlighted; these need to be bridged before we arrive at a fuller understanding of this part of the Indian Shield.

A large number of well-drafted maps and diagrams supplementing the text have added to the value of this monograph. Unfortunately, many of the localities referred to are not marked on the geological map (Figure 2.3) nor are their latitudes–longitudes given. Some mistakes have been noticed in the list of references.

The monograph presents a fairly balanced view of the existing state of our knowledge on the different aspects of the geology of this terrain. The wealth of petrological and geochemical data culled from different sources and the exhaustive bibliography are the main attractions of this volume. It should find a place in the bookshelf of all serious students of Precambrian geology.

Annual Review of Phytopathology, 1994. R. James Cook (ed.), Annual Reviews Inc., 4139 El Camino Way, Palo Alto, California 94303-0897, USA. Vol. 32. 639 pp. Price: USA $49, elsewhere $54.

As a professional plant pathologist, the reviewer himself has been an avid and regular reader of this review series and has all the volumes in his own library. This series has been popular with plant pathologists all over the world because of its wide coverage of topics, ranging from historical to those covering the cutting edges of the science of plant pathology. Many topics chosen are of international interest. Volume 32 once again follows the rich tradition.

The volume has 30 review topics classified into 13 groups: Prefatory chapter; Pioneer leaders; Diagnosis and appraisal of plant disease; Pathogens: Fungi; Pathogens: Bacteria; Pathogens: Nematodes; Pathogens: Viruses; Physiology, morphology, anatomy, biochemistry and molecular biology of host–pathogen interactions; Epidemiology and influence of climate; Toxicants and chemical control; Biological and culture control; and Special topics.

The first two groups – Prefatory chapter and Pioneer leaders – relate to historical aspects. There is only one article under the first group written by Dr George A. Zentmeyer about his own 55-year innings as a professional pathologist. It is very readable and particularly useful to young plant pathologists, who could learn from the varied, exciting experiences narrated by the author. The second group has three articles on three pioneers in the field of plant pathology – Harry Marshall Ward, Tom Goodey and Frederick Charles Bawden – all from the United Kingdom, whose work has had tremendous impact internationally. There is an interesting account of how the rust disease of coffee wiped out the crop from Sri Lanka and was replaced by tea towards the end of the last century, despite efforts by experts like Harry Marshall Ward. Tom Goodey is today considered the father of nematology in Britain. Bawden's contribution to the field of virology in 1930s has been a landmark; he and his colleague Pirie provided for the first time evidence that viruses are nucleoproteins. All the three articles make very interesting reading.

The third group, Diagnosis and appraisal of plant disease, contains three articles. The first one deals with ash (*Fraxinus* spp.) yellows disease, the second with dogwood (*Cornus* spp.) anthracnose, and the third with the so-called beech (*Fagus* spp.) bark disease. The three articles will be of interest mostly to the scientists of North America and possibly Europe and other temperate regions.

The next four groups cover topics related to fungi, bacteria, nematodes and viruses as pathogens. There is a very interesting review on the presence of double-standard ribonucleic acids (dsRNA) in the rust fungi. The presence of dsRNA seems to be a normal feature of most rust fungi even though these fungi continue to be damaging pathogens of crop plants. In the next few years the role of dsRNA in the pathoginicity of rust fungi should become clear. Another article describes the molecular biology approach that might help in improving our taxonomic understanding of *Rhizoctonia*. There is an excellent review on our status of knowledge regarding the secretion of extracellular virulence factors by phytopathogenic bacteria. Another review worth reading is the one by Sijmons *et al.* highlighting the recent advances made in the areas of parasitic strategies and host cell responses. Again, modern molecular biology techniques have helped and will further help in improving our understanding of the host–root nematode interactions. Modern molecular biology techniques have contributed in rapidly improving our understanding of plant viruses. There is an interesting review on the evolution of closteroviruses, which are known for having by far the largest positive-strand RNA genomes among RNA viruses of plants. Another excellent review covers the topic of plant viral RNA synthesis in cell-free systems. Though our knowledge of initial stages of virus multiplication in plant hosts has increased substantially in the last two decades, it is far from being complete. Another review discusses our recently gained knowledge of RNA–RNA recombinations and evolution in virus-infected plants. Seed transmission of viruses concerns plant pathologists all over the world and this volume has an excellent review discussing the work mainly done in the last 25 years. Another review covers our knowledge of the role of plasmodesmata in viral transport in plants. Though annual reviews are normally edited very well, it is difficult to understand how the editors made the mistake of including the review on the molecular systemics and population biology of *Rhizoctonia*, a fungus, in the group of articles on bacteria.

In the remaining groups of reviews, the readers will find articles dealing with topics like (i) early events in the activation of plant defence response, (ii) social and political implications of managing plant diseases with decreased availability of fungicides in the USA and Europe, and (iii) the role of plant clinics in disease diagnosis and education in North America.

The volume includes a thoroughly prepared subject index. The reviewer is once again convinced about the outstanding service that the volumes of the *Annual Review of Phytopathology* provide to plant pathologists of the world.

Professor Willy Fowler (1911–1995) – An obituary

William Alfred Fowler, Nobel Laureate (1983), passed away on 14 March 1995 in Pasadena, California, the place where he had worked for about six decades. He was better known to all his friends as 'Willy'.

Born on 9 August 1911 in Pittsburgh, Willy Fowler did his first degree at the Ohio State University and then in 1933 went to the California Institute of Technology as a graduate student of Charles Lauritsen at the newly established Kellogg Radiation Laboratory. With so much nuclear astrophysics that has come out of Kellogg, it is interesting to know that the lab had been established to study the physics of 1 MeV X-rays and their application to the treatment of cancer. As Willy recalled in his Nobel Lecture, the change of direction came right at the beginning with the discovery in 1932 by Walton and Cockroft that nuclei could be disintegrated by protons accelerated to energies below 1 MeV. This led Lauritsen to convert one of his X-ray tubes to a positive-ion accelerator and to initiate work in nuclear physics.

The shift towards astrophysics took place in Willy's postdoctoral career at Caltech, where, in fact, he remained throughout his life. His early work with his colleagues at Kellogg included the study of the proton–proton chain and the carbon–nitrogen cycle for making helium from fusion of hydrogen. Kellogg provided data on the many experimental cross-sections for the intermediate reactions in these processes. The fusion process from light to heavier nuclei, however, encounters a stumbling block beyond helium (atomic mass 4).

There is a mass gap from 5 to 8 showing a lack of stable nuclei in this mass range and this was the subject of Willy's study for several years. In the end it became clear that because of this gap the grand scheme proposed by George Gamow of synthesizing all nuclei in the early hot era of the big bang universe would not work. How then were heavier nuclei like carbon and oxygen, or iron, made? Astrophysicists building on the pioneering work of Eddington in the 1920s and Bethe in the late 1930s expected the answer to come from stars. But here also, how was the mass gap to be bridged?

The clue to this question came from a highly imaginative solution proposed by Fred Hoyle in 1953, which was to bring Hoyle and Fowler together in a very fruitful collaboration in nuclear astrophysics, a collaboration that lasted nearly 30 years. It was Hoyle's conjecture that the element-building process would more naturally take place inside stars whose cores were known to be hot enough to sustain nuclear fusion reactions. And to bridge the mass gap after helium, Hoyle proposed that the process would jump over the unstable gap. Thus, three nuclei of helium (atomic mass 4) would fuse to make carbon (atomic mass 12) in a resonant reaction. Resonance would make the triple fusion go fast, to compensate for the rarity of three nuclei coming together.

Willy used to recall how Fred walked into Kellogg with this idea which led to the verifiable result that there ought to exist an excited level of the carbon nucleus to which the three helium nuclei get converted. Look for it, he urged the nuclear physicists. After an initial scepticism, Ward Whaling and others at Kellogg got going and did indeed succeed in confirming Hoyle's conjecture. As the helium nucleus is called the alpha particle, this process came to be known as the *triple alpha process*.

This episode led Willy firmly and irrevocably into astrophysics, where plenty of challenges existed for nuclear physicists, especially in the area of stellar evolution. Eddington's work had shown the way of constructing stellar models essentially for the main sequence stars, whose energy is generated from the fusion of hydrogen to helium. What next? Hoyle's triple alpha process had opened the way for the synthesis of even heavier nuclei. But information on the various reaction rates was lacking. Willy turned his attention to this problem.

While Hoyle provided the theory on stellar structure, Fowler brought the nuclear physics inputs. Still lacking were the theoretical and observational details on how radiation interacts with matter as it escapes from the stars. The husband and wife team of Geoffrey and Margaret Burbidge provided this help in a fourfold collaboration that came to be known as the B^2FH, which culminated in 1957 in a mammoth paper entitled 'The synthesis of elements in stars' in the *Reviews of Modern Physics* (**29**, p. 547). This B^2FH was to set the tone for all future work in stellar nucleosynthesis, for it covered the synthesis of different nuclei in stars in all their different stages of evolution.

From the late fifties to the mid-sixties the Hoyle–Fowler combination turned from stellar setting to the larger extragalactic one. Radio astronomy was beginning to provide glimpses of the highly energetic extragalactic world. Geoffrey Burbidge had been the first one to draw attention to the fact that taken at face value the powerful radio sources demanded huge energy reservoirs that far exceeded the dynamical energies of colliding galaxies. Some new source was needed. Would the stellar option, say, of a supermassive star work? Fowler and Hoyle considered the models of such objects and came to the conclusion that these objects will have a far more dominating force to contend with, namely, the force of gravity. Under such a force these objects would tend to shrink faster and faster. In a paper in *Nature* in early 1963 (**197**, p. 533) they conjectured such highly collapsed supermassive objects as likely sources of the observed energy.

Parallelly, the observational front was also progressing and, thanks to a rare collaboration between the optical and radio astronomers in 1962–63, the first discovery of the quasistellar objects (QSOs) was made. Almost star-like in appearance the QSOs showed large redshifts in their spectra and theoretical estimates led to the conclusion that

energy comparable to that of an entire galaxy might well be coming out of a source no greater than a light year across. Here then was the very example of the kind of objects conjectured by Hoyle and Fowler.

This discovery opened up a new field in astrophysics, called *relativistic astrophysics*, which dealt with the astrophysical phenomena in strong gravitational fields, in situations where Newtonian gravity must be replaced by Einstein's general theory of relativity. So great was the excitement amongst the astronomical community that an international symposium was held in December 1963 in Dallas to discuss the implications of theories and observations in this emerging field. Both Hoyle and Fowler were the lead speakers in this meeting on the theoretical side. These meetings now continue to be held biennially under the title 'Texas Symposia'. Much of the present black hole bandwagon in astrophysics has its origin in the Hoyle–Fowler work of 1963.

Another of Willy's seminal contributions came in the big bang cosmology when in 1967 he along with Fred Hoyle and Robert V. Wagoner carried out a revised and updated version of Gamow's primordial nucleosynthesis. The Wagoner–Fowler–Hoyle paper in the *Astrophysical Journal* (**148**, p. 3) again turned out to be a trendsetter for future work in big bang nucleosynthesis. It is interesting to recall that this work was carried out in a shed in the Cambridge Observatories while Hoyle's new institute building was under construction.

It was during the first six years of the Institute of Theoretical Astronomy at Cambridge that Willy was a frequent visitor during the summer months. He and Fred would sometimes take off to the Scottish Highlands for hiking, a practice that Willy continued till late in his life.

For his work in nuclear astrophysics Willy Fowler shared the 1983 Nobel Prize with S. Chandrasekar. It was the second time that a Nobel award was given for theoretical astrophysics, the previous occasion being in 1967 when Hans Bethe was honoured for his work on stellar structure models with nuclear energy generation. The 1983 award, however, brought both surprise and disappointment at the omission of Fred Hoyle from the list.

Willy was known for his thoroughness in all the work he did, a fact which was belied by his informality and jolly demeanour. He would be the life and soul of a party discussing (over a martini) either the world series, or the Scottish terrain, or one of his long train journeys (he was a train buff), or nuclear cross-sections all with equal ease. Amongst his many honours, his Indian connection was with IUCAA as one of its Honorary Fellows, and several of us recall his jokes and anecdotes as he talked about his latest work in cosmology in March 1990. As a personality he will be greatly missed but his work will continue to guide the succeeding generations of astrophysicists.

Willy Fowler is survived by his wife Mary Dutcher Fowler and two daughters by his first wife Ardienne (deceased).

JAYANT NARLIKAR

Inter-University Centre for Astronomy and Astrophysics,
Post Bag 4, Ganeshkhind,
Pune 411 007, India

GENERALIA

Who should look at stars*

Ashok S. Ganguly

In January 1994, I met Jayant Narlikar on a flight from Calcutta to Bombay. He then reminded me of an earlier occasion when (in a weak moment), I had agreed to deliver a Foundation Day lecture at his Institute in Pune. I tried to wriggle myself out of the commitment, firstly, by reminding Jayant that I would have nothing meaningful to say to what was likely to be a distinguished gathering of scholars, and secondly, because my daughters were discouraging me from being typecast as a Foundation Day fixture. Both attempts failed, as you will notice from my presence here today.

Having made the commitment to speak, I spent many agonizing evenings trying to focus on a suitable topic. Finally, I drew inspiration from my association with Narlikar as a member of the Science Advisory Council to the Prime Minister (1986–89) and settled on a 'blue sky' approach. More of that shortly.

A few recent events spurred me to put down some initial thoughts on paper before I lost track of them. A very close friend and his wife were visiting us in London. While we were driving to Glyndebourne to attend a performance of the Opera, Don Giovani, I shared with them my dilemma about the Foundation Day lecture. My friend's wife, a well-known physician from Bombay in her own right, asked me, 'Why should a poor country like India, with its impoverished millions, fund research to watch stars?' For the best part of the two-hour car ride, we had a series of disagreements on the subject. These disagreements ranged from the concept of curiosity, through the nature of the Indian mind and the need to be part of the international community in leading-edge science, to the origins of the universe and life on Earth. I could not convince her that curiosity-driven exploration was at the heart of human civilization, starving or otherwise. Finally, the arguments ended inconclusively when I raised a rhetorical question, 'What was the level of poverty and deprivation in Italy in the days of Galileo Galilei?', I asked, feeling that would end the debate amicably. Neither

*This was the subject of the Foundation Day Lecture delivered at Inter-University Centre for Astronomy and Astrophysics, Pune, India, on 29 December 1994.

of us knew for sure, but she promptly shot back that it really did not matter, since Galileo's star gazing was not funded by the State.

Galileo – the star gazer

Her reply had me stumped, until just a few days later when I came across a review by A. C. Grayling of GALILEO: A LIFE, a new book by James Reston Jr. If any one man acted as a doorman to the modern world, Galileo Galilei has an excellent claim to the title. The publication of his latest biography is timely because Reston has hooked his tale firmly to events in the contemporary world: the flight of the spacecraft Galileo to Jupiter, still taking place as I speak to you, and the decision of the Vatican in 1992 to acknowledge its fault in ill-treating Galileo three-and-a half centuries ago by dragging him before the Inquisition, humiliating and imprisoning him.

Indeed, Galileo's story is a microcosm of the epic struggle between science, religion and society. Galileo was inquisitive, inventive and mathematically adept. He was fascinated by the view above him in the clear Italian night sky. He perfected the telescope, and terrified the Church by revealing more stars than had been guessed before, hitherto unseen satellites orbiting other planets, valleys and mountains on the surface of the moon.

Because Christian scriptures taught that the Earth sits immovably in the centre of the Universe, whose celestial spheres are driven around by angels, the Church could not tolerate this new cosmology.

By threats and intimidation, Pope Urban VIII forced Galileo to recant his espousal of the Copernican system. That the Church should come to its own recantation in 1992 speaks volumes for the conflict between faith and reason. Therefore, I cannot consider my friend's wife's question of whether astronomy research is really needed in a poor country like India unusual.

Galileo not only made discoveries of prime importance in astronomy and physics – especially in the laws of motion, thus breaking the stranglehold of Aristotelian ideas – he was also an inventive genius. He devised, amongst other things, pendulums for clocks, ways of improving telescopes and instruments for measuring pulse rates and temperatures. Despite disgrace by the Inquisition, his telescopic discoveries made him a star all over Europe.

While I have not been able to locate evidence of State support for his experimental pursuits. I am reliably informed that there were many poor people in Italy at the time Galileo gazed at the stars.

From star-gazing Galileo to the man behind the comet, Edmund Halley

Soon after the book on Galileo, I came across an excellent piece by Allan Chapman of Wadham College, Oxford, on a remarkable man.

Chapman avers that scientific research has always been expensive, but in the past, the real cost was not so much the hardware, as paying for the scientists' time. This is why so many discoveries between the 17th and the 19th centuries have been made by clergymen, semi-retired professionals and businessmen, and people of private means – individuals who were in command of their own time. But while the cash was not entirely certain, if one had the ability to wear many hats and cultivate friends across the whole spectrum of potential influence, then one might enjoy a career similar to that of Edmund Halley (1656–1742). This immediately brought to my mind some eminent Indians who fit parts of this description, like Ramanujam, C. V. Raman and Homi Bhabha, to name just three.

Edmund Halley's work was funded by, to begin with, family money. When that ran out, he worked as a clerk at the Royal Society, then took a job with the Royal mint, and later joined the Royal Navy. At the age of 48, he became a professor at Oxford and at 64 the Astronomer Royal. Edmund Halley was clearly capable of living with uncertainty.

Though primarily an astronomer, what is most impressive about Halley's approach to science is his awareness of how the great 'systems' of nature are interconnected. Geomagnetism was such a system. Halley published major papers in 1683 and 1692 in which he collected and analysed a growing body of data on the subject. He created the geomagnetic chart and then in 1716 he was the first to recognize the interconnection between the Earth's magnetic field and the aurora borealis.

Halley was a man of vast interests, ranging from pure science to a whole series of practical applications in marine engineering.

I imagine in modern parlance one would find comparable traits in the venture entrepreneurship of many famous American academics and Nobel Laureates. But where are the young Bhabhas and Ramans, I wonder.

Fred Hoyle – the astrobiologist

No address in an institute headed by Jayant Narlikar would be complete without reference to his Guru, Fred Hoyle, the astrobiologist.

Being somewhat of an amateur biologist myself, Hoyle's 'origin of life' hypothesis intrigues me. In his autobiography, *Home Is Where The Wind Blows*, Hoyle is sanguine about the chances of acceptance of his idea that life began in the vast expanses of space. 'Finding glycine is about 5% of the way to proving the idea', says Hoyle, 'It's the right way, but it's only 5%'.

The glycine discovery certainly bolsters Hoyle's thesis that the first organic matter rained down on Earth from space. According to Hoyle, it was such a comet which struck Earth about four billion years ago, depositing its cargo of primitive cells – the forerunners of all life today.

It is a rather controversial view, although the idea that organic material – the 'feedstock of life' – came from space is gaining wider acceptance. One is, however, faced with the moral and philosophical dilemma about the true origin of the living form. Hoyle acknowledges that the riddle will not be solved in his lifetime. However, he has been proved right before. In 1940 he had suggested that molecular hydrogen was widespread in space and was greeted with wide disbelief. He subsequently published his views in a science fiction book, *The Black Cloud*. Since the publication of the book, more than 100 molecules have been detected in space, including molecular hydrogen, which is now known to be the most abundant molecule in the Universe.

Marcus Chown (*New Scientist*, 10 September 1994) writes, 'Hoyle believes that, if a problem has an orthodox solution, the scientific community would already have found it, so he looks for the unorthodox solution'.

This unorthodox approach has proved Hoyle right on a number of predictions and wrong in just as many, such as the making of the sun or the explanation of binary stars.

But as the saying goes, 'If you have not made mistakes, you have really not tried'. I hope the adage applies to this Institute also.

I was pleased to learn that since 1988 Hoyle has developed the 'quasi-steady-state theory' jointly with Burbridge and Jayant Narlikar. The three of them believe that the creation tap opened in one part of the Universe 15 billion years ago, unleashing a flood of matter and causing the expansion of galaxies we observe all about us. Who knows they may be right!

Finally, I feel much comforted by Hoyle's view that 'a little bit of god operates in all of us. We are his observing instruments. He observes the Universe through us'. No matter where you are, whether in Cambridge or California or Pune, it all happened together.

Has science lost its way?

While I was warming up to the theme of science for curiosity's sake, I was crestfallen to read Bernard Levin's essay titled 'Has science lost its way?' (Even if I were to ignore Levin's levity, in the UK, observations on science such as his fall under the classification of 'Have you beaten your wife today?'.) Like it or not, some of this reflects contemporary lay thinking.

Bernard Levin's motto seems to be 'Beware of scientists claiming breakthroughs'. He then goes on to observe that 'If the boffins do have a fault, it is their conviction that any amount of money required for their work should be immediately provided'. In this essay, Levin chose the quarks as his centrepiece to criticize the nature of scientific enquiry and quotes a neat example of his odd but touching belief from a recent breakthrough in science. The last quark had been spotted (or rather not spotted. The thing is invisible). Arie Bodek from Chicago said that his discovery had saved scientists from an intellectual crisis 'since failure to discover the top quark would have shattered decades of research worth billions of pounds'. Levin asks, if the quark cannot even be seen, 'What is in it for us?'. The moot question is, what can discovery of quarks do for the common man? To Levin's queries, the only response he was able to elicit is that there are six quarks named UP, DOWN, CHARM, STRANGE, TOP and BOTTOM, and that 493 scientists were enlisted to find the last quark, going about the search 'smashing protons and antiprotons in a four-mile circular accelerator' and on top of that 'the two particles annihilate each other as they collide'.

Bernard Levin then moves on to compound his confusion by relating the discovery of a new planet 7000 trillion miles away. Hitherto 'in every case, the putative planets had either proved impossible to confirm, turned out to be something else, or shown to be a product of error'. Now, however, Wolszczan's team 'has bolstered its original findings with three more years of even more finely nuanced data designed to eliminate any explanation other than planets'. And this statement is backed by Kulkarni, a pulsar expert at the California Institute of Technology, who says, 'It should convince even die-hard sceptics that planets exist outside the solar system'.

Amongst other things, Levin concludes by noting that, whereas the common man may not very much begrudge the scientists the millions and millions of pounds needed to peep beyond the solar system 'where God resides!' while millions and millions may starve and suffer from malnourishment around the world, surely the tax-payers have a right to understand better where all these discoveries are leading.

Well, there we go! In quick succession, the wife of one of my best friends from India and the well-known columnist Bernard Levin, two persons from two totally different societies, asking very similar questions. Then interesting events started happening in July.

Shoemaker Levy 9

My interest perked up on reading the news that the comet Shoemaker Levy 9 was moving as a funeral procession of 21 fragments of ice and rock after its break up two years ago. Their eventual collision with Jupiter was being described by astronomers as a 'once in a millennium opportunity'. The subsequent pictures and descriptions of the collision were widely reported around the world by the media. I am told that it will take years before the explanation of the events leading to this collision are well understood. But the pictures and descriptions of the events started making sense to the common man as to why we stare at the night sky. This has been further encouraged by the fact that, unlike the Shoemaker couple who are professional astronomers, Levy is an amateur.

Suddenly Big Bang is back on the agenda and the question on every one's lips is, 'If it could happen to Jupiter, can it not happen to Earth?'.

Comets are celestial bodies, believed to be the relics of the birth of the solar system. A thousand or so of them have had their orbits well plotted. But for every comet which is confirmed to exist, there are thought to be at least ten others that have eluded detection. And billions more may reside in a halo beyond Pluto. Comets have collided with Earth before, and scientists insist that more collisions are probable, making it vital to overcome complacency about the threat to Earth from cosmic debris.

If a comet, streaming along at 50,000 miles per hour, were to crash into Earth in the wrong place at the wrong time – London, Bombay or New York at rush hour – it could cause a disaster of monstrous proportions. These thoughts were expressed in the editorials of the serious *London Times*. There is a school of serious astronomers, aptly known as 'catastrophists', which is convinced that within the celestial procession of comets lie the seeds of Armageddon. They attribute the death of the dinosaurs, 65 million years ago, to a comet which ploughed into the planet triggering either a nuclear-style winter or uncontrollable fires. The serious question is: If the comet could wipe out the mighty *Tyrannosaurus rex*, what chance do puny *Homo sapiens* have?

Thus, contemplating the impact of the 21 fragments of Shoemaker Levy 9 on collision with Jupiter in our lifetime has raised modern astronomy from the preoccupation of the specialists to a concern for all living and thinking mankind, starving or not.

Such an extraordinary astral event then starts stretching the mind and arouses the interest of the layman in astronomy, as indeed it did mine. I then began to think that although man has the technology needed to detect and track threatening celestial objects, there is yet no global chain of telescopes. And research has still to be aimed at defending the Earth from 'asteroid attack', including the possible redeploy-

ment of nuclear warheads to shatter incoming projectiles and the use of propulsion units to divert or steer them away. None of these, however, will protect us from every conceivable threat, nor can they whet our awe at the immensity of space. The 'black that remains beyond our blue' seems destined to remain a mystery to all but our telescopes.

The social relevance

No matter how awestruck I am, I cannot avoid relating all of this to developments in India. I hope I have provided a reasonable, layman's support to the need for the pursuit of the planets even in Pune. The statistical probability is that, next to China, India should have the largest number of curious people. This does not necessarily mean that we should have the second largest population of astronomers peeping through a chain of telescopes across the Indian subcontinent. However, in astronomy we have a history of interest as recorded in the Puranas, through the Middle Ages, and now this world-class centre in Pune. There is, thus, a tradition in mathematics and physics which links the ancient with the leading edge in India.

This, unfortunately, is not the case in most other areas of modern science and technology. Although we talk of modernizing and globalizing India, in lay terms what we really mean is a growth in production and consumption in our lifetime rather than a change in the fundamentals of looking and doing for a better future. I am, therefore, proud that India is considered to be a world player in astronomy and astrophysics, if not in any other sphere of science and technology.

Following our independence after over a thousand years of enslavement, Nehru, Bhabha, Bhatnagar, Meghnad Saha and many others inspired my generation to believe that science and technology held the key to traverse the path from backwardness to modernity and provide social justice for all. History will record that for the first three decades this promise at least seemed to begin to materialize. The role of science and technology in India achieving self-reliance was indeed significant. India thus achieved a critical mass as a democracy with a viable economy, although the problems of social inequity remained.

At a time when we are ready to integrate India's economic developments with the rest of the world, the same science and technology institutions which helped in achieving self-reliance may now turn out to be the major source of competitive disadvantage. Any attempt to revive them may be futile, as many of them may have outlived their utility. What is necessary is to take drastic steps to restructure and modernize the old and, in addition, create new institutions for the future.

Who should be concerned about this vital problem? The Government, Indian Industry, the non-Government Organization (NGOs), the media, the intellectuals, or whoever? Since 1990 even the interest and vibrancy in the science and technology community that one felt and saw in the 1980s seems to have dangerously waned. Unusual and dangerous priorities have overtaken the nation, such as disputes regarding places of worship, the revival of the caste conflict, the drive for instant gratification and enrichment, multinational baiting, the 'back to primitive roots movement', etc. There is not even lip service paid to the social and economic imperative to modernize our institutes of higher education and those institutions dedicated to advanced research in different areas of S&T. Every country other than India seems to be deeply engaged in addressing these vital issues. China is set to revamp its total research base, from one which had remained isolated and totally dependent on the State, towards one which is more autonomous, modern and globally relevant. There is a similar reassessment of the science base in the USA and Japan. In the UK, the 1993 White Paper on the need to choose areas of science in which to lead and its relevance to that country's global competitiveness was articulated. The key was that not every country could afford to be outstanding in every discipline of science. What a nation needs is a solid foundation in basic and higher education and then the ability to choose areas of science to excel in, by the combined efforts of the Government, Academia and the Industry.

As an Indian it frightens me today that, as we enter the most complex and competitive period in human history, we in India seem to adopt a policy of benign neglect of higher education and leading-edge S&T. Probably, the only other tragedy that this policy can be compared with is the disarray in the once powerful S&T culture of the former Soviet Union with its devastating consequences.

India does not have a choice. All of us must raise our voices against this benign neglect, in which lie the seeds of economic impoverishment and social disarray. Just talking about liberalization, economic development and poverty alleviation will not do. There are limits to foreign investment and export growth. Without overhauling our S&T base India faces a finite economic horizon.

I, therefore, disagree with my friend's wife and with people like Bernard Levin. Just because we are unable to comprehend science-speak or because many mediocre practitioners may have given science a poor image, it does not mean that there are better alternatives to achieving excellence in science. For there are none. More people will die of starvation and malnourishment without scientific advances and more nations will face decline and catastrophe without the pursuit of scientific knowledge. I am, therefore, thrilled that Narlikar and his dedicated colleagues have built this world-class facility in Pune. Could this be the faint glimmer of light at the end of the tunnel? We need a few more of these, and soon. I am encouraged by developments in massive parallel computing, also in Pune, advances in complex materials in the Institute of Science in Bangalore, the modernization of NCL and a few other such developments. They cost very little money. What they need is a few great minds. As an Indian, I am grateful that we have a fair number of excellent minds. Let us create the environment in which they can flourish to prepare India for the next century.

Jayant and I had the privilege of being members of Rajiv Gandhi's Science Advisory Council. In every meeting we had with him, we enjoyed inspirational debates on the choice of blue-sky priorities. True, even then, everyone was aware of India's day-to-day problems, but it was not a question of either/or. Such debates have now waned. I hope Narlikar and his dedicated group will help revive the debates, even beyond blue skies. I sometimes wonder, if only we could divert a fraction of the energy of our people away from breaking down places of worship or participating in caste riots, towards the pursuit of scientific enquiry, could we transform our nation and start realizing our potential?

I am now pleased about the brief encounter Jayant and I had in January 1994.

Ashok S. Ganguly works in the Research & Engineering Division, Unilever PLC, London, UK.

Scientific tradition and other traditions*

B. M. Udgaonkar

In the 'Project of History of Indian Science, Philosophy and Culture' (PHISPC), our concern has to be with the trio science–philosophy–culture, in interaction with one another. This is where the uniqueness of this project would lie. Unidimensional discussions of any one of the trio should have no place in the volumes that result, except where they raise important questions at the interface(s). And in that case, experts in two (or three) dimensions should have sessions together to sharpen the questions and, to the extent possible, arrive at (even tentative) answers to these. This has already been emphasized by Chattopadhyaya[1]. However, it bears repetition in view of the contents and presentation in some of the 'Occasional Papers' that have been brought out so far.

Indian civilization is about 4500–5000 years old (including the Indus Valley Civilization period; 8000 years old if one includes the pre-Harappan findings in Baluchistan). During this period, India has made many important contributions to science, technology, philosophy and culture. How did the developments in each of these areas influence one another? During this long period, what was the place of science in philosophy and in the civilization at large, at different epochs?

What role do the dominant scientific concepts play in the differential development of philosophy in different cultures? For example, Seal[2] observes that 'Hindu philosophy on its empirical side was dominated by concepts derived from physiology and philology, just as Greek philosophy was similarly dominated by geometrical concepts and methods', and adds that 'Comparative philosophy, then, in its criticism and estimate of the Hindu thought, must take note of the empirical basis on which the speculative superstructure was based'. This assertion would merit a detailed discussion. Is the assertion true? Or is it an oversimplification with regard to both Hindu Philosophy and Greek Philosophy?

Established science at a given time influences philosophy and *vice versa*, though radically new developments do so usually with some time lag. How does one see these influences at work, in general in the Indian context? What were the positive and negative influences at different epochs? Chronology becomes important in this context. There are, however, serious chronological uncertainties in Indian history.

In the case of science, one tends to compare the Indian situation with the developments in Europe over the last few hundred years, is overawed, and it is not uncommon to hear loaded counterfactual questions like 'Why did India have no science? Is it because of its tradition?'. In asking such questions, the foreigner and, following him, many Indians, forget that science based on observation and empirical methods is to be found in the practice of the ancients in India, and that science is as much a part of our heritage as the greatly extolled mystical tradition[3–5]. One has legitimately to take a longer time scale for any comparison, and counter the ethnocentric prejudices with facts.

The time scale of several thousand years also means that concepts may have changed with time. This has to be constantly kept in view. For the impact of any given concept, e.g. *Māyā*, one has to ask the meaning attached to it during different epochs.

Indian contributions to science and technology from the earliest times have begun to be documented[3–5], though there is no comprehensive work yet comparable to that of Needham and coworkers on China. It is, however, by now recognized that India's contributions to science and technology over the centuries are quite significant. This is, however, not the subject of our discussion. Rather, we will try to survey the reasons which have often been adduced as to why, in spite of a strong early base in science and technology, India failed to build on it during the last 500 years. Why did this happen?

Why did India lag behind in recent centuries?

The question often raised is: If Indians had the questioning attitude and the tradition of experimental and mathematical investigations at one time, and if they made significant contributions to developments in science and technology, especially up to about 1200 AD, and maintained their superiority in certain technologies, e.g. textiles, metallurgy, architecture, ship building, etc., right up to the 17th or 18th century[6–8], why did they fail to build further on this base? Why was it left to Europe to develop modern science? Were there some factors in our traditions which came in the way?

In history, such questions as to why something did not happen are difficult to answer. They are even treated as nonquestions by some historians. There are several questions of this kind that one could ask about Europe: e.g. why is it that none of the religions of today started in Europe? Why did they all start in Asia? Why did the early wave of science and philosophy in Europe not start in mainland Europe? Why did it start in an insignificant southeastern corner of Europe and in adjoining Asia (called Asia *minor*)? Why did the Europeans not discover zero? And why was Japan *relatively late* in joining the march of civilizations? And so on. One has no simple and straightforward answers to such questions.

China and the Arab world were also unable to build on the early head-start. Maybe different sociopolitical and historical circumstances were responsible in each case. These need to be studied in an unprejudiced manner, using such meagre data as are available and reconstructing where there are gaps (and there *are* many gaps), with a more open mind than has been customary. Many times hypotheses were made by Western scholars in the colonial period, and these have been echoed by Indian scholars even in the post-Independence era. A kind of colonial thinking has tended to persist, even if unconsciously, and so these hypotheses have to be looked at afresh.

*This article was originally prepared for the Project of History of Indian Science Philosophy and Culture of the Indian Council of Philosophical Research and was brought out as Occasional Paper 24 of the Project.

While listing some of the ideological or attitudinal factors which have been held responsible for India's inability to build on its early base, and making some comments on them, we would like to emphasize at the start that they do not strike us as having the status of anything more than speculations or prejudices, given the importance of the question being discussed. Much more detailed work is needed before any of the prevalent myths in this domain could attain the status of causal relationships *vis-à-vis* development of science in India. Wherever any of the factors have their counterparts in other civilizations, especially the European civilization, a comparative study would be called for.

It is to be hoped that the relevant sections on philosophy and culture in the volumes that will come out of PHISPC will deal with these questions in depth.

The supposed other-worldliness of Indian culture

It is alleged that early Indian culture was other-worldly, that it perceived the world as *Māyā* or illusion, and that the conceptual world-worthlessness led to a lack of interest among Indians in any worldly pursuits. Indians, it is said, were only interested in the liberation of the soul as a goal, and not in studying the external world.

It may be argued that a distortion of the concept of *Māyā* is involved in such an argument. Even if this is so, it would be useful to know the extent to which the distorted/corrupted interpretation of *Māyā* affected a young intellectual's choice of a field of study during different epochs of our long history. Were the brightest enquiring minds turned away from the study of worldly phenomena?

Related to the interest in other-worldly entities was the distinction made between what was called *parā vidyā* and *aparā vidyā*, the higher kind of knowledge and the lower kind of knowledge, and the influence such distinction would have had on the perception of what was really worth studying and worth respecting.

In the *Mundaka Upanisad*, we find the question put by an earnest student to a great teacher: 'What is that reality by knowing which we can know all that there is in this manifested universe?'. The teacher replies: 'Two are the *vidyās* or sciences to be acquired by man, so say the knowers of *Brahman*. One is called *parā vidyā*, higher science or knowledge', the other is called *aparā vidyā*, ordinary science or knowledge'[9]. The knowledge/search for the knowledge of the soul was considered the higher knowledge. Since what was considered *really worth knowing* was to be approached by turning the light inwards, this may have come in the way of the study of the external world. The best minds may have turned towards the exploration of the inner world – toward spiritualism and mysticism – which was placed on a higher pedestal in the name of *parā vidyā*.

Then there was 'a powerful current'[10] in Indian culture that 'the truths of the physical and supra-physical realities can be grasped, known and possessed by us through faculties which lie above the ranges of physical senses and rational intelligence'[10] and that the knowledge obtained by development of those higher faculties, by yogic means, through meditation and intuition, is superior to that obtained by one's senses and reason[11]. The gods have sometimes been described as *pratyaksa-dvisah*, i.e. as hating something that is acquired by the senses. How powerful was this current *in space and time*?

It has also been stated that the fact that renunciation was an accepted and respectable way of life fed these trends and came in the way of development of science and technology.

The *Karma* ideology has also been adduced as a cause – the idea of previous births and their consequences in the current life, and the resultant fatalism.

The influence of the *Bhakti-Marga*, which spread in the country through the emergence of a series of saint-poets after the eighth century in different emergent languages and their compositions, which became very popular, has also been mentioned.

While Indian culture has had such negative tendencies, it is not clear how widespread was their effect in space and time, in a large country and a stratified society whose intellectual history spanned three to four thousand years – especially as India has many important scientific discoveries to its credit over the centuries. This is a matter that needs to be looked into carefully from the point of view of possible impact on the development of science. Vivekananda, one of the greatest of the modern exponents of *Yoga* and the *Vedānta*, has, for example, laid repeated stress on the experimental character of *Yoga* and on basing it on reason[12].

Referring to the flourishing trade between India and Rome during the period 200 BC to 300 AD, Thapar[13] mentions Pliny's complaint that the Indian trade was a serious drain on the national income of Rome. The Frenchman Bernier, who travelled in India more than 1500 years later (1656–1668), says: 'It should not escape notice that gold and silver, after circulating in any other quarter of the globe, came at last to be absorbed in Hindustan'[14]. These are not observations supporting the other-worldliness of Indians over the centuries.

It is interesting to see what Vivekananda has to say about *Māyā*, especially in relation to scientific pursuits. Vivekananda refers to *Māyā* as 'one of the pillars upon which the *Vēdānta* rests'[15]. He, however, warns us that the word *Māyā* is used incorrectly to denote 'illusion or delusion or some such thing'. Having said this, he proceeds to give a number of examples to illustrate what *Māyā* is, a couple of which are quite intriguing:

> 'A man of science rises, he is thirsting after knowledge. No sacrifice is too great, no struggle too hopeless for him. He moves onward discovering secret after secret of nature, . . . and what for? . . . Why should we give him glory? Why should he acquire fame? Does not nature do infinitely more than any human being can do? . . . Nature can hurl a thunderbolt of any magnitude to any distance. If a man can do one small part as much, we praise him and send him to the skies. Why? Why should we praise him for imitating nature, imitating death, imitating dullness, imitating insentience? . . . Yet we are all struggling after that. And this is *Māyā*'[16]. '. . . so with our intellect. In our desire to solve the mysteries of the universe, we cannot stop our questioning, we feel we must know and cannot believe that no knowledge is to be gained. A few steps, and there arises the wall of beginningless and endless time which we cannot surmount. A few steps, and there appears a wall of boundless space which cannot be surmounted, and the whole is irrevocably bound in by the walls of cause and effect. We cannot go beyond them. Yet we struggle and still have to struggle. And this is *Māyā*'[17].

'. . . Is there no hope then?' He continues, 'True it is that we are all slaves of *Māyā*, and live in *Māyā*. Is there no way out? No hope? . . . on the other side, therefore, is the bold assertion that this is all nonsense, that this is *Māyā* . . .'[18].

At another place, Vivekananda says,

'. . . the minds of the people from whom the *Vedas* came were intent upon following principles, discovering principles. They had no time to work upon details or to wait for them, they wanted to go deep into the heart of things. Something beyond was calling them, as it were, and they could not wait. Scattered through the *Upanisads*, we find that the details of subjects which we now call modern sciences are often very erroneous, but at the same time their principles are correct . . .'[19].

We have chosen to quote at length from Vivekananda since he represents in a sense a link between ancient tradition (rather, the *Advaita* tradition) and modernity, and an important figure in the Indian renaissance towards the end of the last century. Is he also undervaluing the importance of scientific pursuits as we understand them? Do such views reflect the thinking about science in one important school of thought over the centuries? If so, could they have been partly responsible for nondevelopment of modern science in India? In science, what the Swamiji called 'details' are as important as 'principles'; 'details' are, in fact, an important path to 'principles' and have often led to the overthrow of earlier 'principles'. What does one mean by saying that details were erroneous while principles were correct? In science, no general principle is frozen as unassailable knowledge for all time. The strength of the scientific method is precisely in the openness to new principles in the light of new 'details' as they unfold themselves.

Thapar[20] has noted that 'Indians in the pre-eighteenth century never claimed that they were more spiritual than other people, or that the Indian way of life was concerned solely with things spiritual. The ideal of the earlier texts that the best life on earth is a balance between *dharma*, *artha* and *kāma* shows a healthy unconcern for any obsession with either the spiritual or the material'[20].

Works like the *Kautiliya Arthasāstra* show the detailed interest taken by ancient Indian scholars in worldly matters of government (which was not dominated by priesthood) in all its aspects.

Nehru has remarked: 'Probably the Semitic culture, as exemplified in many religions that emerged from it, and certainly Christianity, was far more otherworldly'. 'Indian culture taken as a whole', he adds, 'never emphasized the negation of life, though some of its philosophies did so; it seems to have done so much less than Christianity'[21]. Nehru points out that 'in India, we find during every period when her civilization bloomed, an intense joy of life and nature, a pleasure in the act of living, the development of art and music and literature and song and dancing and painting and the theatre, and even a highly sophisticated inquiry into the sex relation. It is inconceivable that a culture or view of life based on otherworldliness or world-worthlessness could have produced all these manifestations of vigorous and varied life. Indeed, it should be obvious that any culture that was basically other-worldly could not have carried on for thousands of years. The confusion seems to have arisen from the fact that Indian thought was always laying stress on the ultimate purpose of life. It could never forget the transcendental element in its make-up . . . It taught detachment in life and action, not abstention from them'[21].

Thapar[22] has discussed the origin of the stereotype. 'The theory of the instinctive unconcern of Indians for worldly things is found particularly useful in minimizing such obvious factors as colonialism in economic underdevelopment. The explanation of Indian economic backwardness does not lie in simplistic generalizations on Hindu culture but demands a detailed investigation into the nature of pre-colonial and colonial society in India'[22].

Alvarez[23] has observed: 'There is still no evidence to date that one line of thought was so dominant that it had become "orthodox": there was no single established view that set itself up against and above a number of other supposed heresies. The hypothesis that Hindu philosophy (wrongly identified wholly with the idealistic school) proved disastrous for India's technical capacity or economic activity should be relegated to the garbage heap; so too, the fashionable cliché that India spent too much of its energy in the pursuit of metaphysical speculations . . . .'

Suppression of the scientific spirit for political reasons

Chattopadhyaya[24] has argued that there was a systematic suppression of materialists – e.g. the *Cārvāks* – and of materialistic ideologies in ancient India. He has written extensively on this theme, and he, and before him Fillozat, has made a case study of medicine in ancient India.

Chattopadhyaya points out that already in the ancient period, some 2500 years ago, Indian medicine had taken the momentous leap from magico-religious therapeutics to rational therapeutics (from *daiva-vyapāsraya-bhesaja* to *yukti-vyapāsraya-bhesaja*). This was a very risky step, he says, the risk involved being political. 'To question even by implication – mysticism, ritualism and religion – necessitates also rejection of the very way of life all these tend to justify. It amounts to questioning the very norm on which a hierarchical society wants to thrive.' Further, the early medical men were looking for material, natural causes of diseases. Chattopadhyaya argues[25] that the view of the laws inherent in nature – technically called *svabhāva* – is essential for *Ayurveda*. Thus, the fundamental postulates of ancient Indian medicine are:

(i) everything in nature takes place according to laws inherent in nature;
(ii) though immutable, these laws are nevertheless knowable;
(iii) the knowledge of these laws brings power over nature, which medically means ensuring a long and healthy life.

This emphasis on *svabhāva* rejects *adrstavāda* or *karmavāda* or any supernaturalism. Chattopadhyaya[26] argues that this natural cause and effect approach to human ailments and their treatment was considered subversive by the priests, and the Indian law-givers were 'obliged to denounce it as abject heresy'. This led to the downgrading of the practitioners of medicine in the social hierarchy, by the law-givers, and also to interpolations of theological/philosophical discussions in the *Caraka-samhitā*, which are inconsistent with its rational spirit.

The conflict between science and the counter-ideology was also present in

Europe in the middle ages. There was the inquisition, the burning at the stake of nonconformist thinkers like Giordano Bruno, the trial and humiliation of Galileo, and the indexing of books. How does one compare the conflict between science and the counter-ideology in India with that in Europe? Why was it that the counter-ideology could prevail in India, whereas Europe could get over its influence?

Is the argument of Chattopadhyaya regarding suppression of materialism in relation to Indian medicine overdrawn? It would be useful to have a fresh look at it. Medicine did thrive in India, did make advances[27] and even spread outside India down to the eighth century. Indian doctors were imported by the Abbasid Khalifas to supervise their own hospitals in the 8th century AD and Sanskrit medical texts were translated into Arabic[28].

A Spanish Muslim scholar, quoted by Chattopadhyaya himself, says in 1080 AD that Indian medicine was the best in the world.

Further, when Francis Buchanan carried out a survey of the state of medicine and surgery in 1807, under orders from the Court of Directors of the East India Company, he observed in relation to Bihar: '*Medicine is taught by several of the Pandits, some of whom also, though they are grammarians, practice the art . . . Besides the Professors of Medicine, about 700 families of Brahmans, almost all of Sakadwip, practice that art and are the only Hindu physicians who possess anything like science . . .*'[29] (emphasis added).

Conflict between science and religion

It is not unusual to find it claimed that unlike in Europe, there was no conflict between science and religion in India[30, 31], because there was no hostility to science or to new ideas in philosophy, on the part of religion; that even atheists were not persecuted in India. This was true in early times, when there was full intellectual freedom, a beautiful example of openness being the *Nāsadāya sūkta* in the *Rigveda*. There were as many as sixty-three systems of philosophy in the days of the Buddha, and very few of them cared to rely on Vedic authority for their hypotheses or their conclusions. Within the fold of the orthodoxy itself there were the *Sānkhya*, *Mimāmsa* and *Nyāya* systems, which had hardly any appropriate place for the divine Creator in them. Buddhism and Jainism were not summarily dismissed as atheistic. But certain works came to be canonized some time around 600 BC, and an almost equal reverence came to be paid to the *Smrtis* and *Puranas* in the course of time. Theories began to be accepted or rejected according as they were in conformity with or opposed to statements of the sacred books[32]. Already by the time of Sankara, the pressure was quite strong. Intellectual giants like Sankara and Rāmānuja had to spend a disproportionate amount of time and energy to prove that their systems of philosophy were in conformity with and the natural outcomes of the *Upanisadic* hypotheses. Independent development of philosophies was affected. Instead, one only had commentaries on the revealed literature[32].

The separation of philosophy from theology, and of science from philosophy, also did not take place. This separation would seem to have been an important step in European development. It enabled science to go ahead when theology and metaphysics stagnated.

Under such circumstances, there was not much scope left for research and originality in those matters where opinions were expressed in the sacred books, which now included *Smrtis* and *Purānas*. A glaring example is that of the mythological stories about *Rāhu* and *Ketu* temporarily overpowering the moon or the sun and thereby causing eclipses, which got canonized by inclusion in the *Purānas*. Aryabhata, (*ca.* 500 AD), Varahamihira and Brahmagupta (*ca.* 600 AD) knew the scientific explanation of eclipses but were powerless to explode the myths. In fact, Brahmagupta went to the extent of condemning Aryabhata, Varahamihira, Srisena and Visnucandra for expounding the unorthodox but scientific theory of eclipses. Alberuni has suggested that Brahmagupta made the compromise because a calamitous fate like that of Socrates had befallen him[33].

Was this also the reason why Aryabhata's suggestion that the earth revolves around its axis was not followed up by later astronomers? Or, for the fact, that the idea of impetus could not develop into inertia, force, etc., – perhaps the most important developments in Europe that launched the scientific revolution?

Incidentally, it will be useful to have more light thrown on the process of canonization of scriptures, including the *Smrtis* and the *Purānas*, which made it impossible for even outstanding intellectuals like Brahmagupta to counter stories like those of *Rāhu*, *Ketu* and the eclipses, and also to document other instances of this kind. Is the view that there was no conflict between science and religion/spirituality a modern view, or does it go back to ancient times?

Swami Ranganathananda[34] quotes from Sankarāchārya's commentary on the *Brhadāranyaka Upanisad*: 'Nor are the *Srtis* (the *Vedas*) supposed to have authority in matters which are contradicted by other means of knowledge, for instance, if they said, 'fire is cold and wets things'. Was such thinking widely accepted by scholars or people at large? During which epochs?

Possibly connected with this concept of knowledge as captured and frozen in the scriptures is the picture of a traditional '*Brahmin*' scholar today as a repository of knowledge in the books – rather than a free-wheeling creative intellectual, applying his knowledge to the exploration of new phenomena or providing improved explanations of the phenomena already known. When did the tradition of questioning as in the *Upanisads*, *Nyāya-Vaisesika*, and other early texts lose its vigour and a static view of the learning of the learned emerge?

The belief that all knowledge is in the Vedas

Vivekananda refers to the belief prevalent in India that all that is called knowledge is in the *Vedas*[35].

It is not uncommon to find it claimed even today that the *Vedas* are the storehouse of all knowledge – *spiritual and secular*. For example, Jagadguru Swami Shri Bharati Krishna Maharaj has said:

'The very word *Veda* has this derivational meaning, i.e. the fountainhead and illimitable storehouse of all knowledge. This derivation, in effect, means, connotes and *implies that the Vedas should contain within themselves all the knowledge needed by mankind relating not only to the so-called*

spiritual (or other-worldly) matters but also to those usually described as purely secular, temporal or worldly, and also to the means required by humanity as such for the achievement of all-round, complete and perfect success in all conceivable directions, and that there can be no adjectival or restrictive epithet calculated (or tending) to limit that knowledge down in any sphere, any direction or any respect whatsoever.

'In other words, it connotes and implies that our ancient Indian Vedic lore should be all-round, complete and perfect and be able to throw the fullest necessary light on all matters which any inspiring seeker after knowledge can possibly seek to be enlightened on.'[36] (emphasis added)

One should note that this statement of the Jagadguru is quoted by a former President of the Association of Indian Universities in his Foreword to the book *Science and the Vedas*.

It will be useful to know how old this kind of belief is in our cultural/philosophical history. When and how did it get ascendancy? Such a belief, if widely held, could lead to stagnation or even decline in science and could, therefore, be an important factor inhibiting the growth of modern science in India. It could also have inhibited the healthy development of philosophy.

Tendency to accommodate conflicting opposites

Indian tendency to accommodate conflicting opposites has been mentioned as one of the causes. The faith of some of our modern scientists in miracle-making godmen is cited as a present-day example.

Alberuni, the scholar–traveller who visited India around 1000 AD was very critical of the Hindus on this score: '. . . you mostly find that even the so-called scientific theorems of the Hindus are in a state of utter confusion, devoid of any logical order, and in the last instance always mixed up with silly notions of the crowd, e.g. immense numbers, enormous spaces of time, and all kinds of religious dogmas, which the vulgar belief does not admit of being called into question. Therefore, it is a prevailing practice among the Hindus *jurare in verba magistri*; and I can only compare their mathematical and astronomical literature, as far as I know it, to a mixture of pearl shells and sour dates, or of pearls and dung, or of costly crystals and common pebbles. Both kinds of things are equal in their eyes, since they cannot raise themselves to the methods of a strictly scientific deduction . . . '[37]

These are harsh words, possibly coloured to some extent by the arrogance of a person accompanying conquering Mahmud, but they should make us look introspectively at the cultural and philosophical milieu of that period.

Varāhamihira wrote in *Brahatsamhita* that the gems could have originated either from the bones of gods and demons, or on account of natural metamorphosis of rocks. The possibilities were given equal emphasis[38]. Biswas[38] has given more revolting examples from *Rasa–Ratna–Samuccaya*, a 13th century text.

Kosambi[39] has observed: 'The "logic" advanced by the *Brahmins* took good care to avoid all reality. The end result is seen in the philosophy of the great Sankara (800 AD), who threw out the proposition that "a thing is either A or non-A", and viewed the universe as divided into metaphysical categories upon several planes. The highest plane was, of course, of speculation about and unity with eternal principles. Material reality did not exist. The philosopher was thus excused if he joined the common herd on the plane of ritual observation . . . '

An oft-quoted example of this tendency as far as science is concerned is that Brahmagupta wrote the popular myth about the cause of eclipses (*Rāhu*, *Ketu* and all that) along with his calculation in terms of the correct astronomical explanation.

It is interesting to see what Saha[40] has said in this regard: '. . . in India, the votaries of the astronomical science apparently found it difficult to go against the scriptures. The Greek savants, with characteristic boldness and freedom of thought, had pooh-poohed the Homeric and Hesiodic cosmogony, they made light of the Olympic Gods. But the Indian savant never showed equal boldness. On the other hand, being accustomed to easy-going pantheistic tendencies, he was always ready to compromise and be accommodating in his views . . . never courageous enough to propose a bolder theory of the universe in opposition to current ideas. Aryabhata of Kusumpur (Patliputra) (born in 476 AD) thought that the earth, by turning round its axis, caused day and night, but his successors did not seem to be impressed with his ideas. It is, however, clear that they were keenly alive to the stupidity of public beliefs or utter inadequacy of the *śāstric* lore. "It is said", says Bhāskaracharya, "that the earth rests on the hood of a huge snake, which when it feels uneasy gives a shake and causes earthquakes. Well, the snake must have something to rest upon, let it be the tortoise, but this also must have something else to rest upon. So we have to assume the hypothesis of an endless string of the support and supporters. A better explanation would be that the earth has no support, i.e. is suspended in space". But the next sentence, he is careful to say, "but since these things are mentioned in the *Sastras*, there must be some truth in them"'.

Lest we are too harsh on Brahmagupta or Bhaskaracharya, we may note what Gould[41] has to say about Newton and Whiston, his successor as Lucasian Professor at Cambridge.

'The Newton of our Pantheon is a sanitized and modern version of the man himself.' He greatly admired the book *New Theory* by William Whiston (1696), to such an extent that Whiston ended up as Newton's handpicked successor as Lucasian Professor of Mathematics at Cambridge. The full title of Whiston's treatise gives an idea of its contents. Whiston called his treatise *A New Theory of the Earth from its Origin to the Consummation of all Things, Wherein the Creation of the World in Six Days, the Universal Deluge, and the General Conflagration, as laid down in the Holy Scriptures, are shown to be perfectly agreeable to Reason and Philosophy.*

In trying to establish a consistency between the two great sources of truth as defined by his countrymen – the infallibility of the Scriptures, and the mathematical beauty of the cosmos, so recently recreated by Newton – Whiston implicated comets as prime movers.

'Whiston has descended through history', remarks Gould[41], 'as the worst example of religious superstition viewed as an impediment to science'. '. . . We dismiss Whiston because he violated ideals of science as we now define the term. But, in Whiston's time, science did not exist as a separate domain of inquiry; the word itself had not been coined. No matter how we may view such an enterprise today, Whiston's mixture of natural events and scriptural traditions defined a primary domain at

the forefront of scholarship in his time . . . He did not view his effort as a work of science, but as a treatise in an important contemporary tradition for using all domains of knowledge – revelations of the Scriptures, history of ancient chronicles, and knowledge of nature's laws – to reconstruct the story of human life on our planet. The *New Theory* contains – and by Whiston's explicit design – far more material on theological principles and biblical exegesis than on anything that would now pass muster as science.'

The interesting thing in the context of our discussion is the fact that Whiston's work was highly thought of by no less a person than Newton.

It is also well known that at the same time that Newton was working on the *Principia*, he was also spending a substantial fraction of his time on investigations in alchemy and theology. On the other hand, he did not publish anything on either of these subjects.

Complacency developed during the period when the Indians had attained a high level of civilization

Another line of reasoning puts the blame on the complacency that the Indians had developed over a period of time: they began to think that they had attained the highest knowledge that humans were capable of and they progressively lost the questioning attitude and openness to knowledge from other sources (*ā no bhadrāh kratavo yantu visvatah*). In this context one often quotes Alberuni, who says the following about the attitude of Hindus of his time:

'They are haughty, foolish, vain, stolid and self-conceited. According to their belief, there is no other country on earth but theirs, no other race of man but theirs, and no created beings besides them have any knowledge or science whatsoever. Their haughtiness is such that, if you tell them of any science or scholar in Khurasan or Persis, they will think you to be both an ignoramus and a liar. *If they travelled and mixed with other nations, they would soon change their mind, for their ancestors were not as narrow-minded as the present generation is.*'[42] (emphasis added).

Gargi Samhita[43] says: 'The yavanas (i.e. the Greeks) are indeed barbarians, but astronomy originated in them and for this they must be venerated as Gods.'

Aryabhata and Varāhamihira also did not have the attitude described by Alberuni, though one probably sees the beginning of such an arrogant and exclusive attitude in *Varahamihir* when he says: 'The Greeks, *though impure*, must be honoured, since they were trained in sciences, and therein excelled others. *What then are we to say of a Brahman if he combines with his purity the height of science*?'[44] (emphasis added).

When did the vain, self-conceited attitude start dominating? How did it continue in spite of the humiliating defeats that the Hindu society had to accept from successive invaders?

The complacency or intellectual lethargy that had developed continued even after the Moguls came to power. Jawaharlal Nehru refers to the curious fact that Akbar did not take any interest in building sea power, though Vasco de Gama had reached Calicut, via the Cape, in 1498, and established Portuguese sea power in the Indian Ocean. What is more, this lack of interest continued even after the Portuguese started extracting tolls from traders and from pilgrims going to Mecca. He or the 'jewels' in his court also took no interest in printing[45], though the Jesuits presented him with a printed Bible. The Mogul army and the armies of other states in India depended on foreign experts for their artilleries. Why did Akbar or anyone else not send his own men abroad for training, or interest himself in the improvement of the artillery by encouraging research work? Why did they not take interest in developing Indian clocks, though imported clocks were very popular with the Mogul nobility?

Over the centuries, during the Gupta period and later, India imported horses from Arabia, Iran and Bactria. For some strange reason, India never took to the breeding of horses and training the veterinaries. Mentioning this, Thapar[46] remarks: 'The fact that India never bred sufficient horses of quality, the best blood having always to be imported, was to have disastrous consequences on the cavalry arm of Indian armies, eventually making the cavalry ineffective, especially in comparison with Central Asian hordes.'

Rigidity of the caste system

A factor that needs some discussion is the growing rigidity of the caste system in India, which led to the separation of the head from the hand[47]: Theoretical and philosophical studies (including the speculative aspects of science) were the prerogative of the *Brahmins*, whereas the practical arts and crafts were relegated to the other castes. These lower castes, moreover, did not have the benefit of formal education. This prevented the coordination between science and crafts, and theory and experimentation/experience. Also, the accumulated theoretical knowledge was accessible to *Brahmins* in Sanskrit while the common technicians, who knew only one of the Prakrits, had no access to it. It would be useful to compare and contrast with a similar problem in medieval Europe, where the accumulated theoretical knowledge was the prerogative of the Latin-knowing clergy and aristocracy and not accessible to common artisans. Also, when did the caste system become rigid from the point of view of separation of the head from hand? Altekar observes that after 800 AD, primary education became restricted to the higher strata of society; the vast majority of workmen and artisans became illiterate by this time and knew only the traditional processes of their profession[48].

The ban on foreign travel

Foreign travel seems to have got banned around the 8th century[49]. This is usually attributed to the increasing rigidity of the caste system, and the ideas of purity and impurity, especially in relation to mixing with foreigners and observing food taboos. Vivekananda in one discussion attributes the ban to a desire to prevent the Hindus from mixing with the surrounding Buddhistic nations. He says: 'The one great cause of the downfall and degeneration of India was the building of a wall of custom – whose foundation was the hatred of others – around the nation, and the real aim of which in ancient times was to prevent the Hindus from coming into contact with the surrounding Buddhistic nations.'[51]

Whatever be the cause, banning of foreign travel could not but have had a very adverse impact on the exposure to fresh ideas and new techniques, so essential for growth of science. Sharma[52] has discussed the possibility that Raja Jai Singh may have received wrong advice from his foreign consultants, the Jesuits, with regard to the state-of-the-

art in astronomy in Europe. Though their delegation visited Europe on his behalf, the Jesuits, because of their own theological beliefs and prejudices, may not have presented the Copernican revolution to Jai Singh in its true perspective. The European books which Jai Singh got translated into Sanskrit included the already obsolete *Almagest* of Ptolemy and not *The Revolution of the Heavenly Spheres* of Copernicus or *The Harmonies of the World* of Kepler or *Dialogues Concerning Two New Sciences* of Galileo or *The Principia* of Newton, all of which had been in existence for quite some time. Jai Singh also does not seem to have benefited from the developments in telescopes taking place in Europe, in planning his observatories. 'Unfortunately', says Sharma, 'The Raja seemed to have had no alternative but to send a team of foreigners on his fact-finding mission in Europe as no high-born Hindu of his days would dare '*cross the ocean*' and thereby risk 'losing his caste'[52]. This unfortunate predicament of the Raja need not diminish our admiration for his vision and his contributions to astronomy.

A handicap of the oral tradition?

The Indian tradition is said to have been largely an oral tradition, from the earliest times when the *Vedas* were not written but passed on by recitation from the *Guru* to the disciple, with explanations in the course of the transfer. Later when writing was developed (*ca.* 400 BC), the style was usually aphoristic, so that the intermediary of a *Guru* was needed for an understanding of the meaning of the esoteric texts. While commentaries helped to some extent, they often did not throw light on the rationale of the problem tackled or provide an insight into the mental working of the scientist, whose results were given cryptically in a *Sūtra*. Added to this was the secretive aspect of the tradition, which again, meant that if the symbolic language with secret meaning, or recipé, or special formula, was not transferred by a *Guru* to his (favourite) *Śisya*, that piece of knowledge disappeared[53].

Effect of invasions?

Successive invasions meant not only devastating destabilization of the functioning of the society, and loss of prosperity, it also meant loss of centres of learning, including their libraries. Alberuni[42] describes the effect of Sultan Mahmud's invasions: '. . . Mahmud utterly ruined the prosperity of the country, and performed there wonderful exploits, by which the Hindus became like atoms of dust, scattered in all directions, and like a tale of old in the mouth of people . . . This is the reason why Hindu sciences have retired far away from those parts of the country conquered by us, and have fled to places which our hand cannot yet reach . . . '.

India had at one time flourishing universities at Taksaśila, Vikramaśila, Valabhi, Nālandā, etc. Within a couple of hundred years of the above account by Alberuni, the 700–800 years old University of Nālandā, to which scholars came from various parts of the country and from abroad, was destroyed by Bakhtiyar Khilji. Bakhtiyar Khilji also destroyed the famous University of Vikramasila. These were the last of the great Indian universities to disappear. No great universities came up in the centuries that followed, either under the Afghans and the Moguls in the North, or under the Vijayanagar and other kingdoms of the South.

One may say that one had the *Gurukul* system. But such a *gharānā* system had its weak as well as strong points. It could not be a substitute for universities.

It would not be an accident that the bright period for Indian science and philosophy was also the period in which some of these universities flourished and attracted scholars from far-off places. One notes in this context the role played by the universities of Cordova, Cracow, Tübingen, Paris, Oxford, Bologna and Padova in the revival of learning (science in particular) in Europe. Some of the great architects of the scientific revolution in Europe had been at Padova at important periods in their career – Copernicus, Galileo, Harvey and Vesalius, to mention a few.

Even the great Akbar does not seem to have applied his mind to the setting up of universities. Why?

Just around the time when India's great universities were disappearing, new universities were coming up in Europe[54]. This was followed by the setting up of Academies/Royal Societies, which also were to play an important role in the intellectual life of Europe.

The effect of centuries of unsettled conditions that prevailed before a multi-religious composite culture could emerge needs to be analysed dispassionately without allowing either Hindu or Muslim chauvinism to distort the view of the happenings.

The British had stepped in before India could find its feet again.

Influence of Buddhism?

Going back to an earlier period, what were the positive and negative impacts of Buddhism on the development of science in India? The Buddha himself stressed the importance of the spirit of enquiry:

'Believe nothing
Merely because you have been told it,
Or because it is traditional,
Or because you yourself have imagined it.
Do not believe what your teacher tells you,
Merely out of respect for the teacher.
But whatever, after due examination and analysis,
You find to be conducive to the good,
The benefit,
The welfare of all beings,
That doctrine believe and cling to,
And take it as your guide.'

It is interesting that he said this around the time that some of the Hindu scriptures were getting canonized. Can one trace the healthy impact of this on science?

Later, things changed. As Chattopadhyaya points out in the course of his discussion of the vicissitudes of *Ayurveda*, while the concept of causality is absolutely crucial for *Ayurveda*, Nāgārjuna, the founder/exponent of the *Mādhyamaka* school of philosophy, popularly known as *Śūnyavada*, denied causality and condemned experience and reason as sources of right knowledge. What impact did this have on science?

It is curious that the decline of Indian science seems to have started around the time or in the centuries following the victory of *Ādi Śankara* over the existing Buddhistic doctrines and other materialistic and nonmaterialistic schools of Indian philosophy in the 8th century. Did this victory imply the reestablishment of spirit over matter, lead-

ing to a down-grading of creative science[55]?

Did the *Prāmānyavāda*, which followed in the succeeding centuries, have an adverse effect?

One hopes that an objective discussion of the positive and negative impacts will be forthcoming[56].

Too big a load from the past?

Was the continuity in Indian civilization a handicap? Europe lost its Graeco-Roman knowledge and tradition in the dark ages, and then recovered these a thousand years later through the Arabs, along with the knowledge which the Arabs brought from India. When this happened, the Europeans had a chance to have a fresh critical look at the old heritage. Such a critical look started already in the 13th–14th centuries with the scholastics, and was an important factor leading to Renaissance. Was the absence of discontinuity a disadvantage for the Chinese and the Indians?

The load from the past has been summarized by Kosambi: 'The absence of logic, contempt for mundane reality, the inability to work at manual and menial tasks, emphasis upon learning basic formulas by rote, with the secret meaning to be expounded by a high *Guru*, and respect for tradition (no matter how silly) backed by fictitious ancient authority had a devastating effect upon Indian science.'[57]

The various corrosive factors seem to have been operating from the last centuries of the first millennium, though their effect was seen much later. As Nehru[58] has remarked, during Akbar's time, 'India to all outward seeming presented the spectacle of not only a brilliant court, but of thriving trade, commerce, manufacture and crafts. In many respects, the countries of Europe would have seemed backward and rather crude to an Indian visitor then. And yet the dynamic quality which was becoming evident in Europe was almost wholly absent in India . . . A civilization decays much more from inner failure than from external attack. It may fail because in a sense it has worked itself out and has nothing more to offer to a changing world, or because the people who represent it deteriorate in quality and can no longer support the burden worthily . . . '.

Some comments on the western traditions supposedly responsible for the rise of modern science in Europe

Finally, it may be appropriate to comment very briefly on some of the contributory factors that are often mentioned in the context of the rise of modern science in Europe.

Rise of modern science was a unique happening, that took place in Europe. There has been a lot of post-facto rationalization of this development[59]. The search has been for developments which took place uniquely in Europe, so as to make a case that modern science could arise only as a concomitant of such developments and, therefore, in Europe and nowhere else. Developments like Reformation and Renaissance are often mentioned as contributory or triggering factors. It is good to remember, however, that Copernicus was not only a catholic but a canon in the Roman Catholic Church and that high dignitaries of the Church were associated with the publication of his book. Galileo was also a Roman Catholic and ventured into the realm of theology by attempting to show that the Copernican system was consistent with a fair interpretation of the words of the Scriptures. And Martin Luther mounted a vicious attack on Copernicus. The Catholic Church, it is well known, put the books of Copernicus and Galileo on the *Index*.

Anthony[60], a biographer of Newton, quotes Butterfield to make the point that the ancient Greek thought, through Arab translations, Renaissance, Reformation, etc., did not change the mode of thinking of people as scientific revolution itself did.

Butterfield has, in fact, observed, 'since that (i.e. scientific) revolution overturned the authority in science not only of the middle ages but also of the ancient world – since it ended not only in the eclipse of scholastic philosophy but also in the destruction of Aristotlean physics – it outshines everything since the rise of Christianity and reduces the Renaissance and Reformation to the rank of mere episodes, mere internal displacements within the system of medieval Christiandom . . . '[61].

The question then arises if one has been overemphasizing factors like Renaissance, Reformation and changes in the mode of thinking of people as the prime contributors to the rise of modern science in Europe.

And Bertrand Russell has observed:

'Although science was what interested (Francis) Bacon, and although his general outlook was scientific, he missed most of what was being done in science in his day. He rejected Copernican theory', even after the work of Kepler. 'Bacon appears not to have known of the work of Vesalius, the pioneer of modern anatomy, or of Gilbert, whose work on magnetism brilliantly illustrated the inductive method. Still more surprising, he seemed unconscious of the work of Harvey, although Harvey was his medical attendant!'[62].

It is also interesting to note the comments of Thomas Huxley on the influence of Baconian philosophy:

' . . . I do protest that, of the vast number of cants in this world, there are none, to my mind, so contemptible as the pseudo-scientific cant which is talked about the Baconian philosophy. To hear people talk about the great chancellor – and a very great man he certainly was – you would think that it was he who invented science, and that there was no such thing as sound reasoning before the time of queen Elizabeth . . . The method of scientific enquiry (did not originate with Bacon or his age) originated with the first man whoever he was, . . . '[63].

Butterfield[64] has commented that one of the aspects of history that is not sufficiently emphasized is that '*from the fourth to the twentieth century, one of the most remarkable aspects of the story – the most impressive conflict that spans 1500 years – is the conflict between Europe and Asia, a conflict in which down to the time of Newton's Principia, it was the Asiatics who were on the aggressive*'.

It is clear that some of the contributory factors held responsible for the rise of modern science in the West and for the East lagging behind need a fresh look.

Mukhopadhyaya[65] has written about two metamorphoses of the mind in the recent centuries, one among the Europeans, who appropriated science as a purely western product, as a most typical creation of thought of the Western civilization, and the other suffered by the colonial people, Indians in particular, which persuaded them that science was not a part of their civilization.

Mukhopadhyaya's thesis calls for a closer look.

Concluding remarks

It should be clear that the Project on the History of Indian Science, Philosophy and Culture should constantly keep in view the changing sociocultural–philosophical milieu in which science could have flourished in India during certain periods, and in which Indian technology could have been at the forefront internationally in certain domains down to the eighteenth century, and in which both became stagnant or declined during other periods. What were the external factors and what were the internal failures *which must not be allowed to repeat*? Were the internal failures on a broad front (science, philosophy, literature, art, architecture, . . .)? To the extent that the Project will succeed in unravelling these complex intertwining factors, it will provide a landmark in the history of the development of Indian science, philosophy and culture.

11. Related to this is the fact that in India, where mythology continues to play an important role in people's daily life, stories of mythological (and today's) personalities acquiring supernatural knowledge, skills, powers by *sadhana* continue to be believed by many people. We even have the phenomenon of a Prime Minister addressing an academic gathering and making a reference to our ancients having visited *Candraloka*.

42. Swami Ranganathananda, *Science and Spirituality*, Ramakrishna Math, Hyderabad, 1982; also *Science and Religion*, Advaita Ashram, Calcutta, 1982, vol. 1, p. 22. Note, however, that Alberuni has elsewhere praised the Hindus and their contributions to the science. He even learnt Sanskrit and translated some of the works.
43. Quoted by Majumdar, R. C., in *History and Culture of Indian People*, Bharatiya Vidya Bhavan, New Delhi, vol. II, Chapter XXIV.
44. Varahamihir, quoted by Alberuni in Ref. 33, pp. 22–23.
45. Daniel, J. Boorstein has drawn attention to the fact that 'despite an uncanny reverence for the written word, the Arabic world resisted the opportunities of the printing press', and remarks that 'fear of blasphemy and heterodoxy kept the printing press out of the Muslim world for centuries'. See Boorstein Daniel, J., *The Discoverers*, Vintage Books, 1985, pp. 539–547.

46. Thapar, Romila, *A History of India, loc. cit*, p. 149.
47. Bose, D. M., Sen, S. N. and Subbarayappa, B. V. (eds.), *A Concise History of Science in India*, Indian National Science Academy, New Delhi, 1971, pp. 484–485.
48. Altekar, A. S., *Education in Ancient India*, The Indian Bookshop, Banaras, 1934, pp. 198.
49. How effective was the ban until the 13th century? Until then, Indians had close interaction with West/Central Asia and SE Asia[50]. And it could not have affected Muslim scholars and traders. The Gujaratis were, in fact, the dominant ship-owning and trading community at Malacca at the end of the fifteenth century (see, for example, *The Suma Oriental of Tomé Pires*, Hakluyt Society, London, 1944, 2 volumes, translated and edited by Armando Cortesão, quoted in *South-East Asia: Its Historical Development*, by John F. Cady, Tata McGraw Hill, New Delhi, 1976).

53. It is a pleasure to thank B. V. Subbarayappa for a discussion on the contents of this paragraph.
54. It is interesting to read the announcement of the founding of a new University at Toulouse in 1229, which made a special mention that 'those who wish to scrutinize the bosom of nature to the inmost can hear here the books of Aristotle, which were forbidden at Paris'. Ref. 'New University-1229' in *A Random Walk in Science*, Institute of Physics, London, 1973, p. 15; the item being condensed from Thorndike, Lynn, *University Records of the Middle Ages*, Columbia University Press, 1944.
55. Ray, P. C. said in this context: 'The *Vedanta* Philosophy, as modified and expounded by Sankara, which teaches the unreality of the material world, is to a large extent responsible for bringing the study of physical science into disrepute. Sankara is unsparing in his stricture on *Kanada* and his system ... Among the people riden by caste and injunctions of the *Vedas*, *Puranas* and *Smrtis* and the like, cramped and paralysed, no Boyle could arise.' (quoted by Debi Prasad Chattopadhyaya in Ref. 3)

Council of Scientific & Industrial Research (CSIR), New Delhi, India

Advt. No. 6/95

Position: Director, National Aerospace Laboratories (NAL), Bangalore

CSIR, the premier agency established by the Government of India to undertake scientific and industrial research in the country, is looking for a suitable scientist/technologist for the post of Director for its National Aerospace Laboratories (NAL), Bangalore. NAL is devoted to carrying out application-oriented R&D work in aerospace engineering and related areas with particular reference to design, construction and operation of aircraft, maintenance and operation of important testing and analytical facilities and undertakes contract R&D work in its areas of activity.

The post carries the pay scale of Rs 5900–200–7300 plus allowances as admissible to Central Government officials. Consultancy remuneration. The appointment to the post will be on contract for a period of six years or superannuation, whichever is earlier.

For further details, please contact the Director-General, CSIR, Rafi Marg, New Delhi 100 001 (India), (Fax: 3710618, Telex: 031–65202 CSIR IN, 031–66147 CSIR IN, Gram: CONSEARCH, NEW DELHI).

Council of Scientific & Industrial Research (CSIR), New Delhi, India

Advt. No. 5/95

Position: Director, National Chemical Laboratory (NCL), Pune

CSIR, the premier agency established by the Government of India to undertake scientific and industrial research in the country, is looking for a suitable scientist/technologist for the post of Director for its National Chemical Laboratory (NCL), Pune. The Laboratory is devoted to carrying out research in different areas of chemistry, developing new technologies for gainful utilization of natural resources and assisting the chemical industry through consultancy, contract R&D and training.

The post carries the pay scale of Rs 5900–200–7300 plus allowances as admissible to Central Government officials. Consultancy is permitted without any ceiling on the annual consultancy remuneration. The appointment to the post will be on contract for a period of six years or superannuation, whichever is earlier.

For further details, please contact the Director–General, CSIR, Rafi Marg, New Delhi – 110 001 (INDIA), (Fax: 3710618, Telex: 031–65202 CSIR IN, 031–66147 CSIR IN, Gram: CONSEARCH, NEW DELHI).

Institute for Research in Reproduction (ICMR)

The Institute for Research in Reproduction is happy to announce a short-term training course on Techniques in Immunology, Cell Biology and Molecular Biology from 2 November 1995. The training course will cover the latest techniques in these areas.

Applications are invited from mid-career scientists/technologists (preferably below 40 years) working on regular positions in universities, national laboratories, research institutions and in-house R&D centres.

The candidates should apply giving details in the following format:

(i) Educational qualification, research experience, age
(ii) Present place and nature of work
(iii) Facilities for R&D available in candidate's laboratory
(iv) Present and future research interest of the candidate's laboratory
(v) How the candidate proposes to make use of the training in his/her research programmes.

About 12 candidates will be selected. The participants will not be charged registration fees. However, TA/DA will have to be met by the sponsoring institutions. Accommodation for outstation candidates will be made available at subsidized rates.

Applications duly sponsored and through proper channel should reach the Director/Convenor, Dr (Mrs) U. C. Hegde, Institute for Research in Reproduction, Jehangir Merwanji Street, Parel, Bombay 400 012 (Fax: 91–022–4139412) on or before 31 August 1995. Selected candidates will be informed by 15 September 1995.

Nuclear Science Centre

Inter-University Research Facility
(An Autonomous UGC Institution)

Advt. 3/95

Applications are invited for the following:

SCIENTIST TRAINEE (3 positions: one general, others one each reserved for SC & ST): M Sc in Physics, persons with M Sc before 1993 need not apply. Fixed stipend of Rs 2500 during the training period with free hostel-type accommodation for one year. If successful after training, may be placed in detector/cryogenics laboratory (grade Rs 2200-4000).

SCIENTIST (Atomic Physics), Grade Rs 3000–4500: Ph D in Experimental Atomic Physics, minimum 2 years of experience in accelerator-based research. Meritorious candidates with relevant experience may be considered for higher grade.

ENGINEER (Cryogenics), Grade Rs 3000–4500: B E (Mech.) or M Sc (Physics), minimum 4 years of experience in cryogenics. Hands-on experience on He refrigeration system is required. Familiarity with cryostats/gas handling system and computer-aided designing will be considered as added qualification.

ENGINEER (Experimental Facility Development), Scale Rs 3000–4500: B Tech (Instrumentation/ Electronics) after B Sc (Physics) or M Sc (Tech/Applied Physics) or M Sc (Physics with Electronics), minimum 4 years of experience in development of instrumentation and computer interfacing. Experience in both hardware and software is preferred.

Send curriculum vitae with complete details with photograph and attested marksheets from High School onwards and names of three referees. Information should reach **A.O. (Admn.), Nuclear Science Centre, Aruna Asaf Ali Marg, Post Box 10502, New Delhi 110 067**, within 30 days from the day of this advertisement.

GOVERNMENT OF INDIA
MINISTRY OF SCIENCE & TECHNOLOGY
DEPARTMENT OF SCIENCE & TECHNOLOGY

PROPOSALS INVITED FROM INDUSTRIES FOR PARTIAL FINANCIAL SUPPORT FOR DEVELOPMENT OF INSTRUMENTS

The Department of Science & Technology (DST) under its scheme on 'Instrument Development Programme' (IDP) has been promoting and supporting the programmes on indigenous development of sophisticated instruments. The Department has been providing financial support to R&D organizations for design and development of identified instruments in the areas of Analytical, Medical, Geo-scientific, Agri-electronic and Test and measuring instruments. Industries (private or public sectors) are associated with the projects from the very beginning to ensure commercial exploitation of the technology.

The Department now extends the programme inviting suitable project proposals from industrial firms having well-established in-house R&D units recognized by DSIR for partial financial support for development of identified instruments in the following areas:

1. Analytical instruments
2. Medical instruments
3. Geo-scientific instruments
4. Agri-electronic instruments
5. Test and measuring instruments
6. Laser-based instruments
7. Food processing instruments
8. Environment monitoring and pollution control instruments; and
9. Sensors

The individual firms should have good track record of R&D achievements for seeking financial support. Preference will be given to joint project proposals from industries and R&D organizations. However, the Department reserves the right to reject any proposal without assigning any reason thereof. For more information/guidelines about submission of project proposals, the interested parties may write to:

What can we learn from the croak of a frog?

For the common man, frogs bring on the image of slimy, creepy, ugly things that croak without a trace of decency. For the Indian undergraduate student of zoology, frogs must appear as having been created by God for the sole purpose of being used for teaching and learning how to dissect animals and study their anatomy. But like the princess in the fairy tale who kissed a frog and turned him into a prince, Debjani Roy and her students might well bring to the frog a large measure of respect and admiration.

On **page 265** of this issue, Debjani Roy, Bijoylakshmi Borah and Amarendra Sarma describe experiments that permit a deeper understanding of the role of frog calls in their courtship behaviour. Because of the feebleness of their calls and perhaps at least in part because of the gender of most previous researchers on frogs, the calls of the female frogs have largely been neglected. Most previous work has concentrated on male calls and has created the view that males advertise themselves so that females have no difficulty in finding them. The present study has made a special attempt to go beyond the din created by the male frogs and attempt to listen to what the females have to say. The recordings and analysis of the female calls suggest that females are calling in response to the males and in the context of courtship. Typical of males in general, the male frogs call as loud as possible in an attempt to get the attention of the females. On the other hand, the females' feeble call is probably testing the sensitivity of the males!

In any case this study suggests a much more active role for the female frog in matters of mate choice and courtship than has been hitherto suspected. This is reminiscent of the more general shift we are now witnessing, from a view of animal courtship based largely on male–male competition for access to the passive females towards a view where female choice has a significant role in deciding who mates with whom. That somebody has thought it worthwhile to leave the laboratory bench and the dissection tray and go to the inhospitable marshes at night, and that too in North East India, to learn from living frogs, augurs well for Indian zoology. There is so much to learn from the croak of a frog.

NMR: Fifty years on

Almost fifty years have passed since Felix Bloch and Edward Purcell independently reported the observation of nuclear magnetic resonance (NMR) in bulk matter. Conceived as an esoteric technique to measure nuclear magnetic moments accurately, hardly anyone in the late 1940s could have foreseen the impact that NMR was to make in the fields of chemistry, biology and medicine. The first sign that NMR was too useful to be left entirely to physicists came early on; the proton resonance frequencies in the samples used by Bloch (tap water) and Purcell (mineral oil) were different. Clearly, chemistry was at work, modifying Larmor precession frequencies. A more dramatic manifestation of the role of chemical environment in influencing nuclear resonance frequencies was provided in 1951 with the famous demonstration of three chemically shifted groups of proton resonances in ethyl alcohol by Arnold, Dharmatti and Packard. The last named was to go on to developing commercial NMR instrumentation, while Dharmatti was to introduce the NMR technique at the then fledgling Tata Institute of Fundamental Research (TIFR) in Bombay. Interestingly, the first magnetic resonance experiments in India were conceived and executed by G. Suryan in the Physics Department of the Indian Institute of Science, Bangalore, in 1950–51. By the early 1960s NMR was a critically important tool for structure determination in organic chemistry, with the hydrogen nucleus as the sole reported case of chemical environment. No chemistry department in the West would consider itself complete if it did not possess an NMR spectrometer (a condition that has now been reached in India also). Two problems, however, limited the range of NMR applications; sensitivity of detection of resonances and inadequate chemical shift dispersion in complex molecules containing large numbers of atoms. The introduction of Fourier Transform Spectroscopy in the late 1960s and the advent of superconducting magnets capable of providing high magnetic fields of requisite homogeneity allowed NMR to breach the barriers between chemistry and biology. Enhanced sensitivity now permitted detection of resonances from less abundant nuclei (^{13}C, ^{15}N), enhancing the information content of NMR studies. But more was to come. In the late 1970s following a suggestion by Jean Jeneer, the first two-dimensional NMR experiments were performed by Richard Ernst. Overlapping frequencies could now be resolved by spreading the information onto a frequency plane; more importantly correlations between coupled nuclei permitted identification of groups of spins characteristic of specific chemical groups. By the early 1980s there was a veritable flood of multiple pulse experiments; spectroscopists could now literally eavesdrop on intimate conversations between atomic nuclei in molecules. The convenient detection of nuclear Overhäuser effects (NOEs) permitted identification of spatially proximate (< 4 Å) hydrogen atoms, providing finally a firm handle for the determination of three-dimensional structures of molecules in solution. NMR was poised by the mid 1980s to enter an arena which had till then been exclusively dominated by X-ray crystallography: the field of biological structure determination.

The first pioneering study of bovine pancreatic trypsin inhibitor, a small 58-residue polypeptide by Kurt Wüthrich and his collaborators at the ETH in Zurich, was quickly followed by a deluge. The size range of proteins that can be studied by NMR methods has steadily increased with the incorporation of stable isotopes (^{13}C, ^{15}N), permitting multidimensional spectroscopy. Advances in NMR have paralleled the revolution in molecular biology, which permits ready production of recombinant proteins; the fusion of the two areas now promises to provide remarkably detailed information on biological structures in solution.

In India too, the sophistication of the available NMR methodology has slowly increased with the TIFR now housing spectrometers that operate at 500 and 600 MHz for proton resonances. In this issue (**page 243**) P. K. Radha *et al.* describe a structural study of the DNA binding domain of a proto-oncogene product, c-Myb, from *Drosophila*. The analysis of the NMR spectrum of the 160 residue polypeptide and the determination of the structure of a dodecameric nucleotide containing the segment recognized by the c-Myb protein using multidimensional NMR methods are described.

P.B.

INDIAN INSTITUTE OF SCIENCE
BANGALORE 560 012

Applications are invited for a FACULTY POSITION in the Department of Physics at the level of **ASSISTANT PROFESSOR** in the scale of Rs 3700–125–4950–150–5700.

Qualifications and Experience

Should have a Ph D in Physics with first class in the preceding degree; a good record of publications and 3 years of postdoctoral teaching/research experience (relaxable in exceptional cases) in the field of optical physics. The candidate should have specialized in the broad area of experimental optical physics and nonlinear optics.

He/she is expected to make optimal use of the major existing facilities in a well-equipped laser laboratory of the Department.

Details and application form can be obtained by sending a written request accompanied by an IPO for Rs 10/- drawn in favour of the Registrar (free of cost to SC/ST candidates on production of caste certificates) along with a self-addressed stamped (Rs 2/-) envelope of size 28 × 18 cm on or before 30 August 1995.

Completed applications along with copies of certificates, publications and a research plan for the next few years should reach the Registrar on or before 15 September 1995. Referees may be requested to send their considered reports to the Registrar.

R(IA)308-14/95

CURRENT SCIENCE

Volume 69 Number 3 10 August 1995

CORRESPONDENCE

Revitalization of Indian science

A draft paper[1] prepared by the Indian Academy of Sciences on science education, National Science University (NSU) proposal of Mahajan[2], and the dedication[3] to the nation of the Jawaharlal Nehru Centre for Advanced Scientific Research (JNCASR) on 4 March 1995 have not only commonality in the declared objectives of achieving excellence in science, they also display identical mind-sets of the persons involved. My purpose is two-fold: to delineate some of the vexed questions related with the Indian science by analysing these examples[1-3], and to offer suggestions for small corrective measures to check the degeneration effectively.

The debate on the NSU proposal has been mainly centred on three issues discussed below:

1. *The Role of the NSU.* The basic premise is that a talented few should be nurtured by providing them with the support and facilities comparable to the best in the world. This is not new, and as noted by many readers the so-called elite institutions have been established based on this premise without having made much impact on the state of science done in our country. As for catching up and competing with the frontline research areas, the path-breaking or sufficiently influential contributions from India have been almost nil. If we examine the names of the scientists comprising the top body in any heavily funded enterprise ostensibly aimed at excellence, then we find almost the same set of persons with minor changes here and there. Obviously, the policy makers believe that there are only a handful of such high-calibre competent scientists. As a corollary, if the NSU comes into being, the honorary faculty of the JNCASR or such other 'eminent' scientists will be appointed in that also. Therefore, assuming that ideally whatever is proposed in Mahajan's scheme gets implemented, there will be marginal impact on Indian science, there will be no depletion of faculty from the universities, and for ordinary scientists it will be irrelevant. Why should we be alarmed? The JNCASR was established without any open discussion. Why? Is the NSU proposal being criticized because the group of powerful scientists perceive this as a threat to their monopoly? One talks of NRI arrogance, but have the Institute scientists ever realized their own arrogant behaviour towards the University and college teachers? The Academy paper[1] approves the recommendations made by the Planning Commission Working Group for a three-tier scheme. Tier I is aimed at 0.5% of the estimated total UG science students in a year, with the allocation of funds of the order of 22% of the total grant. And in tier III 83% of the students will also get almost the same amount, i.e. 22%. I cannot imagine if any idea can be worse than this, and fully endorse Sriram's rejection[4] of this 'few highly talented' syndrome.

2. *Criticism of science establishment.* Many readers have felt offended by sweeping condemnation of feudal science establishment (or coterie) by Mahajan. While it is true that the language used by Mahajan is unpleasant (or pedestrian according to Murthy[5]), the criticisms are valid. The Academy paper[1] makes a general statement without any study: 'In most universities and affiliated colleges, one finds low educational standards and a poor academic environment.' According to Sriram[4]: 'In fact, scientists in our country miss no opportunity to declare that our universities have low standards and poor academic environment.' Not only commoners do not need resources, they can be denied basic dignity! From my experience I have found that rapid decline in teaching has occurred primarily due to misplaced unimaginative policies and schemes formulated by eminent scientists, i.e. centres of excellence, frontline research, and promotions linked with Ph D. Ironically, such policies have been lauded in ref. 1. In the centres of excellence, costly equipment are inaccessible to the students and teachers, the personnel appointed are mediocre and pliable, the so-called frontline research activities pursued are done in isolation within the faculty, and control of funds in few hands leads to exclusivity and negative impact on the general teaching environment.

Returning to the existence of coterie, I shall give a recent example of powerful coterie in action. On 16 February 1995, during a Discussion Meeting of the JNCASR at Banaras Hindu University, C. N. R. Rao delivered an evening talk on Indian science, in which he was harshly critical of CSIR laboratories, their Directors and Bhatnagar Prize winners. Although several of them were present, none expressed even mild resentment. Interaction with students and teachers of the eminent scientists was cosmetic. The whole exercise seemed to be a demonstration of the powerful coterie.

In my opinion the crucial factor responsible for the creation of this feudalism in science is the exalted position granted to the science administrators close to the political power, and lack of transparency in the policy matters. For example, Arunachalam[6] has made very pertinent comments on the election of the Secretary, Department of Science and Technology (DST), as the new President of the Academy.

3. *Patriotism.* Swadesh Mahajan is a nonresident scientist in the US, so why not attack his patriotism? Many comments have appeared[5,7] implying that the concern shown for India by NRIs is of

doubtful nature; their hidden aim is to promote their self-interest. I think NRIs are not necessarily opportunists, and those working in India are not necessarily inspired by nationalism – we must recognize this. It is better to remember that for C. V. Raman, J. C. Bose and M. N. Saha patriotism was an article of faith which came to them naturally. Bhabha essentially introduced the concept of what I call contractual nationalism in science. Most of the scientists who have returned to India have done so after prolonged bargains. And the patriotism of quite a few top scientists is so shaky that slight dilution in their status or facilities and funding makes them repent their stay in our country. I refer to an interview[8] and quote C. N. R. Rao's reply: 'Probably I should have left India long ago'.

Science establishment

Science education cannot be discussed in isolation; support and funding for science and technology cannot be divorced from the socioeconomic conditions of the people on the one hand and obligations of the scientists towards the society on the other. For a serious discussion, obsession with excellence, and undue importance given to science administrators and managers must go. Excellence in the midst of common people emerges naturally, and it can be easily identified if the intentions are honest. Raman demonstrated this in his life, and fortunately his views on 'centre of excellence' have also been recorded by Ramaseshan[9]. I quote a few sentences: '... I strongly believe that fundamental science cannot be driven by instructional, industrial, governmental or military pressures .... Among the many qualities called for in a person who assumes this responsibility are scientific integrity, vision, receptiveness to new ideas and the enlightened outlook to let younger people grow unhindered to their full height...'

The scientists in top positions have shown ideological elasticity to suit political leadership of the day. To take a very important example, at the Prime Minister's initiative in 1976, Indian Science Congress focused attention on rural development. Since then started the convention of focal themes. The idea as such is quite good. But what has happened to this? The task forces were established, and recommendations for follow up actions were made[10]. I list some of them: '... Social responsibilities of scientists; Assessment and improvement of biofertilizers utilizing genetic engineering techniques wherever possible and the possibility of their utilization on a large scale in agriculture; Protection of tribals and weaker groups from exploitation of their natural resources; Universities and institutions should be adequately funded in order to (a) revise the standard of scientific education, (b) provide long- and short-term training for young scientists to deal with socioeconomic problems, and (c) operate extension wings to enable laboratory findings to reach the rural areas; Engineering expertise should be pooled and tied up with prime plant manufacturers for standardization of plants and equipment, which may reduce lead time and optimize investment.' These are very significant and relevant suggestions for the country, but the science establishment has not shown any enthusiasm and commitment to implement them. Today economic liberalization has led top scientists to find virtues in privatization of higher education, university–industry interaction, marketism of R&D, and shift from rural people to limiting 'tertiary education' for selected few. The conclusion is that not only have they (i.e. top scientists) failed, they cannot be trusted for an independent and fair stand.

It has been advised that the science administrators who have failed to deliver the goods should retire[11], and the demand for a white paper has been made by C. N. R. Rao[12]. Both the suggestions deserve to be implemented.

Corrective measures

Attention is drawn to the suggestions made earlier[13] with some clarifications here. The reason for the abolition of centres of excellence in universities has already been elaborated in the present article. However, in case of doubts their performance and the psychological impact of these centres on the rest of the faculty may be evaluated in open and transparent manner. The newly set up National Accreditation and Assessment Council of the UGC may look into this matter. I shall briefly state few more corrective measures. No person after retirement should be appointed on any administrative, Government's policy-making body or in the selection committees. The system of students' union and teachers' association in the universities and colleges should be abolished; instead, a scheme for redressal and a vigilance council may be formulated. The hierarchical system of teaching positions should be discontinued. To check inefficiency and corruption in the administration, a computerized system and reduction of present ministerial staff to less than 25% should be considered.

Role of academies

In a recent editorial candid observations about the Academy have been made by Balaram[14], and first report on higher education by the Indian Academy of Sciences has been published[1]. It is interesting to note that in UK a group called National Academies Policy Advisory Group was established in 1992, and the first report has come out on Intellectual Property and the Academic Community[15]. Whether our Academy has been inspired by that is not important, the step taken is most welcome. S. W. Hawking was elected FRS in 1974 'while holding the lowly position of research assistant at Cambridge'[16]. Perhaps the Indian Academies need to be made broad-based, and to learn from such examples for recognizing excellence. Arunachalam's comment[6] merits serious consideration. I think as a policy the office bearers of the Academies should not be chosen from amongst those holding administrative posts in the government.

In my opinion, the role of Academies in revitalizing Indian science and education can be very profound. Awareness, action and accountability could be the focus of attention.

Awareness. Information dissemination on policy matters, and forum for discussion and debate on the issues. *Current Science* has done praiseworthy beginning in this direction. The editorial[17] has made explicit this policy; however, I may remark that even now only less than 10% of the space is devoted to this aspect (e.g. less than 90 pages out of 976 pages in volume 66 (1994)), which includes all categories of articles published on the policy matters. Further the reach of the journal is limited; therefore, a cheap volume of reprint collection of the articles published during the last 3–4 years on this topic may be published by the Academy for students and teachers in

colleges. A scheme whereby the subscribers of *Current Science* may be motivated to gift one year subscription to someone in colleges may be initiated.

Action. The Academies can do certain things without depending on the government policies. For example, making available small grants for writing books to college teachers, and setting up of a national teachers scheme. In the latter case, the fellows selected as national teachers shall be required to spend a minimum of one month in a college, and three months in an academic year at different colleges. During their stay, formal lectures and informal interaction with the students and teachers will be their main duty.

Accountability. Corruption in various forms has become rampant in research and teaching. The Academies can play a very effective role in dealing with this problem. Scientists and Academics found guilty in plagiarism or other frauds[18] can be blacklisted: their work will not be published, their fellowships or titles awarded by the academies shall be withdrawn, and their names along with their malpractices shall be made public.

Conclusion

We have enough strength and capability, which need to be properly utilized; there are many creative minds, they only need to be identified. The sense of belonging and involvement in the system by all ordinary scientists and Academics should be cultivated. Frustration, helplessness and servile mentality must go; obviously, hard and unpleasant (for few) actions may be necessary for that to happen.

NEWS

1994 Kalinga Prize

The 1994 Kalinga Prize for the popularization of science has been awarded to Nikolai Nikolaevich Drozdov, Associate Professor of Biogeography at the Moscow State University.

Established by UNESCO in 1951, it is an annual award of £1000 based on a grant to UNESCO from B. Patnaik of the state of Orissa, India, the founder and President of Kalinga Foundation Trust. With the 1994 awardee, the tally now stands at 49 personalities from 19 countries (Jain, N. C., *Curr. Sci.*, 1994, **66**, 618–620).

A graduate of Moscow University in 1963, Dr Drozdov has done his doctorate in 1968 on the ornithofauna of the deserts of the USSR.

While working at the Australian National University (Canberra), he published a book called *The Flight of the Boomerang* about his journey through Australia, about animals, nature and nature conservation. It instantly became a best-seller and over 100,000 copies of its two editions published in 1980 and 1988 were sold out within a couple of weeks of its release. For the last twenty-three years Dr Drozdov has been presenting a bimonthly television programme called *In the World of Animals.* This highly popular one-hour programme on animal life in the vast CIS territory is watched by approximately 200 million viewers. In 1992 he won the **Golden Panda** for outstanding achievement at the Wildscreen Festival in Bristol. In 1989 he was included in Global 500, a list drawn up by the United Nations Environment Programme of the world's leading ecologists and specialists in environmental protection.

New appointments

Dr V. S. Ramamurthy, 53, has taken over as Secretary of the Department of Science and Technology in place of Dr P. Rama Rao on 1 July. Ramamurthy, a nuclear physicist, was earlier the Director of the Institute of Physics, Bhubaneswar.

Dr R. A. Mashelkar, 52, has taken over as Director-General of the Council of Scientific and Industrial Research in place of Dr S. K. Joshi on 1 July. Mashelkar, a chemical engineer, was the Director of the National Chemical Laboratory at Pune.

Oxide electronics

C. N. R. Rao

Metal oxides have emerged as promising electronic materials of the 21st century.

Silicon occupies a preeminent position in electronics today and this unique status of Si will probably remain for many years to come. Compound semiconductors such as GaAs were considered to be good candidates to replace Si because of their versatility, but this is far from happening. Yet, one is tempted to ask the question 'Will there be a material or a class of materials as good as or superior to silicon?'. Considering the wide range of properties exhibited by them, metal oxides would appear to be the likely contenders. The nature of bonding in oxides can vary anywhere between ionic and metallic or covalent. Oxides also exhibit a phenomenal range of electronic and magnetic properties[1,2]. Thus, we have oxides with metallic properties (e.g. RuO_2, ReO_3, $LaNiO_3$) at one end of the range and oxides with highly insulating behaviour (e.g. $BaTiO_3$) at the other. There are also oxides that traverse both these regimes with change in temperature, pressure or composition (e.g. V_2O_3, $La_{1-x}Sr_xCoO_3$). Interesting electronic properties also arise from charge density waves (e.g. $K_{0.3}MoO_3$), charge ordering (e.g. Fe_3O_4) and defect ordering (e.g. $Ca_2Mn_2O_5$, $Ca_2Fe_2O_5$). Oxides with diverse magnetic properties anywhere from ferromagnetism (e.g. CrO_2, $SrRuO_3$, $La_{0.5}Sr_{0.5}MnO_3$) to antiferromagnetism (e.g. NiO, $LaCrO_3$) are known. Many oxides possess switchable orientation states as in ferroelectric (e.g. $BaTiO_3$, $KNbO_3$) and ferroelastic (e.g. $Gd_2(MoO_4)_3$) materials. No discovery in solid-state science has created as much sensation, however, as that of high-temperature superconductivity in cuprates[3]. Although superconductivity in transition metal oxides has been known for some time, the highest T_c reached was around 13 K; we now have oxides with T_c's in the region of 160 K, which is not far from the lowest temperature recorded on earth (183 K). The discovery of high-T_c cuprates has focused worldwide attention on the physics, chemistry and materials applications of metal oxides.

Many applications of oxide materials in electronics are already known. They range from the use of oxides as insulators, capacitors, piezo-electric and pyroelectric materials, sensor materials, varistors, solid ionics, transparent conductors, and in magnetic and optical devices. In such applications, oxides are used in the form of bulk solids or thin films, generally in polycrystalline form. Fine ceramic technology is based on the control of grain size on the micrometer scale. Use of nanoparticles of oxidic materials is also gaining importance. With the progress in microelectronics, there has been much interest in the fabrication of thin films, especially in the epitaxial (high-quality single crystal) phase. A current concern in the development of large integrated silicon electronics is focused on high dielectric constant oxide films for capacitors and nonvolatile memories. In this context, heteroepitaxial growth of perovskite-type oxide films on silicon substrates is of great interest. Extensive investigations are being conducted for this purpose by employing various methods such as vacuum evaporation, sputtering, chemical vapour deposition (CVD), sol-gel process, pulsed laser deposition, and molecular beam epitaxy (MBE). Films fabricated hitherto are by no means exotic and possess crystal structures of known perovskites, possibly with minor modifications.

The phenomenon of giant magnetoresistance (GMR), that was known earlier in metallic bilayers and magnetic semiconductors, has recently been found to occur in oxides as well. In the last year, there has been intense research on perovskite oxides of the type $La_{1-x}A_xMnO_3$ (A = alkaline earth) exhibiting GMR[4]. GMR is found in bulk oxides as well as in films and this property will clearly be exploited for several applications.

One of the highlights of advanced electronics research today relates to artificially designed structures to test device concepts based on quantum effects (quantum dots, wires and wells). For this purpose, investigations on atomic control and characterization of heterostructures are underway in many laboratories. These structures are all based on Si and related materials. Until recently, such atomically engineered oxides were not explored and were considered impossible. The situation has, however, changed since the discovery of high-T_c superconductors. The potential of oxides as advanced electronic materials has enhanced enormously because of the

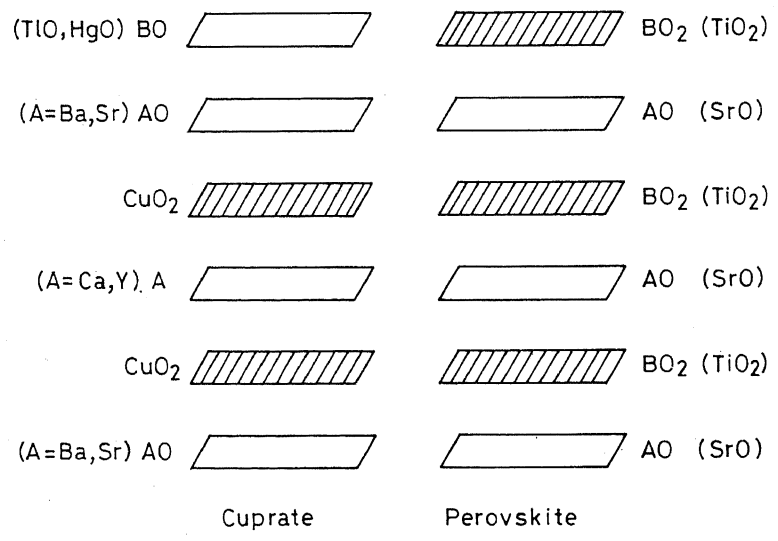

Figure 1. Layered lattice structure of perovskites and cuprate superconductors.

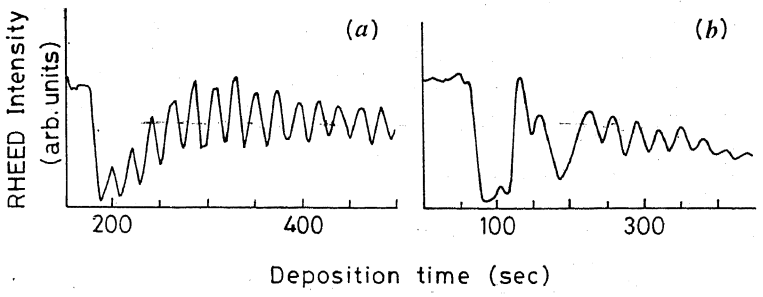

Figure 2. RHEED oscillations (0.4 nm) observed during the epitaxial growth of (*a*) $SrTiO_3$ (0 0 1) and (*b*) $BaCuO_2$ (0 0 1) on $SrTiO_3$ (0 0 1). Growth units are SrO/TiO_2, respectively (after Kawai *et al.*[5]).

possibility of growing novel or even unknown oxides layer by layer. It should be possible to fabricate a variety of hybrid devices and stacked unit cells or layers of perovskites which have good lattice matching with oxide substrates besides Si. For example, layered cuprate superconductors can be constructed or modified by depositing two-dimensional lattices (or layers) of different compositions chosen appropriately. In Figure 1, we show layered lattice structures related to perovskite oxides and high-T_c cuprates. The quality of such lattices is established by RHEED, RBS, STM, AFM and other techniques. A typical example of atomically controlled epitaxy of oxides is provided by $BaCuO_2$, which is a layered cuprate[5]. In Figure 2, RHEED oscillations obtained in the growth of such oxide layers are shown.

The wide range of properties of oxide systems certainly seems attractive compared to the Si/SiO_2 system, where the oxide can only provide it insulating characteristic. Valence control and impurity doping, readily accomplished in the case of Si, should be possible in oxides as well. In the short term, however, it should be possible to fabricate superconductor–insulator-superconductor (SIS) tunnel junctions exhibiting clear I–V hysteresis above 77 K. Such an SIS junction would be useful in switching devices which are expected to work faster than conventional transistors. It should be noted that there has already been success in fabricating simple devices using superconducting films or grain boundary and step edge junctions[6,7]. The use of oxides in combination with Si has also several possible applications in integrated devices. Clearly, there is much to be done in exploring oxides for electronic applications and in designing oxide superlattices with unexplored quantum functions. We have to find ways of doping, controlling valency and attaining the right carrier mobilities as well as in designing the right structures.

The importance of oxide electronics has been recognized widely in Japan, where there is considerable investment in this area. A large number of chemists, physicists and engineers are working on the various aspects of metal oxides, starting from synthesis and characterization to device applications. The Japanese consider oxides as electronic materials of the 21st century. In Tokyo Institute of Technology alone, a dozen or more professors work in this area. It is highly desirable that strong interdisciplinary groups in this country are encouraged and supported to work on various aspects of oxides.

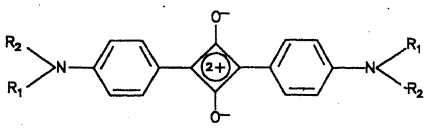
Noncentrosymmetric monolayers from centrosymmetric molecules – A fresh approach to materials for frequency doubling

T. P. Radhakrishnan

The age we live in is often called the 'electronic age'. Some recent developments in physics, chemistry, materials science and engineering, however, indicate that a 'photonic era' is not too far in the future, when the role of electrons in information technology will be played much more efficiently by photons. Signs of the transition can already be seen, e.g. in fibre-optic communication systems utilizing electrooptic devices; many believe that all-photonic devices will soon appear. These devices for light transmission, processing and storage would be based on a variety of nonlinear optical (NLO) phenomena. The nonlinearity refers to the second- and higher-order terms in electric field (E) in the expres-

sion for the bulk electric polarization ($\boldsymbol{P}$) of a medium. $\chi^{(1)}$ refers to the linear electric susceptibility:



$$\boldsymbol{P} = \chi^{(1)}\boldsymbol{E} + \chi^{(2)}\boldsymbol{E}\cdot\boldsymbol{E} + \chi^{(3)}\boldsymbol{E}\cdot\boldsymbol{E}\cdot\boldsymbol{E} + \ldots$$

and the other $\chi^{(n)}$ produce the different NLO effects; for example, $\chi^{(2)}$ leads to phenomena such as frequency doubling, also called second-harmonic generation (SHG). In a centrosymmertric medium, reversal of $\boldsymbol{E}$ should cause exact reversal of $\boldsymbol{P}$, and, as seen from the above expression, this is possible only if all $\chi^{(n)}$ with even n are zero. In other words, nonzero even-order χ can be realized only in noncentrosymmetric systems. Frequency doublers in use today employ inorganic crystals like potassium dihydrogen phosphate, lithium niobate and β-barium borate which have noncentric arrangement of the atomic lattice. Recent efforts have been directed at exploiting the large hyperpolarizabilities of selected organic molecules (like donor–acceptor-substituted benzenes, quinones, stilbenes, etc.) gathered in a suitable noncentrosymmetric array in a crystal, polymer matrix or thin film. Large molecular hyperpolarizabilities which lead to high bulk $\chi^{(2)}$ values are usually associated with strong intramolecular charge transfer in the molecular dipoles.

Obtaining a noncentrosymmetric array of molecules is a challenging problem. A noncentrosymmetric molecule with a permanent ground state dipole moment does not guarantee a noncentrosymmetric crystal lattice. On the contrary, they often form centrosymmetric crystals. However, it is the common experience so far that if one is to fabricate noncentrosymmetric lattice, one should build it with a noncentrosymmetric molecule, not a centrosymmetric one, though there are rare exceptions where centrosymmetric molecules with octupolar moments have formed noncentric lattices which showed moderate SHG. Crystal engineering utilizing H-bond interactions, chirality, etc., to build noncentric lattices, growth of Langmuir–Blodgett (LB) films of the X or Z type, where molecules are deposited in a head-to-tail fashion and electric field poling of molecular dipoles embedded in a matrix or attached to polymer chains are some of the common approaches to obtain noncentric arrangement necessary for SHG materials.

With this background the recent report by Ashwell and coworkers[1] on the detection of very strong SHG from centrosymmetric squarine dye molecules (Figure 1) deposited as LB films comes as an interesting surprise. Crystal structure of **1** is found to be centrosymmetric, belonging to the $P2_1/c$ space group and the diphenyl-substituted squarine moiety is flat and centrosymmetric. As expected, the crystals showed no SHG but the LB films (though of poor quality) were found to be SHG-active. Ashwell and coworkers report that **2** and similar systems (with R = other alkyl groups) provide better films and reproducible SHG which is among the highest seen so far in LB films. Reflectivity studies indicated that the LB films consisted of monolayers with the chromophores lying nearly parallel to the substrate surface. Absorption spectra of the films showed characteristic bands due to intermolecular charge transfer in the 660–690 nm range depending on the film deposition pressure.

The crystals of **1** consist of noncentric chromophore dimers which arrange themselves in a centrosymmetric lattice. The authors, therefore, suggest that in the LB films of **2** and similar molecules, noncentric dimers may be present which, however, form a noncentrosymmetric array, thus enabling $X^{(2)}$ to be nonzero. Since the chromophores themselves are centrosymmetric, intramolecular charge transfers do not contribute to SHG. Interfacial effects cannot give rise to such strong SHG as seen in these LB films. Therefore, the authors attribute the strong SHG to intermolecular charge transfer interactions in the dimer units. These charge transfers occur between the dialkylaminophenyl group of one molecule and the squarine moiety of the other in the dimer unit. It is also notable that a good correlation exists between the absorption wavelength variation from 656

1 $R_1 = R_2$ = butyl

2 R_1 = methyl, R_2 = hexyl

Figure 1. Squarine dye molecules deposited in LB films by Ashwell *et al.*[1].

to 694 nm and the increase of SHG efficiency as a function of film deposition pressure. The compression process appears to influence strongly the orientation of the chromophores (or chromophore dimers) in the noncentrosymmetric array.

The LB film structure is not fully understood and, therefore, the mechanism by which the strong SHG arises has to be treated as tentative. Film characterizations were carried out on samples deposited on silver-coated slides, but different film characteristics for samples deposited on plane glass slides used in the SHG studies cannot be ruled out. Though some of these questions remain, the discovery of Ashwell and coworkers is notable for the following important insights gained. There is no reason to believe any more that centrosymmetric molecules cannot be coaxed into noncentric arrays useful for SHG. Intermolecular charge transfers can be an efficient mechanism to obtain large bulk optical nonlinearities. This work is likely to initiate a fresh approach to the fabrication of quadratic nonlinear optical materials. The technological promise of these materials is enticing enough to justify detailed investigation and appraisal of such novel ideas.

Targeting RNA in the cell

S. C. Lakhotia

The typical textbook description of a cell suggests that the genetic information residing in the nuclearly located DNA is transcribed in a regulated fashion and the resulting RNA is processed and transported to cytoplasm, where it is translated and the protein so made is translocated to specific parts of the cell for its structural and/or enzymatic role in the cell's phenotype. However, such simplistic descriptions do not reveal the highly ordered three-dimensional organization of a cell, where every molecule, in fact, has a defined dynamic location. While localized distribution of at least certain specific RNAs in cells had been known for some time, it has become possible only recently to ask how this localized distribution is actually achieved. Application of molecular cell biological approaches has permitted newer insights into the three-dimensional molecular architecture of a cell and how the various molecules are vectorially transported within it to achieve the polarities that a cell has.

It is now clearly established that not only is the primary act of transcription of a given DNA sequence regulated with a certain degree of fidelity, the processing and transport of the transcripts is also a highly regulated process. Studies during the past few years have shown that certain RNAs are targeted to specific subcompartments of the cell where their translational product/s are immediately needed. The importance of such highly specific subcellular localization of RNA and its protein product is most obvious in the zygote cell since the unfolding of the entire body organization during the development of the zygote depends on the molecular asymmetries that are established in the unfertilized or the newly fertilized egg. In what follows, we discuss some recent studies which are attractive for their use of novel combinations of microscopic and molecular techniques to examine (i) the structural components of a cell that transport RNA away from the site of synthesis in nucleus to its final location in a specific subcompartment of the cell, (ii) the signals that tell the cellular transport machinery where to deliver the given RNA molecule and (iii) the components that keep the RNA anchored to the desired subcompartment.

mRNA transport and localization in cells: visuals of the process and mechanism

It has been known that the β-actin protein as well as its mRNA colocalize at the leading edge of lamellipodia in a variety of cell types[1–3]. Apparently, the highly localized distribution of β-actin mRNA in these cell types provides for the compartmentalization of actin synthesis. It has been shown in several cases[4] that the RNA localization signal (zipcode) is present in the 3′ untranslated region (3′ UTR) of mRNA. Kislauskis *et al.*[5] identified the specific 'zipcode' sequence/s by fusing different lengths of the 3′ UTR of β-actin to the reporter β-galactosidase (*lacZ*) gene; this allowed a direct visualization of the intracellular distribution of β-galactosidase activity in transfected chicken embryo fibroblasts by simple X-gal (a chromogenic substrate for β-galactosidase) staining. It was shown that two sequence elements in the 3′ UTR of β-actin mRNA provided the peripheral localization signal to the heterologous β-galactosidase mRNA so that in cells transfected with such chimeric constructs, X-gal staining revealed blue colour at the same place where the β-actin protein was. Of these two peripheral localizing signals, a 54-nucleotide sequence was the main 'peripheral RNA zipcode' while the homologous but less active 43-nucleotide sequence, present further downstream, was composed of 'zipcode elements'. The basic elements of these 'zipcodes' were identified as AATGC and GGACT, which act in concert so that multiple copies of each provide a stronger peripheral localization signal. These authors suggest that the high A/C content in the 54-nucleotide zipcode may also have a role in peripheral localization of the β-actin mRNA. It was also seen that addition of complementary oligonucleotides against the RNA zipcode delocalized the endogenous β-actin mRNA and altered the organization and shape of lamellipodia and stress fibres, without affecting levels of the β-actin mRNA or protein; this showed that the localization of β-actin mRNA is essential for the phenotype of these cells.

An answer to how the mRNA molecules may possibly remain anchored in cell cytoplasm, essential for the localized distribution, has been provided in a very ingenious study by Bassell *et al.*[6]: single mRNA molecules were seen with an unprecedented resolution and accuracy to be anchored on actin filament intersections in fibroblasts. To achieve this feat, they used different sized gold particles to 'see' simultaneously, at the ultrastructure level, the labelled oligo-dT probe hybridized *in situ* with polyA tail carrying mRNAs and the antibody bound to actin fibres. Furthermore, the oligo-dT probe hybridized with the polyA tails of cytoplasmic mRNAs was used as primer for *in situ* reverse transcription; the *in situ* extended cDNA chains and the oligo-dT–polyA hybrids were covisualized by immunobinding of different sized gold particles. These results unambiguously demonstrated the localization of individual mRNA molecules specifically at intersections of actin filaments. These studies also revealed that the mRNA at these intersections remains in a circular rather than an extended or linear conformation; this may help explain the interactions between the 3′ and 5′ ends of mRNA that are important in regulating translation.

Directed transport and localized anchorage of mRNA during oogenesis in *Drosophila*

The stages of oogenesis provide a remarkable material for study of localized RNAs and the mechanisms that regulate the spatial order in the distribution of different transcripts in different regions of oocyte. It is this asymmetric but highly ordered distribution of different macromolecules in the egg that determines the subsequent cascades of determination events in early embryonic development. The large body of genetic data has made *Drosophila* eggs a material of choice for such studies.

During oogenesis in *Drosophila*, the growing oocyte is nourished and provided with all its RNAs and proteins by the 15 sister nurse cells and the surrounding follicle cells. The nurse cells synthesize the different RNAs and proteins which are transported through intercellular connections to the growing oocyte, where each of these gets localized in a highly ordered and reproducible manner. Among the several different RNAs that are localized in *Drosophila* oocyte and have important roles in embryonic development, those produced by the *bicoid*, *oskar* and *nanos* genes are critical for anterior–posterior axis determination[7]. The *bicoid* (*bcd*) RNA in mature oocyte is localized to the anterior margin and remains confined to the anterior region of embryo, where it directs the development of anterior structures[7,8]. Likewise, transcripts of the *nanos* and *oskar* (*osk*) genes are located at the posterior pole of the egg and are crucial for the posterior development[7].

The localized distribution of these nurse-cell-produced transcripts in oocyte results from a series of events during oogenesis; a number of earlier acting genes are known to affect movement and the characteristic localization of these polarly located early determinants or morphogens[7]. The *staufen* (*stau*) gene plays a critical role in the last step of *bcd* RNA localization, i.e. its release from the egg cortex of mature oocyte into anterior cytoplasm of activated egg and early embryos. *stau* is also important in the final stages of posterior localization of the *osk* mRNA in the egg[7].

Pokrywka and Stephenson[9] found that *bcd*, *osk* and certain other RNAs were dynamically associated with cytoskeletal elements during different stages of oogenesis. These authors developed a simple procedure for fractionation of detergent-insoluble cytoskeleton from the soluble components of developing oocytes and showed that the association of *bcd* RNA with detergent-insoluble pellet was dependent on the stage of oogenesis. In the mature oocyte when *bcd* transcripts remain in the egg cortex at the anterior end, all of these were bound to cytoskeleton elements, but after egg activation, most of the *bcd* RNA was recovered in the soluble fraction. Like the *bcd*, the *osk* transcripts also showed a dynamic association with cytoskeletal components during oogenesis.

Identification of the various proteins associated with the pellet and soluble fractions through Western blotting led Pokrywka and Stephenson[9] to conclude that microtubules, and not microfilaments, are required for the assorting of *bcd* RNA in the pellet fraction and the pellet fraction is enriched in components required for stable anchorage of *bcd* RNA rather than in elements required for initial localization events like transport or docking. It was also clear that the localization of *bcd* transcripts in nurse cells and in deeper cytoplasm of egg involves different mechanism than localization in the anterior cortex of mature oocyte, which alone was pellet-associated.

The *stau* protein has a very interesting role in localization of both *osk* and *bcd* RNAs at opposite ends of the egg. In the case of *osk* RNA, it has been known that the *stau* protein is associated with *osk* RNA to mediate its binding with cytoskeletal components that transport the complex to the posterior pole[10]. Other studies have shown that the plus ends of microtubules within the oocyte are polarized towards the posterior pole[11]. A visual demonstration of the posterior facing of the plus ends of microtubules in oocyte was provided by Clark *et al.*[12] in flies transformed with a chimeric gene having the kinesin domain on its 5′ end and the β-galactosidase coding region on the 3′ end: this fusion protein retains the properties of kinesin (moving along microtubules towards their plus ends) and also shows β-galactosidase activity, which can be cytochemically visualized as blue staining with the X-gal substrate. Since all the blue staining β-galactosidase activity was seen to move posteriorly (due to the kinesin domain) in oocytes of these flies, it was obvious that the microtubules in oocytes are highly polarized with their plus ends pointing posteriorly. Viewed in this context, it becomes clear that binding of the *stau* protein with *osk* transcripts facilitates attachment to microtubules for transport of the *osk* transcripts to the posterior pole. Once the *osk* transcripts are delivered at the posterior pole, the *stau* protein is freed and quickly recruited for *bcd* localization.

Ferrandon *et al.*[13] have very convincingly documented a mutual binding of the *stau* protein with the *bcd* RNA and the interaction of this complex with microtubules. These authors used an RNA injection assay to map the 3′ UTR of *bcd* RNA necessary for anterior localization and to visualize its specific interaction with the *stau* protein. *In vitro* transcribed *bcd* RNA (full-length mRNA or the 3′ UTR or variously mutated 3′ UTR) was microinjected at ectopic sites in 0 to 1 h-old embryos (the endogenous *bcd* transcripts at this stage are anteriorly localized), and following a brief chase, the embryos were fixed to immunologically monitor the distribution of *stau* protein: the normal *bcd* 3′ UTR rapidly recruited the *stau* protein around itself to result in microscopically visible aggregates which moved during cell cycle stages in microtubule-dependent manner. Using deletions and linker-scanning substitutions, three noncontiguous localization signals in stem III and distal regions of stems IV and V of the predicted secondary structure of the *bcd* 3′ UTR were identified. The *stau*-dependent localization of *bcd* RNA at the time of egg activation and its earlier *stau*-independent localization to anterior cortex of oocyte use different but overlapping sequence signals. Aggregation of the cellular *stau* protein in early embryos with the microinjected appropriate *bcd* 3′ UTR RNA and their movement with microtubules showed that the *bcd* transcripts and the *stau* protein are dependent on each other for complex formation and localization. It is interesting to note that during oogenesis the *bcd* transcripts and the *stau* protein do not recognize each other; at that time the *stau* protein is involved in localizing the *osk* transcripts. Only after delivering the *osk* transcripts at the posterior pole, does the *stau* protein quickly move to the anterior of egg and bind with the *bcd* RNA for its localization and anchorage at the anterior region. Since in both the oocyte and embryos the localization of the *stau* protein depends on the appropriate RNA (*osk* in oocyte and *bcd* in early embryos) and *vice versa*, Ferrandon *et al.*[13] suggest that perhaps the same microtubule motor is involved in both these transcript movements. However, the events that make the *stau* protein change its affinity from *osk* to *bcd* transcripts in the mature egg are not known. Also, if the *stau–bcd* complex has to move on the same microtubule motors as the *stau–osk* complex, a change in the microtubule polarity may be necessary.

The myelin basic protein mRNA when microinjected into mouse oligo-

dendrocytes also aggregates into large particles that are transported along microtubules in anterograde direction[14]. It is very likely that many more such examples will be known soon and a class of proteins will be identified that recognize the 'RNA zipcodes' and accordingly transport the RNA with the help of cytoskeletal components and deliver them at the specified destination. While microtubules may be principally involved in the transport, the actin filaments may have a greater role in anchoring the localized transcripts. Also, as in the case of *osk* and *bcd* transcript localizations during different stages of oogenesis, different subsets of cytoskeletal components may be involved in transport as well as anchorage of the same RNA in a stage-dependent manner. With the feasibility of doing sophisticated biochemistry and molecular probing *in situ* in the cell at light as well as electron microscopic levels, it should be possible in the near future to have full graphic details of the movement of specific transcripts in cells to their destination and their anchorage after delivery.

OPINION

Declining phase of quality research in our universities

Samir Bhattacharya

A ripple is taking the shape of a vigorous wave, we have ignored it for long and allowed it to grow, and were not careful enough about the power of its irreparable damage. I am talking about the declining phase of our university research environment. Everyone in the academic domain knows in what way the job of a university teacher differs from a college teacher. Teaching and research is obligatory to the university teacher while the latter is not so for a college teacher. To sustain and strengthen the academic environment in higher education, research activity is a must, as feedback from research will keep the standard of teaching high and the creativity of a teacher will encourage the students of higher education to develop their finer qualities. Although these are known, what we are witnessing in our country is the fast receding of such a notion in university education. Doubtlessly, it is the university to be blamed for this deterioration; more precisely, it is the university teachers. Everyone is pointing to the degeneration of research quality in our universities, but there is no serious effort as yet to recuperate the university from this situation. We have not so far been conscious enough about the fact that such a trend of low-quality research activity would destroy our university system, which is the primary productive centre of higher education. Masters degree is the essential passport for research career in any institution of this country.

Let us first see what could be the possible reasons for this situation. The present policy of merit promotion in the universities is a major factor, where quality is not the regulatory factor. A university teacher has to wait for a specific time period and her/his potentiality is then judged by the number of papers published and the number of Ph D's produced. Except for a few universities, in most of the universities the number of publications is one of the major criteria, not the quality of publications. This has resulted in the mushroom growth of private journals (published by a person), where peer review system does not operate and money is the prime objective. If one pays the publication charges, a paper will be immediately published. Such an easy way of increasing the number of publications and then claiming the promotion has two pronged injurious effects on the academic environment; (i) it substantially reduces the desire for quality research among the teachers and (ii) it dampens the spirit of a young incumbent in the university. One may presume it to be impossible as members of selection committee should definitely scrutinize the quality of publications. Unfortunately, this usually does not happen in the majority of universities even if the post is an open post. The system of selection sometimes includes allocation of marks for the number of publications and not for the quality of publication. A person who may have two high-quality publications in well-reputed international journals may not be selected against a person who has ten publications in unrefereed low-quality journals. Another harmful trend is the yield to local pressure by the university authorities where the presence of political milieu worsens the

situation. In such an atmosphere it is difficult to select a genuinely strong academic person with good research background; consequently, many a time the best person desiring to start a career in the university suffers from frustration. The cumulative result of all these is leading the universities towards a bad to worse situation. However, after entering the university as a lecturer or an assistant professor, a person finds that for promotion quality is not the criterion, quantity is the major thrust and therefore her/his attempt is to produce more papers in unrefereed, below-the standard journals and low-grade Ph D's. She or he will probably get more persons in support from the faculty than a person with the will of producing quality research. Thus, when more faculty members are on the other side, a real potential creative researcher does not find a congenial environment and of the two options, i.e. submitting to the other side or facing the odd environment throughout life, the former appears to be easier.

The total aspect has a snowball effect, the research students trained by these teachers will never look for quality research, they will rather waive the possibility of good research to dominate the situation. Recruitment is naturally being influenced by this faculty structure and by all chance one of the low-grade Ph D's will get the opportunity and such a person is expected to repeat the bad trend and this will go on. This is exactly what is happening today.

Another crucial drawback of the universities to create research environment is their poor infrastructural facilities. Universities are suffering from acute financial crisis. A major portion of their sanctioned money goes to salaries and wages, the remaining thin portion is not even enough to provide a reasonable infrastructure for teaching. Research assistance, therefore, is being kept at abeyance. At least a few university teachers who really want to do good research are not getting any support from the university. To them one of the criteria for the job appears to be meaningless: how can one pursue research in this age in such a poor infrastructural condition. Although they might have great potentialities, they are unable to fight this odd environment and ultimately submit to low-quality research to keep their promotion avenue open. In this way universities are losing capable and strong research workers, which is also a great loss to the country. One can argue that a person may develop infrastructural facilities through research projects from different national agencies. At the beginning of research career or without individual research contributions in a specific line, a grant to develop research facilities is rather difficult. The situation in the IITs and agricultural universities is somewhat different. One of my colleagues curtly replied to my above criticism by mentioning that after spending a huge grant on national laboratories, what is our return today. I have simply pointed out to him that one cannot improve his position by simply pointing out the fault of others.

However, what could be the steps to salvage universities from this degenerative stage. Everyone will feel the immediate necessity of such steps, not only to save our universities from the peril, but also to save the future of our nation. I have a few suggestions:

(1) It may be recalled that in the recent past the practice of the University Grants Commission to sanction university departmental posts and necessary financial assistance was to evaluate the academic progress (which included both teaching and research curricula) of the department by means of a visiting committee, followed by the recommendation of this committee. This practice has been stopped for long. It is high time to invoke this practice again as evaluation of academic performance will compel the departments to improve their quality. This will provide an incentive to research since the committee may recommend open posts on certain subjects as per the performance.

(2) In the open posts, weightage should be given to the capability of a person instead of time-bound experience.

(3) There should be a ban on giving credit for publication in unrefereed journals.

(4) Assessment of the number of Ph D's produced by a teacher should be based on the publications from a particular thesis in refereed journals.

(5) The scope of Ph D registration by a part-time student (without any research fellowship) should be very limited as this category is now a major source in increasing the number of Ph D's of a university teacher. Part time Ph D registered students are usually not very much inclined to do quality research, their objective being just to get a degree, and university teachers, on the other hand, get an easy community to increase the number of Ph D's produced by them.

(6) Both for recruitment and promotion, citation index of publications should be given prime importance; this will enable recruitment and promotion of the best person among the applicants. Moreover, it will waive the present trend of publication in unrefereed journals; these journals are not indexed.

(7) Steps should be taken to provide infrastructural facilities for research activities.

(8) There should be an effective interaction between the university teachers and the research scientists of the national laboratories funded by CSIR, DST, DBT, ICMR, ICAR, etc. This will be mutually beneficial for university teachers and research scientists of national laboratories so far as the creativity part of research is concerned. Moreover, university teachers will be able to utilize the research facilities of national laboratories and scientists from those institutes may also take part in teaching as this will not only benefit the students but also provide the opportunity to the scientists to have exchange with bright students of the universities. Such an interaction is not difficult in the metropolitan cities, while building of national laboratories nearer to the non-metropolitan university premises may cause enormous gain to both research and teaching.

There may be other suggestions, the supreme duty for all of us being not to stand as passive onlookers to the deterioration of research activity in our universities. It is already affecting the teaching adversely and will soon take the shape of an incurable chronic disease which will destroy the future of our higher-education system, the worst sufferers being our future young generations. A day will come when a Master's degree holder in science will speak in a different language which will not be communicable to the advanced arena of science, and higher degree from the university will completely lose its credibility. Still there is time and hope, and steps to resuscitate the universities should be initiated immediately.

Implications of recent levelling observations for Tehri and other high dams in the Himalaya

Seismic hazards around the Tehri and other existing and proposed high dams in the Himalaya are a matter of concern to many people. The magnitude and dimensions of the problem appear to increase with every new set of geophysical and geological data gathered from the Himalaya. But the flexibility and readiness of the people involved to improve their designs for the dams transparently in the light of the evolving perceptions about seismic hazards[1–5] is not evident to us at least. Still, we buttress further in this article the evidence for an aspect of seismic hazards in the Himalaya.

A set of repeat geodetic levelling observations[6] obtained in Nepal (Figure 1 and 2 *a*) during the last two decades vividly reveal the ongoing deformation of the Himalayan upper crustal rocks in response to the relative convergence of Indian and Eurasian lithospheric plates. Laterally localized near-surface deformation is superimposed on broader-scale crustal strains (Figure 2). We provide here an explanation for some of the more localized elevation changes observed in Nepal and consider their seismic hazard implications.

The Nepal levelling data

Jackson and Bilham[6] have recently published the results of two successive sets of levelling observations across the width of Nepal along the main north south highway through Kathmandu (Figure 1). The period elapsed between the two sets varied between 2 and 13 years. Figure 2 *a* is a display of the observed annual rates of elevation changes along a line normal to the local trend of the Himalaya. Figure 2 *a* is created by projecting the benchmark positions along the winding highway onto a horizontal straight line oriented along N 10°. Jackson and Bilham[6] have provided an interpretation of the relatively longer wavelength features of the curve displayed in Figure 2 *a* by postulating a slip rate of 5 mm/yr on the detachment (Figure 2 *c*), an intracrustal thrust fault type of surface of separation between the Himalayan rocks above and the relatively northward-moving Indian shield material below[7].

Data from only the southern Nepal are shown in Figure 2 *a* for three reasons. Firstly, distance-dependent random errors in levelling observations grow northward from the southern end of the levelling line[6]. Secondly, as the levelling line approaches the main central thrust (MCT), the effect of plate convergence accommodated along a major ramp in the detachment becomes prominent in the form of a large-amplitude, long-wavelength signal in the elevation change observations[6]. This is not of interest in the present context. Thirdly, most of the river valley projects and high dams that can be envisaged to develop the hydroelectric and irrigation potential of these hills are located in the Lesser and Outer Himalaya.

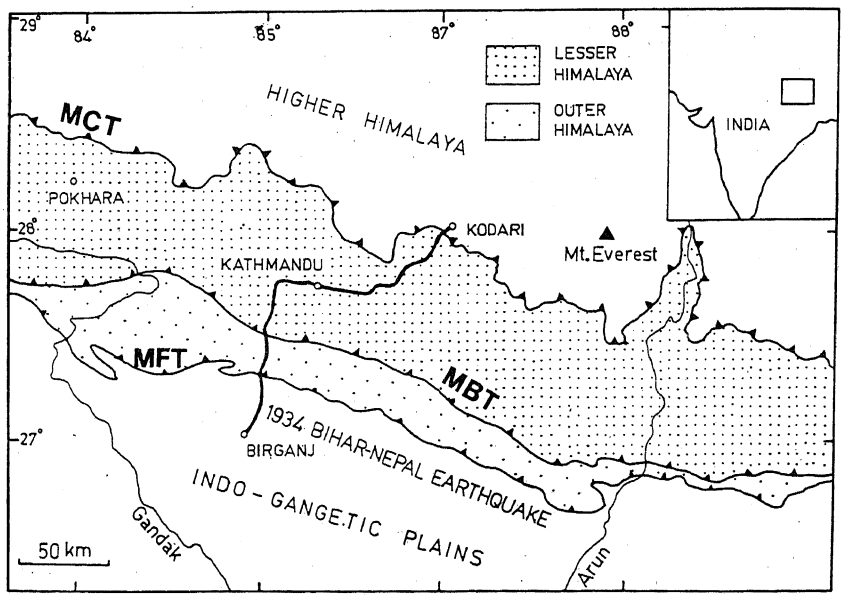

Figure 1. Location of the levelling line in Nepal. MFT – main frontal thrust; MBT – main boundary thrust; MCT – main central thrust.

Imbricate thrusts in the Nepal Himalaya

Several shorter-wavelength signals in the Nepalese levelling data deserve explanation also. We show in Figure 2 *c* our interpretation of the two most prominent of these features on the assumption that they could be associated with slip on relatively steeper near-surface thrust faults. Similar faults could be conceived for other less prominent short-wavelength features in the data. Such shallow-level and relatively steep dipping thrust faults are called imbricate thrust[8]. They occur in suites and are associated with a major, deeper thrust fault dipping at a comparatively gentler angle[8]. Although geological mapping in different parts of the Himalaya is still far from complete, numerous imbricate thrust faults have been mapped already[9, 10]. Since precise locations of benchmarks used by Jackson and Bilham[6] have been masked, it is not possible to associate the imbricate thrusts postulated by us in Figure 2 *c* with specific thrust faults mapped in the Nepal Himalaya. The possibility also exists that the geodetic observations may have revealed imbricate thrusts which are as yet 'blind' or concealed below the ground surface.

Role of imbricate thrusts during a great thrust earthquake

Since the observations reported in Figure 2 *a* were taken during a period when no major earthquake had occurred in the region, they reveal aseismic crustal defor-

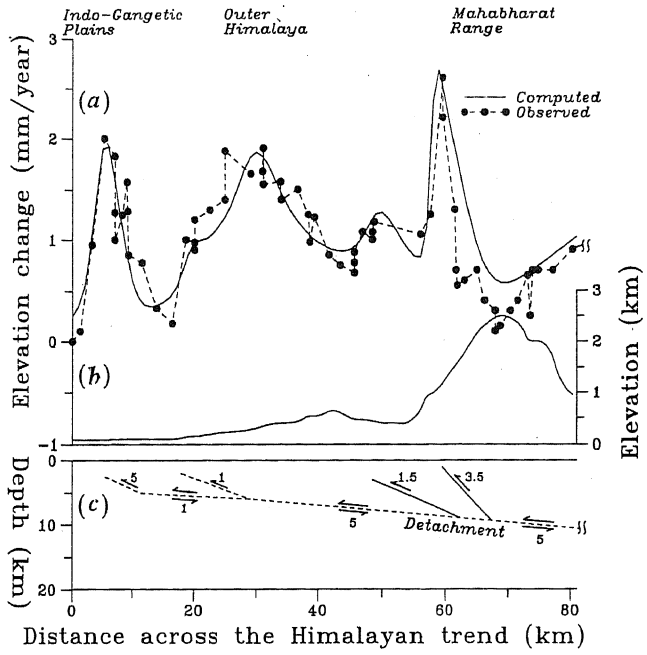

Figure 2. ***a***, Comparison of observed and calculated rates of ground elevation changes in southern Nepal. ***b***, Profile of topography along the projected line. ***c***, The model used to compute the results shown in (***a***). The dotted parts of the fault model were also considered by Jackson and Bilham[6] to explain the long-wavelength features. Solid lines indicate the imbricate faults suggested by us to explain two short-wavelength features in the observations. The numerals shown against faults represent the postulated annual slip rates (mm/yr) on the respective faults to explain the observations.

mation. It is not unreasonable to surmise that these imbricate thrusts will be reactivated also in the next great earthquake of the region. These faults could be loci of large relative slips between rocks across them. Significant ground level changes may occur in regions near their updip terminations. Concomitant high particle velocities and accelerations may be expected in these pockets during great earthquakes. Ample evidence of this has been documented in the literature.

Oldham[11] surveyed the changes in the ground surface brought about in the Shillong plateau region during the great earthquake of 12 June 1897. He reported surface-breaking faults near the northern border of the Shillong plateau. He estimated relative ground level changes of up to about 12 m near these faults. Although Oldham[11] estimated that the faults were subvertical, Gahalaut and Chander[12] have surmised that they could be imbricate to the major mid-crustal thrust fault in which the main rupture of this earthquake occurred. The 1897 earthquake caused the ponding of south-flowing rivers in the southern part of the Shillong plateau[11]. This too could be explained with coseismic activity on imbricate thrust faults under southern Shillong plateau[12]. Finally, Oldham[11] argued lucidly from the evidence of boulders thrown into air during the earthquake that ground acceleration exceeding g (acceleration due to gravity) occurred during that earthquake. We suggest that slip on a nearby imbricate thrust was involved in this case also. It is important to recall that Oldham[11] has given exactly the same explanation for these observations. However, he used the phrase 'secondary and tertiary reverse faults' instead of 'imbricate thrust faults'. The hazard implication of this observation of high acceleration has been remarked by Khattri[2] also.

Byrne *et al.*[13] investigated the source of the 1945 Makran earthquake and suggested that prominent uplift along a narrow coastal belt could be due to slip on a shallow fault imbricate to the deeper detachment-type plate boundary in the Makran subduction zone. Barrientos and Ward[14] and Plafker[15] also referred to significant activity on imbricate thrusts extending up from the main plate boundary thrust faults associated with the great Chile earthquake of 1960 and the great Alaska earthquake of 1964.

Implication of imbricate thrusts for civil engineering structures in the Himalaya – the concept of the nearest active fault

An important consideration for the design of a critical civil engineering structure, such as a dam or a nuclear reactor, especially from the standpoint of seismic hazards, is the distance of the site from the nearest active fault. Ordinarily, the distance between an engineering site and a surface-breaking active fault is determined on a geological map. However geodetic and other geophysical techniques, such as earthquake observations, can lead to identification of subsurface active faults also. Geodetic techniques have the advantage that even aseismically active faults can be detected.

Recent investigations of great Himalayan earthquakes have led to the consensus that they occur by extended ruptures in the detachment[7, 12, 16–20]. The depth of the detachment has been estimated to be less than 5 km under the main frontal thrust (MFT) and about 17 km under the MCT[7, 16, 18, 19, 21–23]. Thus, there is at least one active fault beneath every engineering site in the Outer and Lesser Himalaya. If some faults imbricate to the detachment could be active in this Himalayan domain, as has been remarked elsewhere on geological grounds[1, 10, 24–26] and shown to be the case in the Nepal Himalaya through geodetic observations, then they could be potentially even nearer to an engineering site than the detachment.

On the Tehri dam site

The Kumaun–Garhwal Himalaya, including the region around Tehri dam site in Garhwal (Figure 3), has been investigated geologically, especially in the recent decades. The monograph by Valdiya[10] is an important source book for the geology of the Lesser Himalaya of the Kumaun–Garhwal region. Valdiya[1, 10, 24–29] and others[30–32] have documented geomorphic and other geological evidence for neotectonic and even continuing tectonic deformation in different longitudinal and transverse segments of the Kumaun–Garhwal Himalaya. This includes suggestions about possible deformation along imbricate thrusts. See the discussion section below for a limitation of the geologi-

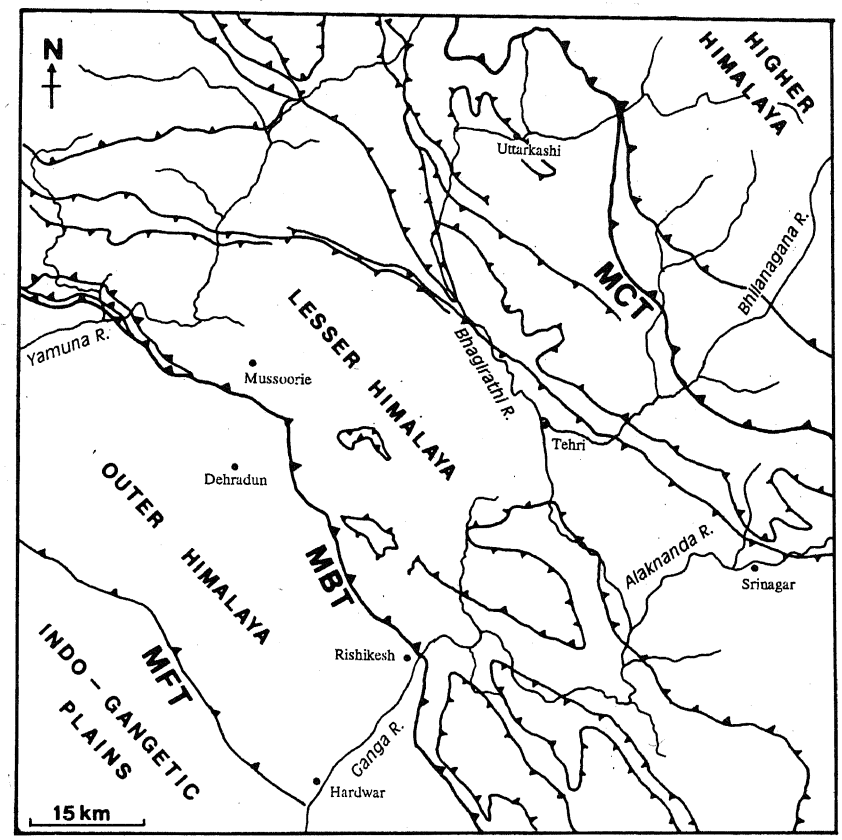

Figure 3. A randomly selected geological map of a section of the Lesser Himalaya showing some of the mapped thrust faults (after Valdiya[10]). Smaller unnamed faults hading northerly are imbricate faults.

cal inference regarding the activity of faults.

The 1991 Uttarkashi earthquake[33] and recent seismicity observations[34–35] provide further confirmation about the active or ongoing tectonics of the Garhwal region. There was damage at Tehri during the great Kangra earthquake of 1905 (ref. 36). The rupture models proposed by Seeber and Armbruster[7], Chander[19] and Gahalaut and Chander[16] suggest that the detachment under the NW Garhwal Lesser and Outer Himalaya slipped during the earthquake. Epicentres of many small and microearthquakes have been located within about 10 km of the Tehri dam site through observations made[34, 35] in the 1980s. Composite fault plane solutions for some of these earthquakes suggest activity along high-angle reverse faults within the upper 15 km of the crust[34, 35]. These seismologically inferred reverse faults too could be properly called imbricate thrusts. However, in the absence of sufficiently detailed geological mapping as well as the inevitable uncertainties in the estimates of hypocentral coordinates it is not possible to associate these seismologically inferred imbricate thrusts with specific geologically mapped faults of the region. Still in our opinion this is an evidence showing that at least some imbricate thrusts are active today close to the Tehri dam site.

Detailed designs for Tehri dam and appurtenant structures have been made already. Still we suggest that, in view of the magnitude and importance of the project, detailed repeat geodetic observations should be undertaken around the Tehri dam site to supplement the geological and seismological observations and to detect if in addition any buried or exposed faults near this site also are currently creeping aseismically as in the Nepal Himalaya. If such observations have been taken already by governmental agencies, then the results should be published so that interested scientists outside these agencies, may also assess them. The published levelling observations for the Saharanpur–Dehradun–Mussoorie highway[36, 37] are not relevant for this purpose because of the distance between the site and the closest benchmark.

Discussion

Bomford[38] in his well-known book on geodesy specifically recognized that geodetic surveys are useful at civil engineering sites to mark points on the ground with great accuracy. Bomford[38] also underlined the use of repeat geodetic observations for crustal deformation studies. Our analysis above illustrates the application of geodetic observations for identifying the locales of ongoing crustal deformation in the Himalayan setting specifically. Combining the results of sufficiently detailed geodetic observations with the geological and seismological observations should help in settling the question of the nearest active faults for various dam sites with greater confidence.

The main advantage of geodetic methods is that we can detect activity which has occurred during the period between successive occupations of the benchmarks. The geological procedures, on the other hand, indicate activity without being very specific about their dates except when geochronological evidence regarding the activity is forthcoming. Geodetic observations should complement seismicity observations by identifying currently active faults.

We recall here that geodetic observations have been collected in India for nearly two centuries[39]. But only a very small subset of these are repeat observations with a possible bearing on crustal movements in respective regions. There are three prime requirements when geodetic observations are to be used in this way. Firstly, the benchmarks should be closely spaced. Secondly, the reference benchmark should be well outside the region of suspected crustal deformation. Thirdly, the reoccupation of benchmarks should be at sufficiently short intervals of time. To the best of our knowledge there are no repeat geodetic observations in India which fit these requirements entirely. Repeat geodetic observations in connection with the 1897 Shillong plateau[11] and the 1934 Bihar–Nepal[40] earthquakes suffer from the fact that they were within or close to the epicentral tracts. Repeat levelling along the Saharanpur–Dehradun–Mussoorie line has revealed[36, 37] changes during and sub-

sequent to the Kangra earthquake of 1905. But the large distances between benchmarks, the long time gaps between successive observations and the desirability of shifting the reference benchmark at Saharanpur to a bed rock site further south have been remarked[41]. Finally, repeat geodetic observations to measure aseismic fault movements in the Hardwar[42], Kangra[43] and Mandi[44] regions had too limited a spatial extent in our opinion.

An important reason why geodetic methods have not been employed widely for dam site investigations is that in the past the procedures were slow and relatively costly. However, with the availability of the global positioning system these factors should no longer be disadvantages or deterrents for carrying out geodetic surveys as envisaged.

Conclusion

Our interpretation of recent levelling observations in the Nepal Himalaya suggests that a part of the current interseismic upper crustal deformation may be localized along shallow imbricate thrust faults. We have emphasized three implications of these geodetic observations and analyses. Firstly, similar imbricate faults may be slipping aseismically elsewhere in the Himalaya also. Secondly, during great earthquakes of the respective regions, coseismic slip along such faults may lead to locally strong ground motion with attendant large displacements and high accelerations. This could be a threat to nearby civil engineering structures, such as dams, as well as smaller, non-engineered constructions, such as individual houses in villages. Thirdly, there is need to expand repeat geodetic observations in all Indian segments of the Himalaya.

Storing river runoff in the Gulf of Khambhat: A critique of the 'Kalpasar' concept

A scheme of dam construction across the Gulf of Khambhat (Cambay) for storage of runoff water of several rivers draining into the Gulf has been proposed by Kane[1]. The proposed dam will connect Gundi near Bhavnagar on the west (Saurashtra side) and Hansot near Bharuch on the east (South Gujarat side) and is expected to create a 2900 km^2 freshwater lake. The total length of the dam is estimated to be 56.4 km and the cost approximately Rs 3000–4000 crores (~US$ 1000 million). The proposed lake has been named 'Kalpasar' (taken from a Sanskrit word meaning a lake which can give one whatever one wishes standing on its bank). The annual river inflow into the Kalpasar lake has been estimated to be about 14,000 million m^3 after the proposed Narmada dam and other irrigation schemes on the rivers Sabarmati, Mahi and other minor rivers have been completed.

M/s Haskoning, a Dutch firm, was retained by the Government of Gujarat and a reconnaissance report on this project was submitted in 1989. The proposal of Kane[1] is based on the report of Haskoning[2]. The scheme has also been advocated by Patel[3] as part of a larger strategy to develop water resources in the State of Gujarat.

While we generally endorse the concept of creating a freshwater lake in the Gulf of Khambhat, we suggest an innovative modification of the dam structure that may help to store more fresh water and additionally lead to considerable saving in the cost through reduction in both length and thickness of the dam structure. The proposed modification is based on the basic hydrological principle, namely, the significant density difference between the sea water and the river runoff, that should allow the lighter river water (density ~1.0 g/cc) to float on the denser sea water (density 1.025 g/cc). Employing this principle, if the dam structure is so designed that it is open from the bottom allowing hydraulic continuity on north and south of the dam, one should expect the incoming lighter river water to push the denser sea water out to the open ocean through the open bottom of the dam. The modification may also obviate some of the difficulties that we anticipate in the scheme as described by Kane[1], without affecting the possible benefits.

In the scheme proposed by Kane[1] an earth fill dam is to be constructed across the Gulf along a suitably selected contour so that the maximum depth of the water column does not exceed 30 m. At the time of the lowest tide level, sea water from the northern (landward) portion of the dam is to be drained out to the southern (seaward) side, to the extent possible through sluice gates. Subsequently, when the fresh water in the monsoon starts flowing into the northern portion through the rivers, this portion is expected to be converted into a freshwater lake through mixing and dilution of the remaining sea water with the in-flowing river water. In this manner after a period of a few (3–5) years the reservoir is expected to be washed off of all the residual sea water. In this scheme, the maximum water that can be stored in the Kalpasar without flooding any additional coastal areas is between the highest and the lowest tide levels. With an average of 14,000 million m^3 of water per annum, estimated to be available in the 2900 km^2 area of the lake, the maximum estimated thickness of freshwater column at the dam site is expected to be in excess of 6 m, which is of the same order as the tidal range (about 8 m) in the Gulf of Khambhat. Thus, even though a very large volume of reservoir will be created (up to 30 m depth at the dam site), the volume actually available for storage of fresh water would be smaller than the estimated freshwater inflow in several years of above-average rainfall. Therefore, the excess river water runoff would have to be either stored on land above the high tide level or would have to be let out into the open sea.

There is also some concern regarding mixing and dilution being able to wash off the residual sea water in 3–5 years time as envisaged by Haskoning[2] and Kane[1]. Simple calculations assuming the water body to be wedge-shaped between the northernmost section of the Gulf (~100 km from the dam) and the dam site, where the depth will be ~30 m, give a residence time of water in the lake (ratio of the total storage volume to the annual average inflow) of about 5 years. But for salt concentration to reduce from the sea water value of ~35,000 ppm to ~500 ppm (suitable for irrigation and drinking), the time required will be much longer even if perfect mixing and no evaporation (about 2 m water column) are assumed. Mixing and dilution, therefore, may not result in Kalpasar becoming a freshwater lake in a reasonable period after construction of the dam.

However, if we could construct the dam in such a way that the bottom 10 m or more is open over a fairly large length of the dam, say where the water column is more than 20 m, we may be able to obviate the above difficulty without compromising in any way the expected benefits. With the bottom of the dam open, there is no need to have gates to empty the reservoir. Also there is no need for having any spillway for draining off the excess river inflow out of the reservoir into the sea. Both these functions, namely (i) the draining of the sea water and (ii) any excess river inflow, will automatically be accomplished through the lower open end of the dam wall due to the transfer of the underlying sea water, governed by the hydrostatic balance on the two sides across the dam. The maximum height of the dam above the mean sea level in our scheme needs to be just enough to prevent the ingress of sea water overflowing the dam resulting from tide/wave-induced changes in the sea level.

The density contrast between the river runoff and the sea water is envisaged to maintain a reasonably well-defined interface at a depth of about 6 m or more to enable exploitation of the stored fresh water in a meaningful manner. This interface is, however, not static but moves up and down in response to hydrostatic changes induced (i) on the seaward side by the tides and waves and (ii) on the reservoir side by the inflow/consumptive use of the runoff water. Therefore, it may not be unreasonable to apprehend that due to mixing the interface may not be well defined, thereby defeating the very purpose of creating the reservoir at a huge expense. This is an aspect which

needs careful investigation employing both mathematical and physical models. However, a positive aspect of our scheme is that all inflows of fresh water into the reservoir not consumptively utilized will cumulatively depress the interface on the reservoir side and increase freshwater storage. Such inputs of fresh water to the Kalpasar lake also include rain (about 0.7 m) falling directly on to the lake and inflows from the minor rivulets, streams, creeks and channels and ground water discharge not accounted for in the 14,000 million m^3 of runoff from major rivers after the proposed dams on the Narmada and other rivers have been completed. We, therefore, intuitively anticipate that this effect involving cumulative lowering of the interface (with no spillage) will more than compensate for the possible mixing of saline and fresh water due to vertical movement of the interface induced by tides/waves. We expect that pressure changes due to the tides and waves can be expected to be communicated from the open sea side to the reservoir side, through the open bottom, rather gently in a piston-flow-like manner due to the damping of the disturbance with depth in the 20 m or more water column on either side of the dam. The dam itself will prevent the transfer of the wave/tide-induced turbulence at the surface from the open sea to the reservoir side.

The other factors influencing the position and thickness as well as movement of the fresh-water–sea-water interface in the reservoir, such as evaporation, consumptive use of water, wind-induced waves in the reservoir itself and the tidal effects within the body of the water stored in the reservoir, are common to both the schemes and, therefore, are not being discussed here. In our view, mixing is an area of major concern that needs a detailed investigation through mathematical models of currents and mixing processes likely to operate in the Kalpasar lake and the extent to which they may affect adversely the quality of water stored in the lake.

In situ preserved *Vertebraria* axes in Ib River Coalfield, Orissa

The Permian Gondwana form genus *Vertebraria Royle*[1] occurring from Post-glacial time through Late Permian is characterized by elongate, flattened, segmented, cylindrical casts which are simple or branched, often bearing root-like organs at the transverse ridges. In transverse section the *Vertebraria* axes show wedge-like sectors radiating from the centre[2]. According to Mussa[3] *Vertebraria* is a complex form consisting of several genera. Specimens of *Vertebraria* are found preserved in positions both parallel and perpendicular to the bedding plane and the actual nature of these axes was quite controversial for some time[3–9]. Most of the specimens assigned to *Vertebraria* are generally impressions or compressions and very rarely petrified specimens with anatomical details. It consists of a central region of exarch primary xylem with four to seven radiating arms of secondary xylem. The distinct growth rings with septate arrangement is surrounded by a cylindrical periderm with a well-developed cork, leaving spaces between the xylem arms. In longitudinal section the secondary xylem arms are connected at varying intervals by transverse platforms, also composed of secondary xylem tracheids, but generally containing a root trace.

Several specimens of *Vertebraria indica* Royle were collected from the Barakar beds exposed in a nala near Ganga Nagar village near Brijraj Nagar town, District Sambalpur, Orissa. No other element of Glossopteris flora is preserved in this bed. Some 50 specimens were found preserved as casts in the fine-grained, light pink, hard shales in an area of 2–3 m. The surface view showed 5–6 wedges 0.5–2.0 cm in diameter, with very little pith in the centre. The maximum length of these axes was 8.4 cm, lying diagonally along the bedding plane. Growth directions of these axes in the sediment indicate that *Vertebraria* was an underground root system of some plant. The actual plant which bore these underground axes was perhaps drifted to another site. Diagonal and vertical axes (Figure 1 *a, b*), preserved in a small area of 2–3 m, probably belonged to a single plant and represent *in situ* preservation. Total absence of horizontal axes and any other plant parts led us to believe this. The presence of such axes in various coal fields[10–14] indicates that some of the species of *Glossopteris* had arborescent habit supported by a well-developed strong root system. Wherever such vertical and diagonal axes were found, other plant organs like leaves were not found in nearby areas. Though horizontal axes along with other plant parts are commonly found in most coalfields, indicating autochthonous nature of coal, in no way are such vertical and diagonal *Vertebraria* axes indicative of autochthonous nature of coal as believed by some. Enormous quantity of vegetal matter which might

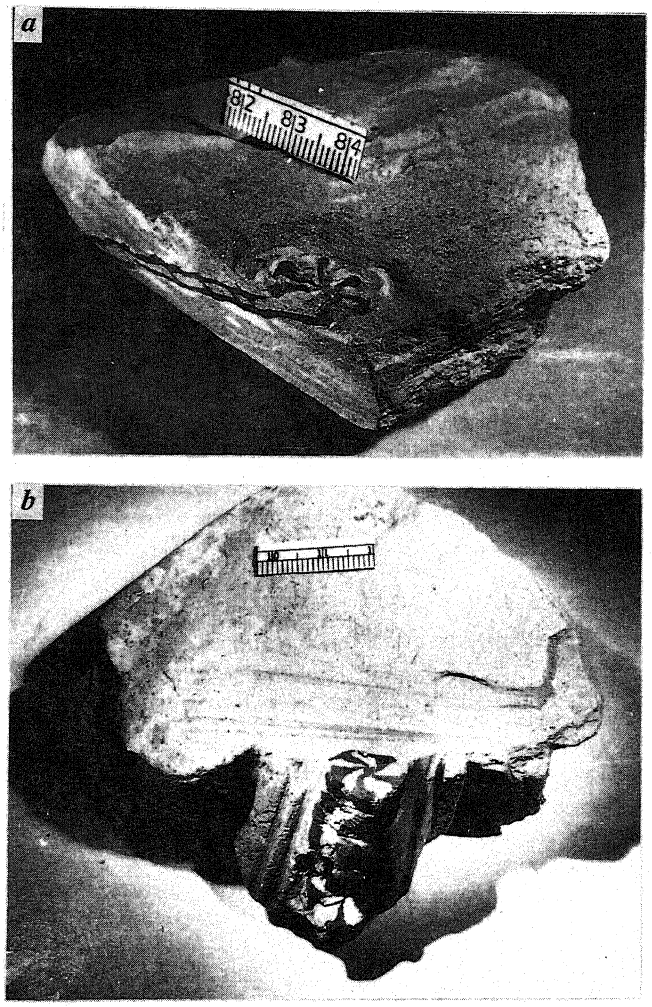

Figure 1 *a* **and** *b*. *Vertebraria indica* Royle, longitudinal sections of the specimens to show diagonally and vertically penetrating axes in the sediments, respectively. B.S.I.P. Museum specimen numbers 36863 & 36864.

have been required for peat formation of Gondwana coals cannot be sufficiently provided by few *in situ* preserved plants and their root system. It is logical to think that root system already embedded in the palaeosols had better chances of getting preserved *in situ* than other plant parts as found in Ib river and other coalfields of Lower Gondwana of India.

Role of phospholipase C in the cryptobiotic cysts of the fairy shrimp *Streptocephalus dichotomus*

As our earlier report[1] disclosed the occurrence and functional significance of the enzyme PC-PLC (phosphatidylcholine cholinephosphohydrolase) in the cryptobiotic cysts of the fairy shrimp *Streptocephalus dichotomus*, the involvement of biological catalysts (enzymes) in the hydration-dependent hatching of the cysts becomes quite evident.

Ever since the introduction of term 'cryptobiosis' in biology by Keilin[2], it has fascinated many investigators due to its unique features like maintenance of embryonic viability during thermal stress and the ability to withstand dehydration. *S. dichotomus*, which inhabits the freshwater ponds, undergoes cryptobiosis during dry summer period in order to overcome the adverse conditions. Though a detailed study on the egg morphology[3], biochemistry[4] and reproductive biology[5]

has been carried out, the role of enzymes involved in signal transduction has not yet been investigated in detail.

Although PI-PLC (phosphatidylinositol phosphodiesterase) has been studied extensively in mammals and micro-organisms[6], reports on the role of its substrate, namely phosphoinositides, are available only in the embryonic development of sea urchins[7]. As a growing body of evidences disclose the significance of inositol phospholipids[8] and their hydrolytic products like DAG[8] in the transduction of signals from external to internal cellular system, the role of PI-PLC becomes seldom negligible.

As cyst hatching involves hydration for a definitive period (24 h), presumably some signal is transduced through messenger molecules. This, and the earlier results which revealed the role of calcium[9], $pH_{(i)}$ (ref. 10) and PC-PLC[1] initiated studies on whether or not the PI-PLC has any role in cyst hatching. Cysts were collected from the animals as described previously[1], homogenized in Tris–acetate buffer (0.01 m, pH 7.5) and centrifuged at $4500 \times g$ for 20 min in a KUBOTA-1500 refrigerated centrifuge. The supernatant was decanted and the pellet was redissolved in the same buffer and centrifuged as above. Both the supernatants were pooled up and used as the sample for the assay.

Activity assay of PI-PLC was carried out by the alkaline phosphatase releasing method as described by Ikezawa and Taguchi[11]. In brief, male rat (Albino, Wistar strain) kidneys were excised and homogenized in ice-cold 0.25 M sucrose solution. To the homogenate 0.5 ml of the sample was added and incubated at 37°C for 30 min. After the incubation, 1 ml aliquot was withdrawn, cooled in an ice bath and then centrifuged at $1,09,000 \times g$ for 90 min in a Beckman L7-65 ultracentrifuge. The supernatant represented the cytosolic fraction and the sediment the particulate fraction. Both cytosolic and particulate fractions were assayed for the alkaline phosphatase activity according to Engstrom[12]. The absorbance was recorded at UV–visible 160 Å spectrophotometer.

Figure 1 depicts the activity assay results of PI-PLC at different hours of hydration of the cysts of *S. dichotomus*. The enzyme activity of the cytosolic fraction increased in the first 12 h of hydration (0–12 h), followed by a subsequent decrease in the next 12 h (12–24 h) of hydration, whereas in the particulate fraction the activity of the enzyme decreased initially (0–12 h) and increased in the next 12 h (12–24 h) of hydration. Although in both cytosolic and particulate fractions the activity of the enzyme varied considerably between the first 12 h (0–12 h) and the next 12 h (12–24 h), a unique feature observed is that the activity in cytosolic fraction is inversely proportional to particulate fraction. In other words, whenever there is an increase/decrease in the PI-PLC activity of the cytosolic fraction, it is inversely proportional to the particulate fraction.

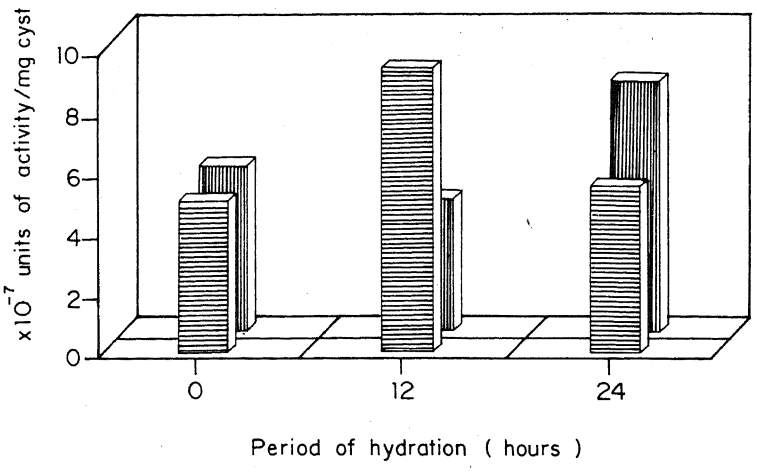

Figure 1. PI-PLC activity in the cryptobiotic cysts of the fairy shrimp Streptocephalus dichotomus. ▤, Cytosolic fraction; ▥, Particulate fraction.

Unlike PC-PLC, where there is a steady-state increase in the activity up to the period of hatching[1] (i.e. 24 h), PI-PLC has a fluctuating trend. As PI-PLC is a membrane-bound enzyme, it is presumable that the activity is high in the particulate fraction than in the cytosolic fraction at 0 h of hydration. The increase in activity in the cytosolic fraction at 12 h of hydration can presumably be accounted for its transmembrane mobility as it has to hydrolyse the cytosolic IP. Similarly, the decrease in activity in the cytosol at 12–24 h of hydration implies the culmination of PI-PLC-catalysed reaction.

From the present report it is evident that a change (increase/decrease) in the activity of PI-PLC does occur in both cytosolic and particulate fractions pertaining to the period of hydration.

Reflecting diffusions*

S. Ramasubramanian

Probabilistic models of diffusion processes with 'reflecting boundary conditions' are discussed; the domains considered can be nonsmooth.

THE phenomenon of diffusion in free space (in a dilute solution) can be modelled in a mathematically rigorous fashion by probabilistic methods; in fact, this has been one of the major achievements of probability theory. This has led to a very fruitful interaction between the theory of partial differential equations and the theory of Markov processes; the interface is now known among probabilists as the theory of diffusion processes[1–5].

The aim of this exposition is to indicate how probabilistic methods are applied to model diffusions with 'reflecting boundary conditions'. To keep the length of the article within reasonable limits, we do not consider asymptotic properties, connections with boundary value problems, etc. And for the same reason it is inevitable that we indulge in a bit of probabilistic jargon without explanation; see refs 1, 3, 6–8 for more information concerning unexplained technical terms like submartingales, Markov property, stochastic integrals, . . .

Diffusions in $\mathbb{R}^d$

We now briefly review three ways of modelling diffusion processes in $\mathbb{R}^d$. This will help the reader appreciate the approaches taken later to study reflecting diffusions. Our notation will also get fixed in the process.

Let the operator A be defined by

$$Af(x) = \frac{1}{2}\sum_{i,j=1}^{d} a_{ij}(x)\frac{\partial^2 f(x)}{\partial x_i \partial x_j} + \sum_{i=1}^{d} b_i(x)\frac{\partial f(x)}{\partial x_i}, \qquad (1)$$

where the coefficients a_{ij}, b_i are sufficiently smooth real-valued functions on $\mathbb{R}^d$; A is assumed to be uniformly elliptic; $b(\cdot)$ is the *infinitesimal drift* and $a(\cdot)$ the *infinitesimal dispersion.*

Semigroup approach

Let $p(s, x; t, z)$, $0 \le s < t$, $x, z \in \mathbb{R}^d$ denote the (minimal) fundamental solution for the *Fokker–Planck equation*

$$\frac{\partial u}{\partial t}(t, z) = A_z^* u(t, z), \quad t > 0, \quad z \in \mathbb{R}^d, \qquad (2)$$

where A^* is the formal adjoint of A, and the subscript z denotes differentiation in the z variables; that is, if the initial value $u(0, \cdot) = f(\cdot)$ is specified then u can be given by

$$u(t, z) \equiv (T_t^* f)(z) = \int_{\mathbb{R}^d} f(x)p(0, x; t, z)\,dx. \qquad (3)$$

Since the concentration of a diffusing species satisfies the Fokker–Planck equation, knowledge of p determines the system completely once the initial concentration is known.

It can be shown that $p(s, x; t, \cdot)$ is a probability density function, satisfies the so-called Chapman–Kolmogorov equation, etc.; in other words, p is a transition probability density function (in the sense that $p(s, x; t, z)\,dz$ gives the probability that a diffusing particle starting from x at time s reaches a sufficiently small neighbourhood of z at time t). Hence, by the theory of Markov processes, there is a continuous-time Markov process in $\mathbb{R}^d$ with continuous sample paths for which p is the transition density. This process can be called *diffusion with generator A*. As p satisfies the Chapman–Kolmogorov equation, $\{T_t^* : t \ge 0\}$ given by eq. (3) forms a semigroup of operators. This is the classical approach to diffusions, pioneered by Kolomogorov and Feller, and depends on PDE theory for the guaranteed existence of the fundamental solution.

If $a(\cdot) \equiv (d \times d)$ identity matrix, $b(\cdot) \equiv 0$, then $A = (1/2)\Delta = A^*$, eq. (2) is the heat equation, p is the heat kernel and the corresponding diffusion is, of course, the standard Brownian motion (this explains the fondness for the factor 1/2 in eq. (1) among probabilists!). This has been the prototype of diffusion and corresponds to the motion of a diffusing particle purely due to fluctuations caused by bombardment by solvent particles in the absence of external forces, friction, etc.[8].

SDE approach

Levy had suggested that the motion of a diffusing particle can be represented, in differential form, by

$$dY(t) = \sigma(Y(t))dB(t) + b(Y(t))\,dt, \qquad (4)$$

S. Ramasubramanian is in the Indian Statistical Institute, 8th Mile, Mysore Road, Bangalore 560 059, India.

*This is a slightly enlarged verion of a lecture given at the Department of Mathematics, Indian Institute of Science, Bangalore on 10 February 1995.

where $\sigma(x)$ is a matrix such that $\sigma(x)\sigma^*(x) = a(x)$, $\{B(t): t \geq 0\}$ is a standard d-dimensional Brownian motion. The idea is: in a short interval of time the diffusing particle behaves locally as a Brownian particle with appropriate 'standard deviation' σ subject to an 'infinitesimal drift' b. However, it is well known that the Brownian trajectories are nowhere differentiable. It has been a seminal achievement of K. Ito to give meaning for integrals of the form $\int f(s, \omega)\, dB(s, \omega)$ for a large class of processes f; such integrals are called Ito integrals. Then the formal differential expression (4) can be interpreted as the stochastic integral equation

$$Y(t) = Y(0) + \int_0^t \sigma(Y(s))\, dB(s) + \int_0^t b(Y(s))\, ds. \qquad (5)$$

When σ, b are Lipschitz-continuous and satisfy certain growth conditions, it was shown by Ito (essentially by Picard's iteration) that eq. (5) has a unique solution $Y(\cdot)$; also the solution Y is a continuous Markov process. If Y has a sufficiently smooth transition density p, then it can be proved that p is the minimal fundamental solution for eq. (2). Thus, the solution of the *stochastic differential equation* (4) can be called[3, 9] diffusion with generator A.

When $d = 1$, $a \equiv 1$, $b(x) = -\beta x$ with $\beta > 0$, we get the Ornstein–Uhlenbeck process.

Martingale problem

An important feature of Ito integrals is Ito's formula for transformation of variables: for any $f \in C_b^2(\mathbb{R}^d)$,

$$f(Y(t)) - f(Y(0)) - \int_0^t Af(Y(s))\, ds = \int_0^t \langle \sigma(Y(s))\nabla f(Y(s)), dB(s) \rangle. \qquad (6)$$

If σ is bounded, the Ito integral on the right-hand side of eq. (6) is a martingale.

Since Y is a continuous process it induces a distribution (probability measure) on the path space $\Omega = C([0, \infty) : \mathbb{R}^d)$ = the space of $\mathbb{R}^d$-valued continuous functions on $[0, \infty)$. Denote this distribution by P_x, where x represents the starting point (that is, $Y(0) \equiv x$). Let $X(t, \omega) = \omega(t)$, $t \geq 0$, $\omega \in \Omega$. Then eq. (6) can be expressed as

$$f(X(t)) - f(x) - \int_0^t Af(X(s))\, ds = P_x - \text{martingale} \qquad (7)$$

for any $f \in C_b^2(\mathbb{R}^d)$.

The above can be used to characterize a diffusion process. The point of view taken is that the family $\{P_x : x \in \mathbb{R}^d\}$ of probability measures on Ω contains all relevant information about the diffusion process. In their fundamental work Stroock and Varadhan[11] have shown that, if a, b are bounded, continuous, then for each x there is a unique P_x such that eq. (7) holds for any $f \in C_b^2(\mathbb{R}^d)$; also under $\{P_x\}$ the coordinate projections $\{X(t) : t \geq 0\}$ form a continuous Markov process. Moreover, if the coefficients a, b are sufficiently smooth then $\{P_x\}$ agrees with the distribution of diffusion as defined earlier. Thus, the family $\{P_x : x \in \mathbb{R}^d\}$ of probability measures solving the martingale problem given by eq. (7) can be called diffusion process corresponding to A.

One may consult refs 3, 9, 11 concerning the advantages of the various approaches.

Two models

Insulated heat conduction

The problem of heat conduction in a semi-infinite bar (of uniform cross-section) with the end kept insulated is described by

$$\frac{\partial u}{\partial t}(t, z) = \frac{1}{2}\frac{\partial^2 u}{\partial z^2}(t, z), \quad t > 0, \ z > 0 \qquad (8)$$

subject to the boundary condition

$$\frac{\partial u}{\partial z}(t, 0) = 0, \quad t > 0. \qquad (9)$$

This is the one-dimensional heat equation with the Neumann condition at $z = 0$. Equations (8) and (9) describe also the concentration of a species undergoing Brownian movement (confined to $[0, \infty)$) in a dilute solution when no mass is allowed to 'escape through' 0 or to 'linger at' 0. It is well known that the fundamental solution for the above is given by

$$q(s, x; t, z) = \frac{1}{\sqrt{2\pi(t-s)}} \times \left[\exp\left\{-\frac{(z-x)^2}{2(t-s)}\right\} + \exp\left\{-\frac{(-z-x)^2}{2(t-s)}\right\}\right] \qquad (10)$$

for $0 \leq s < t$, $x \geq 0$, $z \geq 0$.

By arguments analogous to those presented earlier, it can be shown that there is a Markov process (living in $[0, \infty)$) with q as its transition probability density. This process may be called *reflected Brownian motion* (RBM). If $\{B(t)\}$ is a one-dimensional Brownian motion (in $\mathbb{R}$), then it is easily seen that $\{|B(t)| : t \geq 0\}$ is a Markov process with q as its transition density; that is, $\{|B(t)| : t \geq 0\}$ is RBM.

An inventory model

Consider the following model in queueing theory:

$$Z(t) = B(0) + I(t) - [O(t) - L(t)] = B(t) + L(t), \qquad (11)$$

$t \geq 0$, representing the *inventory process* Z in a simple two-stage flow system consisting of input (or production), output (or demand) and an intermediate buffer storage of infinite capacity. Here $I(t)$ = cumulative input up to t; $O(t)$ = cumulative potential output (or demand) up to t, $I(0) = O(0) = 0$ and $B(0) \geq 0$ is the initial inventory level. It is assumed that the demand that cannot be met from the stock on hand is lost with no adverse effect on future demand; thus, $L(t)$ can be interpreted as the demand that could not be met up to t, and $O(t)$–$L(t)$ is the actual output over $[0, t]$. Clearly, $Z(t) \geq 0$. All are assumed to be continuous stochastic processes; L is called *lost demand process* and B the *netput process*[12].

Under certain conditions of *heavy traffic*, $\{B(t)\}$ can be modelled by one-dimensional Brownian motion: viz. (a) in any short time interval $[t_1, t_2]$, the input $I(t_2)$–$I(t_1)$ and the output $O(t_2)$–$O(t_1)$ are quite large but their difference (netput) $B(t_2)$–$B(t_1)$ is not large; (b) netput increments over nonoverlapping intervals are approximately independent.

With these assumptions the set-up (11) becomes

$$Z(t) = B(t) + L(t), \quad t \geq 0, \tag{12}$$

satisfying (i) $Z(t) \geq 0$, Z is continuous in t, (ii) $Z(0) = B(0) \geq 0$, (iii) $L(0) = 0$, L is nondecreasing and continuous in t, (iv) L increases only when $Z = 0$, (v) $\{B(t)\}$ is a Brownian motion.

A look at the above indicates that a 'deterministic version' of eq. (12) with the attendant constraints is meaningful. To determine z and l such that

$$z(t) = \alpha(t) + l(t), \quad t \geq 0, \tag{13}$$

subject to (i)′–(iv)′, where (i)′–(iv)′ are the same as (i)–(iv) with l, z, α replacing, respectively, L, Z, B, and (v)′ $\alpha(\cdot)$ is a continuous function. (Here α is the known function). For a continuous function α on $[0, \infty)$ with $\alpha(0) \geq 0$ the deterministic problem is solved uniquely by taking

$$l(t) = -\inf\{\alpha(s) \wedge 0 : 0 \leq s \leq t\} \tag{14}$$

and, of course, $z(t) = \alpha(t) + l(t)$. A hard stare at Figure 1 will convince the reader!

Consequently, the stochastic problem can also be uniquely solved path by path. This problem is called *Skorohod problem* and eq. (12) is called *Skorohod equation.*

The connection and the consequences

What do the above-described models have in common? According to Levy[3], practically everything!

$\{|B(t)| : t \geq 0\}$ and $\{Z(t) : t \geq 0\}$, being continuous processes, induce corresponding distributions in the path space $C([0, \infty) : \mathbb{R})$. Levy has shown that these distributions are identical if the initial values agree. This surprising result is proved[3] by showing that Z is a Markov process with transition density q given by eq. (10). It may be noted that Levy arrived at this result purely by studying the sample path properties of Brownian motion, without any queueing theoretic considerations.

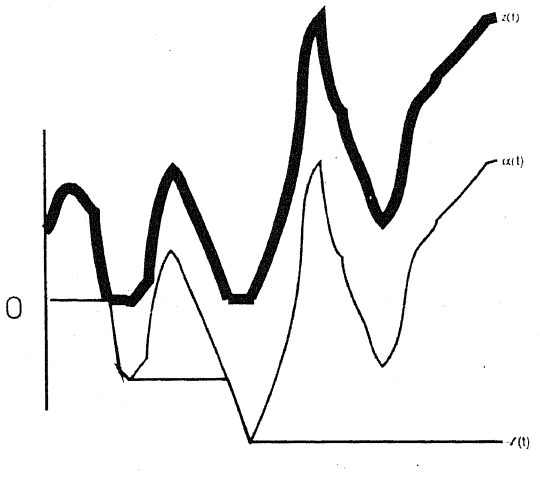

Figure 1.

Since L increases only when Z is on the boundary, L is called the *boundary local time* of Z. Local time process is one of the most esoteric objects associated with Brownian motion; in a sense high irregularity of Brownian paths makes the local time a reasonably well-behaved entity[3].

To indicate how the local time and transition density are tied up, we consider the RBM in the half-space $D = \{x \in \mathbb{R}^d : x_1 \geq 0\}$ with reflection in the inward normal direction; note that the inward normal derivative is just $\partial/\partial x_1$ at the boundary.

Let $\{(B_1(t), B_2(t), \ldots, B_d(t)) : t \geq 0\}$ be the d-dimensional Brownian motion in $\mathbb{R}^d$ (without any boundary condition). From the preceding discussion RBM in D with normal reflection at the boundary can be represented as

$$Z_1(t) = B_1(t) + L(t), \quad Z_i(t) = B_i(t), \quad i = 2, \ldots, d, \tag{15}$$

where $L(t) = -\inf\{B_1(s) \wedge 0 : 0 \leq s \leq t\}$. Also the transition probability density is given by

$$p(s, x; t, z) = q(s, x_1; t, z_1)\ r(s, \bar{x}; t, \bar{z}), \tag{16}$$

where $0 \leq s < t$, $x = (x_1, x_2, \ldots, x_d) = (x_1, \bar{x}) \in D$, $z = (z_1, z_2, \ldots, z_d) = (z_1, \bar{z}) \in D$, q is given by eq. (10) and r is the $(d-1)$-dimensional heat kernel. Using the Ito calculus and integration by parts it can be shown that

$$E_x\left[\int_0^t g(Z(r))\, dL(r)\right] = \frac{1}{2}\int_0^t \int_{\partial D} g(z) p(0, x; \alpha, z)\, d\sigma(z)\, d\alpha \tag{17}$$

for any $x \in D$ and bounded measurable function g on ∂D; here $d\sigma(\cdot)$ denotes the surface area measure on the

boundary (in this case, $(d-1)$-dimensional Lebesgue measure) and E_x denotes taking expectation under the condition $Z(0) \equiv x$.

The case of smooth domains

The importance of the Skorohod equation is that it suggests how reflecting diffusion can be represented as a solution of a stochastic differential equation. Also one may consider reflecting directions other than the normal direction, and possibly depending on $x \in \partial D$.

Let D be a domain with smooth boundary and $\gamma(\cdot)$ a smoothly varying vector field on ∂D; assume that $\langle \gamma(x), n(x) \rangle \geq \beta > 0$, $x \in \partial D$, where $n(x)$ is the inward normal. *Reflecting diffusion* in D with generator A and reflecting field γ can be defined as the process $\{Z(t)\}$ satisfying

$$Z(t) = Z(0) + \int_0^t \sigma(Z(s))\, dB(s) + \int_0^t b(Z(s))\, ds + \int_0^t \gamma(Z(s))\, d\xi(s) \qquad (18)$$

such that $\xi(0) = 0$, ξ is a continuous, nondecreasing process, ξ increases only when Z is on the boundary, and $Z(t) \in \overline{D}$ for all t. This formulation is due to Watanabe[9]. Note, however, the difference between eqs (4) and (18); in eq. (4) there is only one unknown process where (18) involves two unknown processes Z and ξ. It can be shown that eq. (18) has a unique solution which is Markov. In addition, if Z has a sufficiently regular transition probability density p then

$$\frac{\partial p}{\partial s}(s, x; t, z) + A_x p(s, x; t, z) = \delta(t-s)\delta(z-x), \quad s < t, \ x \in D \qquad (19)$$

$$\langle \gamma(x), \nabla_x p(s, x; t, z) \rangle = 0, \quad x \in \partial D \qquad (20)$$

for fixed t, z. (Observe that eq. (19) is the adjoint of the Fokker–Planck equation, known as the *backward Kolmogorov equation*.) In such a case the analogue of eq. (17) also holds. It may be noted that the notion 'reflecting direction' is justified mainly in view of eq. (20). As the sample paths of a diffusion process are nowhere differentiable, it is meaningless to say that a trajectory gets reflected in a particular direction; however, the boundary is 'reflecting' in the sense of Markov processes, viz. the sample path does not linger on the boundary and it is instantaneously returned to the interior.

Submartingale problem

As in the case of diffusion in $\mathbb{R}^d$, reflecting diffusions in smooth domains can also be characterized as solutions of 'submartingale problem', a development due to Stroock and Varadhan[10] once again. That is, for each $x \in \overline{D}$ we seek a probability measure P_x on the path space such that

(i) $P_x(X(t) \in \overline{D} \ \ \forall t \geq 0, \ X(0) = x) = 1$,

(ii) for each $f \in C_b^2(\mathbb{R}^d)$ with $\langle \gamma, \nabla f \rangle \geq 0$, on ∂D,

$$f(X(t)) - f(x) - \int_0^t Af(X(s))\, ds = P_x - \text{submartingale}, \qquad (21)$$

where X is as defined earlier. If a, b are bounded, continuous and γ bounded, Lipschitz-continuous, then the submartingale problem has a unique family $\{P_x : x \in \overline{D}\}$ of solutions; in such a case, under $\{P_x\}$ the coordinate projections $\{X(t)\}$ form a continuous Markov process and

$$E_x\left[\int_0^\infty I_{\partial D}(X(s))\, ds\right] = 0, \quad x \in \overline{D}, \qquad (22)$$

where E_x denotes the expectation with respect to P_x; eq. (22) means that the time spent on ∂D is zero. When a, b, γ are sufficiently smooth, $\{P_x\}$ agrees with the distribution of the reflecting diffusion. Thus, we have another way of looking at reflecting diffusions: the family $\{P_x : x \in \overline{D}\}$ of probability measures solving the above submartingale problem can be called[10] the reflecting diffusion process corresponding to A, γ.

Another inventory model

Consider the three-stage flow system (also called the *tandem buffer system*) outlined in Figure 2. Each buffer satisfies the earlier assumptions. Here $I_1(t)$ = cumulative input into buffer 1 up to t, $I_2(t)$ = potential transfer from buffer 1 to buffer 2 up to t = potential output from buffer 1 (potential input into buffer 2) up to t, $I_3(t)$ = potential output from buffer 2 up to t. The netput process (B_1, B_2) is defined by

$$B_1(t) = B_1(0) + I_1(t) - I_2(t),$$
$$B_2(t) = B_2(0) + I_2(t) - I_3(t). \qquad (23)$$

Let $Z_i(t)$ = content of buffer i at time t, $i = 1, 2$. We may write $Z_1(t) = B_1(t) + L_1(t)$, where $L_1(t)$ = amount of potential output lost up to t because of buffer 1 being empty. Consequently, $I_2(t) - L_1(t)$ = cumulative input into buffer 2 up to t. Therefore, applying a similar argument to buffer 2 we get $Z_2(t) = B_2(t) - L_1(t) + L_2(t)$, where $L_2(t)$ = amount of potential output lost up to t because of buffer 2 being empty. Clearly, $Z_i \geq 0$.

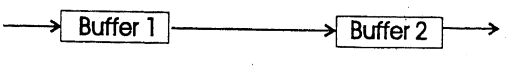

Figure 2.

In the case of heavy traffic, when the netput process can be assumed to be a two-dimensional Brownian motion $\{(B_1(t), B_2(t))\}$, the above suggests the problem: to find continuous processes $Z = (Z_1, Z_2)$, $L = (L_1, L_2)$ such that for $t \geq 0$,

$$Z_1(t) = B_1(t) + L_1(t) \geq 0,$$
$$Z_2(t) = B_2(t) - L_1(t) + L_2(t) \geq 0, \tag{24}$$

with $Z_i(0) = B_i(0) \geq 0$, L_i continuous, nondecreasing; L_i increases only when $Z_i = 0$, $i = 1, 2$. Note that Z takes values in the positive quadrant $\{(z_1, z_2): z_1 \geq 0, z_2 \geq 0\}$; the 'direction of reflection' on the boundary $\{z_2 = 0\}$ is the normal direction, whereas on $\{z_1 = 0\}$ it is the 'diagonal' direction $(-1, 1)$.

The above model is due to Harrison[12] and has given a lot of impetus to the study of reflecting diffusions in nonsmooth domains, especially to RBM in quadrant, wedge, orthant, etc. with oblique reflection at the boundary. Mathematical interest is due to the presence of corners and the reflecting direction field having 'discontinuity', and the consequent nonavailability of suitable results from the theory of partial differential equations. Here 'discontinuity' is to be understood as the difference between the reflecting direction and the normal direction being discontinuous.

Normal reflection in nonsmooth domains

What is meant by normal direction at a boundary point when the boundary is nonsmooth? Following Tanaka[13] and Lions and Sznitman[14], Saisho[15] has taken the approach given below.

For a domain D, $x \in \partial D$, $r > 0$, put $\mathcal{N}(x, r) = \{n \in \mathbb{R}^d : |n| = 1, B(x - rn, r) \cap D = \emptyset\}$, where $B(y, r)$ denotes the ball with centre y and radius r; the set $\mathcal{N}(x) = \cup_{r>0} \mathcal{N}(x, r)$. $\mathcal{N}(x)$ is defined to be the *set of all inward normal unit vectors* at x.

If ∂D is smooth at x, than $\mathcal{N}(x) = \{n(x)\}$. When D is the positive quadrant, $\mathcal{N}((0, 0)) = \{(x_1, x_2) : x_1 \geq 0, x_2 \geq 0, \quad x_1^2 + x_2^2 = 1\}$. Let $D = \{(-1, 0) \times (-1, 1)\} \cup \{(0, 1) \times (-1, 1)\}$; that is, D is a rectangle with a 'fibre' removed; note that for any x on the fibre $\mathcal{N}(x) = \emptyset$.

If D satisfies a uniform exterior sphere condition then $\mathcal{N}(x) \neq \emptyset$ for $x \in \partial D$; for such domains the deterministic Skorohod problem can be formulated as follows: Let $\alpha \in C([0, \infty) : \mathbb{R}^d)$ with $\alpha(0) \in \overline{D}$. Find a pair of continuous functions z, k such that

$$z(t) = \alpha(t) + k(t) \in \overline{D}, \quad k(t) = \int_0^t n(s)\, d|k|(s), \tag{25}$$

where $|k|(t)$ is continuous, nondecreasing, and increases only when z is on the boundary ∂D, and $n(s) \in \mathcal{N}(z(s))$ if $z(s) \in \partial D$. Note that k is $\mathbb{R}^d$-valued and is of bounded variation in every bounded interval.

Under a further technical assumption which may be called a uniform interior cone condition, it has been shown by Saisho[14], based on the work of Lions and Sznitman[16], that a unique pair of solutions exists for any α.

Moreover, if σ, b are bounded, Lipschitz-continuous, $Z(0) \in \overline{D}$, and $\{B(t)\}$ is a d-dimensional Brownian motion, then there exist unique continuous processes $\{Z(t)\}$, $\{K(t)\}$ such that Z is $\overline{D}$-valued, K is $\mathbb{R}^d$-valued with bounded variations,

$$Z(t) = Z(0) + \int_0^t \sigma(Z(s))\, dB(s) + \int_0^t b(Z(s))\, ds + K(t), \tag{26}$$

$$K(t) = \int_0^t n(s)\, d|K|(s), \tag{27}$$

where $|K|(t)$ is a continuous, nondecreasing process, and increases only when Z is on the boundary, and $n(s) \in \mathcal{N}(Z(s))$ if $Z(s) \in \partial D$. The process Z may be called reflecting diffusion in $\overline{D}$ with generator A and normal reflection at the boundary[13–15].

If Z is a quadrant/rectangle/orthant, $\sigma \equiv$ identity matrix, $b \equiv 0$, then RBM with normal reflection can be easily got from the d-dimensional Brownian motion by the method of images; in such a case Z constructed above agrees with RBM in law.

RBM with oblique reflection

Heavy-traffic approximation in queueing theory has led in recent years to an intensive study of RBM in domains like quadrant/wedge/orthant with oblique reflection. Not much is known about other diffusion processes; and even about RBM the last word is not said. We will confine ourselves to a brief discussion of RBM in a wedge; because of the 'discontinuity' at the corner, there are a few surprises around the corner!

Let D denote the wedge with angle ξ; $\partial_1 D$, $\partial_2 D$ are the two sides of the wedge. We assume that the direction of reflection is constant on each side. Let v_i denote the reflecting direction on $\partial_i D$, θ_i denote the angle v_i makes with the normal, $i = 1, 2$ (θ_i is taken to be positive if v_i points towards the corner) (Figure 3).

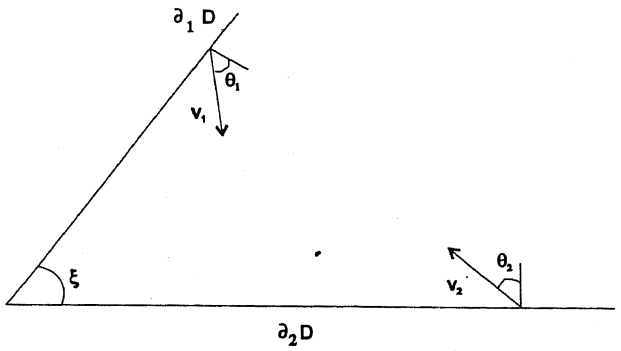

Figure 3.

In their fundamental paper Varadhan and Williams[16] defined RBM in a wedge as the solution to the following submartingale problem. Let $\mathfrak{I}$ be the collection of all smooth functions f on $\mathbb{R}^2$ such that f is constant near $(0, 0)$ and $\langle v_i, \nabla f\rangle \geq 0$ on $\partial_i D$, $i = 1, 2$. Let Ω, X be as before. A family $\{P_x : x \in \overline{D}\}$ of probability measures on Ω is a solution to the submartingale problem corresponding to $((1/2)\Delta, v_1, v_2)$ if the following hold for each $x \in \overline{D}$:

(i) $P_x(X(t) \in \overline{D} \ \ \forall t \geq 0, \ X(0) = x) = 1$;

(ii) for any $f \in \mathfrak{I}$

$$f(X(t)) - f(x) - \int_0^t \frac{1}{2}\Delta f(X(s))\, ds = P_x - \text{submartingale}; \tag{28}$$

(iii) $$E_x \int_0^\infty I_{\{0\}}(X(s))\, ds = 0, \tag{29}$$

where $\Delta = \partial^2/\partial x_1^2 + \partial^2/\partial x_2^2$. Set $(\theta_1 + \theta_2)/\xi$. The parameter α determines crucially the behaviour of the submartingale problem[16], viz.:

(a) $\alpha \leq 0$. There is a unique solution to the problem, and the corner is never visited.
(b) $0 < \alpha < 2$. There is a unique solution. The process hits the corner with probability one, instantaneously leaves the corner.
(c) $\alpha \geq 2$. There is *no* solution satisfying (i)–(iii) above. However, for each $x \in \overline{D}$ there is a unique P_x satisfying (i) and (ii); this P_x is supported on those paths which reach the corner and terminate there; that is, the process is *absorbed* at the corner.

Note that if $\theta_i = 0$, $i = 1, 2$, we have the case of normal reflection, and the solution of the submartingale problem is the distribution of the process considered in the previous section with, of course, $\sigma \equiv$ identity matrix, $b \equiv 0$.

The condition $\alpha > 0$ roughly means that there is a net push towards the corner. In such a case the corner is hit, and if the push is beyond a critical level (viz. $\alpha \geq 2$), the corner becomes an absorbing barrier! This is a surprising development as diffusions in $\mathbb{R}^d$ and in smooth domains (with $d \geq 2$) do not hit any specified point.

Proof of the result of Varadhan and Williams[16] centres around the function

$$G(r, \theta) = \begin{cases} r^\alpha \cos(\alpha\theta - \theta_2), & \alpha \neq 0, \\ \log r + \theta \tan\theta_2, & \alpha = 0. \end{cases} \tag{30}$$

which is the function (in polar coordinates) satisfying $\Delta G = 0$ in D, $\langle v_i, \nabla G\rangle = 0$ on $\partial_i D \backslash \{(0, 0)\}$, $i = 1, 2$.

Another surprising result, due to Williams[17], is that RBM in a wedge (that is, the solution of a submartingale problem) cannot be realized as a semi-martingale for $1 < \alpha < 2$; in other words, representation in terms of a stochastic differential equation (s.d.e) is not possible! This again is in contrast with diffusions in $\mathbb{R}^d$ or in smooth domains.

It may be mentioned that when D = quadrant, $\theta_i \geq 0$, $i = 1, 2$, $\theta_1\theta_2 < 1$, Harrison and Reiman[12, 17] have constructed RBM as the solution of an s.d.e by considering a modified Skorohod problem. Of late there has been considerable interest concerning the Skorohod problem with oblique reflection in nonsmooth domains.

For more information about RBM with oblique reflection the interested reader may refer to the forthcoming survey article by Williams[17].

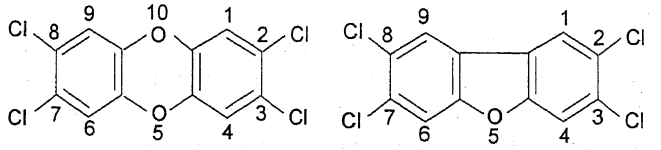
Structural, clinical and transmission aspects of dioxins – Potential environmental pollutants

C. Ganesh Kumar and K. Jayaraj Rao

Dioxins are toxic and potent carcinogenic compounds formed as contaminants in milk and foods. Their occurrence, structure, prevalence in different food products, transmission to man and detection methods are discussed briefly. The dioxins and related compounds are found as trace contaminants in the synthesis of several commercial products, importantly chlorophenols. Dioxins have also been reported to be present in cigarettes, smoke and ash. The air-borne dioxins are transmitted to man either by direct inhalation or via forage, livestock, milk and meat. Mothers who have dioxins in the body could transfer them to the infants through breast milk, which may lead to late haemorrhagic disease in the newborn infants. It is important that there should be a check on the emission of 2,3,7,8-tetrachlorodibenzo-p-dioxins by industries, and pollution laws should take cognizance of these toxic compounds. This aspect is more relevant to India in view of the rapid industrialization taking place today.

IN the recent past, the environmental issues have become a matter of increasing concern in most of the countries. With ever-increasing human activity and industrialization, the number of pollutants to be dealt with are also increasing. Of these pollutants, dioxins – a family of compounds like polychlorinated dibenzo-*p*-dioxins (PCDDs) and polychlorinated dibenzofurans (PCDFs) – are known to be potent carcinogenic compounds and pose health risk to man. Of several dioxins and their congeners, 12 are of utmost importance because of their high toxicity.



Dioxins are not synthesized commercially, but are formed as trace contaminants during the synthesis of several commercial products, mainly chlorophenols. For example, 2,3,7,8-tetrachlorodibenzo-*p*-dioxin (TCDD) is formed as a contaminant in the synthesis of 2,4,5-trichlorophenol, which is used in the manufacture of 2,4,5-trichlorophenoxy acetic acid (2,4,5-T), a broad spectrum herbicide and defoliant. Several other chlorophenols have wide usage as mold inhibitors, fungicides, insecticides and disinfectants. Of these, the most important one is pentachlorophenol, used as a fungicide for slime control during the manufacture of paper pulp, tanning of leather, etc.

Structure

The typical structure of a dioxin is shown in Figure 1. The dioxins have 75 possible chlorine-substituted bidenzo-*p*-dioxin isomers and 135 possible chlorine-substituted dibenzofuran congeners. The various isomers of dioxins formed due to the number and the position of the chlorine atoms are associated with the degree of toxicity. However, not all isomers are toxic.

Sources of dioxins

The major sources of these compounds are the impurities in chlorinated chemical wastes and the contaminants in ash and gas. Most of the sources are anthropogenic. Some PCDD and PCDF emissions arise from various combustion processes, including the incineration of municipal solid wastes (MSW) or hazardous wastes[1,2], power-producing stations using fossil fuels, and smaller systems such as private heating systems, fireplace and automobiles. Other industrial processes involved include the pulp and paper industry, steel mills, metal refining and the smelting industry. Releases are also reported to occur during hazardous waste accidents, illegal dumping, waste oil releases, and the emission of residues of treated wood, fly ash, and the production and application of pesticides[3]. There are genuine concerns that these emissions could also contaminate animal feeds and human foods such as milk, meat and vegetables[1,4]. The presence of these substances in the chlorine-bleached paper cartons used for milk packaging has also been reported[5,6]. The PCDDs and PCDFs could migrate from

2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) 2,3,7,8-tetrachloro-dibenzofuran (TCDF)

Figure 1. Structure of a dioxin and its congener.

C. Ganesh Kumar and K. Jayaraj Rao are in the Dairy Microbiology Division and Dairy Technology Division, respectively, National Dairy Research Institute, Karnal 132 001, India.

the bleached-paper cartons into the milk during storage. Among several factors which influenced the extent of this migration were the contamination level of the carton and the time of storage[7]. Reports reveal the presence of dioxins even in other food products like chicken and pork[8], fish and shell fish[9].

Permissible and prevalent levels of dioxins

In general, the dioxin content is represented by TCDD toxic equivalents used for assessing and comparing the dioxin and furan contents found in analyses. The proposed tolerable weekly intake of dioxins should not exceed 35 pg TCDD toxic equivalents per kg body weight, as recommended by Environmental Protection Agency (EPA) of the United States[10].

The dioxins have been detected frequently in milk, blood and adipose tissue and the concentrations varied in different tissues corresponding to the fat content. Cow milk is reported to contain 1.5 pg of dioxin/g fat[10]. Dioxins may find their way into the milk through cattle feed, however, some migration was also shown from milk cartons to the extent of 40 pg and 750 pg of TCCD and TCDF per kg fat, respectively. According to the estimates, the daily intake of TCDD toxic equivalents from three glasses of such contaminated milk exceeded the acceptable daily dose[11]. Comparatively, higher dioxin contents are reported in animal products. Over 60% of fat samples of chicken and pork in the study[8] contained more than 10 ng/g of pentachlorophenol (PCP). Of the poultry liver samples, 27% contained more than 50 ng of PCP per gram of liver. Moreover, PCP is known to contain a variety of chlorinated dibenzo-*p*-dioxins and chlorinated dibenzofurans[12].

There are alarming reports on the presence of chlorinated dioxins and dibenzofurans in human milk from several countries. Human milk may contain 10–50 times of these contaminants than cow milk or milk substitutes[13]. Analysis of human milk samples from South Africa, Pakistan, USA, Vietnam and England revealed dioxin toxicity levels as ranging from 8 to 23 ng/kg[14]. But, according to the analytical study conducted by the Federal Health Office (FHO), Berlin, the average daily intake of PCDD/PCDF by a baby was found to be 90 pg/kg body weight toxicity equivalents on a fat basis[15], which exceeds the permissible limits.

Transmission of dioxins to man

The potential source of human exposure to dioxins are phenoxy herbicides and airborne emissions resulting from combustion and waste disposal. The dioxins make an entry into human body through inhalation of contaminated air, but the main sources responsible for entry into human body are the milk and other food products. The dioxins are deposited on the forage/feed and soil.

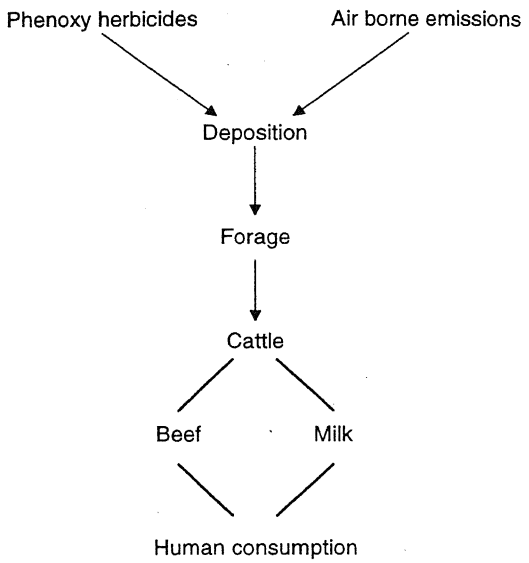


Figure 2. Flowchart for the transmission of dioxins to man.

They enter the body system of cattle when the latter ingest the contaminated feed[4, 17] or soil during grazing[16] (Figure 2). Of the total dioxins taken in by a cow, approximately 20% of the TCDD toxic equivalents are reported to be excreted in the milk[17].

Human population might be prone to dioxins where eating of smoked foods like sausages, fish and cheese is prevalent. It is important in this context to mention some of the smoked Indian dairy products like *Bandal* cheese and *Chhurpi*. *Chhurpi* is severely smoked and dried before selling in the market. This product is regularly consumed by tribal people and no studies as yet have been conducted to check possible dioxin transmission to these people. Another important source of dioxins may be the *khoa*, which is inadvertently smoked while being made over firewood in villages. This practice, however, is now discouraged and instead steam pans are used by the organized sector. Bluthgen and Heeschen[18] showed that 50% of average daily dioxin intake could be via milk products.

Studies relating to transmission of dioxins and their congeners have drawn much attention, especially with regard to transfer of these compounds from mother to child. The main factors influencing the transfer are the mother's dietary habits and personal habits such as cigarette smoking. The presence of dioxins in cigarette smoke has already been proved[19]. It could be said that in this modern society, more so in the western society, smoking even by pregnant women has become a fashion, which may lead to the passage of dioxins from the mother to child. Effects of passive smoking have also to be considered. Mothers who have dioxin content could transfer them to the infants through breast milk which may lead to late haemorrhagic disease in the newborn child[20]. In spite of these, encouragement of breast feed-

ing is recommended as its positive effects are considered more important than the risk of dioxins[21].

Clinical manifestations of dioxins

The dioxin 2,3,7,8-TCCD on long-term effect in small doses is carcinogenic, produces adverse reproductive effects and alters the body's immune response. Human beings exposed to large amounts of dioxins show many different symptoms like psychological disturbances, various sorts of physical disturbances, and neurological effects. The toxic syndromes produced by TCDD and related compounds[22] are:

1. Wasting syndrome.
2. Lymphoid ovulation – TCCD & congeners produce a loss of lymphoid tissue, especially in the thymus, but also in the spleen and lymph nodes.
3. Hepatotoxicity – TCCD and related compounds produce hepatotoxicity in all species even at low doses well below the lethal dose.
4. Gastric lesions.
5. Urinary tract hyperplasia. In the guinea pig, monkey and cow the transitional epithelial lining of the urinary tract (renal pelvis, ureter and urinary bladder) proliferates to 2–3 times its normal thickness.
6. Chloracne, a rare and potential debilitating disease, but important acneiform eruption is often associated with the ingestion of chlorinated phenolic agents such as dioxins.

Italian researchers have shown TCDD to produce chick oedema disease in fowls. Postmortem examination of the intoxicated fowls showed subcutaneous oedema, hyperpericardium, ascites, enlarged liver, oedema of myocardium, lungs and skeletal muscle, atropy of lymphoid tissue of the spleen and atropy of ovaries/testes[23,24].

Detection and quantification

Detection procedures vary from laboratory to laboratory and also with the type of sample to be analysed. The most commonly employed are chromatographic, spectrometric or immunological methods.

The dioxins and related compounds are soluble in organic solvents and hence are extracted from a product using acetone–hexane mixtures or hexane alone. These are then purified and chromatographed before determination by a combination of gas chromatography and mass spectrometry (GC–MS)[25]. Other techniques like capillary column high-resolution gas chromatography/high-resolution mass spectrometry (HRGC/HRMS), packed column gas low-resolution gas chromatography/high-resolution mass spectrometry (LRGC/HRMS) and radioimmunoassay have also been employed[26, 27]. The detection limits varied from 0.005 to 6 pg/g of the sample analysed.

Conclusions

Reports till date on dioxins and related compounds establish that these compounds could be a potential health risk in the long run if adequate precautionary measures are not taken. This is significant at a time when all the countries in the world are planning for a concerted action to check environmental pollution. Incidence of dioxins is high in industrialized countries and extensive work is being carried out in countries like USA, Germany, Sweden, Japan, etc. In the Asian context, India is the highest producer of livestock, and thus the dependence of humans on livestock and its products is high. These livestock are dependent on the soil and plant systems, which are being highly influenced by the 'modern agricultural systems'.

India is entering a fast growth phase of industrialization. The emissions from the chemical industries will result in the emission of PCBs, PCDDs and PCDFs in the surrounding environment, which will have an impact on the soil–plant systems of that area. It is desirable to assess the TCDD values in soil and crops around the sources of emission. Several studies have been attempted to determine the formation mechanism of PCDD/PCDF, but there still exist many areas where the information is incomplete.

Sufficient data are lacking in India to compare the levels of dioxin emission and consumption with the standards already established in developed countries. The standards and check levels of the industries around the farms should be introduced and implemented to the maximum level.

The birth of the semiconductor superlattice*

L. Esaki

IN 1969, research on artificially structured materials was initiated with a proposal for an engineered semiconductor superlattice with a one-dimensional periodic potential by Esaki and Tsu[1,2]. In anticipation of advancement in controlled epitaxy of ultrathin layers, two types of superlattices were envisioned: doping and compositional, as shown at the top and bottom of Figure 1, respectively.

Before arriving at the superlattice concept, we were examining the feasibility of structural formation of potential barriers and wells that were thin enough to exhibit resonant tunneling[3]. A resonant tunnel diode[4,5] appeared to have more spectacular characteristics than the Esaki tunnel diode[6], the first quantum electron device consisting of only a single tunnel barrier. It was thought that advanced technologies with semiconductors might be ready for demonstration of de Broglie electron waves. Resonant tunnelling can be compared to the transmission of an electromagnetic wave through a Fabry–Perot resonator. The equivalent of a Fabry–Perot resonant cavity is formed by the semiconductor potential well sandwiched between the two potential barriers.

The idea of the superlattice occurred to us as a natural extension of double-, triple- and multiple-barrier structures: the superlattice consists of a series of potential wells coupled by resonant tunnelling. An important parameter for the observation of quantum effects in the structure is the phase-coherent, length which approximates to the electron mean free path. This depends on bulk as well as the interface quality of crystals, and also on the temperatures and values of the effective mass. As schematically illustrated in Figure 2, if characteristic dimensions such as superlattice periods or well widths are reduced to less than the phase-coherent length, the entire electron system will enter a mesoscopic quantum regime of low dimensionality, being in a scale between the macroscopic and the microscopic. Our proposal was indeed to explore quantum effects in the mesoscopic regime.

The introduction of the one-dimensional superlattice potential perturbs the band structure of the host materials, yielding a series of narrow subbands and forbidden gaps which arise from the subdivision of the Brillouin

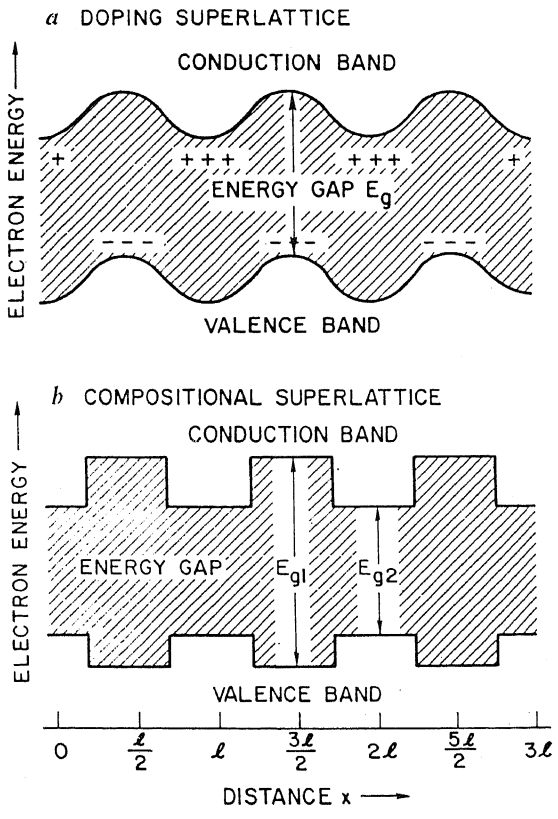

Figure 1. Spatial variation of the conduction and valence band edges in two types of superlattices: *a* doping; *b* compositional.

L. Esaki is the President of the University of Tsukuba, Ibaraki 305, Japan.

*Opening scientific address delivered at the International Conference on Physics and Industrial Development: Bridging the Gap, New Delhi, 17–19 January 1994. This article is reproduced from *Physics and Industrial Development: Bridging the Gap* (Chandrasekhar, S., ed.), Wiley Eastern, 1995. Copies can be procured from the Centre for Liquid Crystal Research, P. O. Box. 1329, Jalahalli, Bangalore 560 013, India.

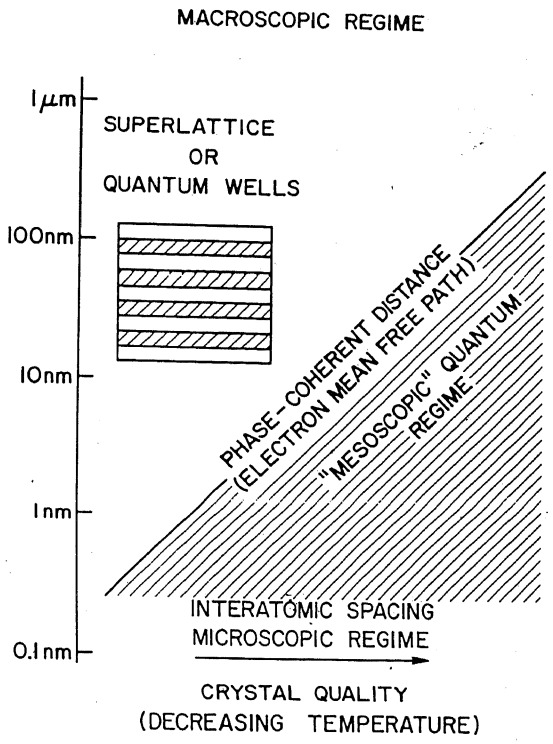

Figure 2. Schematic illustration of a 'mesoscopic' quantum regime (hatched) with a superlattice or quantum wells in the inset.

zone into a series of minizones. Thus, the superlattice was expected to exhibit unprecedented electronic properties. At the inception of the superlattice idea, it was recognized that the long, tailored lattice period provided a unique opportunity to exploit electric-field-induced effects. The electron dynamics in the superlattice direction was analysed for conduction electrons in a narrow subband of a highly perturbed energy–wave-vector relationship. The result led to the prediction of the occurrence of a negative differential resistance at a modestly high electric field, which could be a precursor of the Bloch oscillation. The superlattice, apparently, allows us to enter the regime of electric-field-induced quantization: the formation of Stark ladders,[7,8] for example, can be proved in a (one-dimensional) superlattice,[9] whereas in natural (three-dimensional) crystals the existence and real nature of these localized states in a high electric field have been controversial[10,11].

This was, perhaps, the first proposal which advocated to the engineer with advanced thin-film growth techniques a new semiconductor material designed by applying the principles of the quantum theory. The proposal was indeed made to the US Army Research Office (ARO), a funding agency, in 1969, having daringly stated, with little confidence in a successful outcome at the time, 'the study of superlattices and observations of quantum-mechanical effects on a new physical scale may provide a valuable area of investigation in the field of semiconductors'.

Although this proposal was favourably received by ARO, the original version of the paper[1] was rejected for publication by *Physical Review* on the referee's unimaginative assertion that it was *too speculative* and involved *no new physics*. The shortened version published in *IBM J. Res. Develop.*[2] was selected as a Citation Classic by the Institute for Scientific Information (ISI) in July 1987. Our 1969 proposal was cited as one of the most innovative ideas at the ARO 40th Anniversary Symposium, Durham, North Carolina, 1991.

At any rate, with the proposal, we initiated such a formidable task as to make a *gedanken* experiment a reality. In some circles, the proposal was criticized as close to impossible. One of the objections was that a manmade structure with compositional variations in the order of several nanometers could not be thermodynamically stable because of interdiffusion effects. Fortunately, however, it turned out that interdiffusion was negligible at the temperatures involved.

In 1970, Esaki *et al.*[12] studied a GaAs–$GaAs_{0.5}P_{0.5}$ superlattice with a period of 20 nm synthesized with CVD (chemical vapour deposition) by Blakeslee and Aliotta[13]. Although transport measurements failed to reveal any predicted effect, the specimen probably constituted the first strained-layer superlattice having a relatively large lattice mismatch. Early efforts in our group to obtain epitaxial growth of $Ge_{1-x}Si_x$ and $Cd_{1-x}Hg_xTe$ superlattices were soon abandoned because of the rather serious technological problems at that time. Instead, we focused our research effort on compositional GaAs–$Ga_{1-x}Al_xAs$ superlattices grown with MBE (molecular beam epitaxy). In 1972, Esaki *et al.*[14] found a negative resistance in such superlattices, which was, for the first time, interpreted in terms of the superlattice effect.

Following the derivation of the voltage dependence of resonant tunnel current[5], Chang *et al.*[15] observed the current–voltage characteristics with a negative resistance. Subsequently, Esaki and Chang[16] measured quantum transport properties in a superlattice with a narrow bandwidth, which exhibited an oscillatory behaviour. Tsu *et al.*[17] performed photocurrent measurements on superlattices subject to an electric field perpendicular to the plane layers with the use of a semitransparent Schottky contact, which revealed their miniband configurations.

Heteroepitaxy is of great interest for the growth of compositional superlattices. Innovations and improvements in epitaxial techniques such as MBE and MOCVD (metalloorganic chemical vapour deposition) have made it possible to prepare high-quality heterostructures. Such structures possess predesigned potential profiles and impurity distributions with dimensional control close to interatomic spacing. This great precision has cleared access to the mesoscopic quantum regime[18,19].

Since a one-dimensional potential can be introduced along with the growth direction, famous examples in the

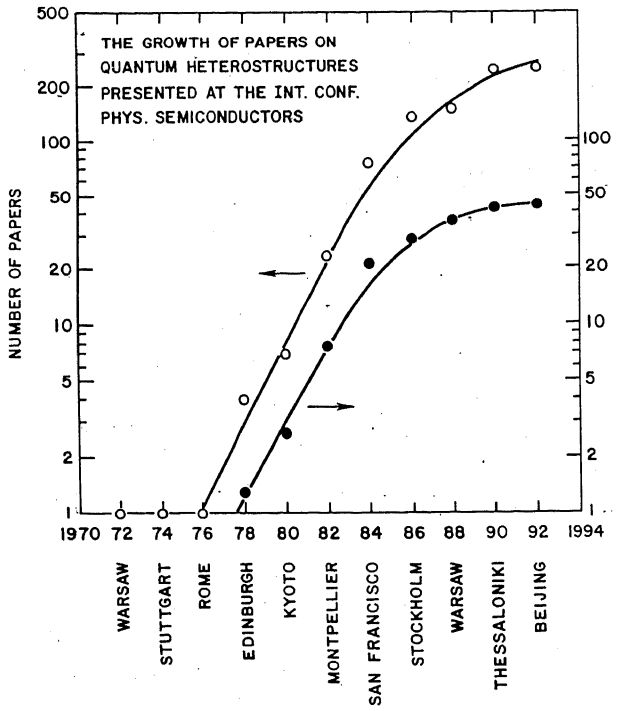

Figure 3. Growth in relevant papers at the biennial International Conference on the Physics of Semiconductors.

history of one-dimensional mathematical physics, including the above-mentioned resonant tunnelling[3], Kronig–Penney bands[20], Tamm surface states[21], Zener band-to-band tunnelling[22], and Stark ladders including Bloch oscillations[7–9], all of which had remained more or less textbook exercises, could, for the first time, be practised in a laboratory. Thus, do-it-yourself quantum mechanics is now possible, since its principles dictate the details of semiconductor structures[23].

We have witnessed remarkable progress in semiconductor research of superlattices and quantum wells over the last two decades. Our original proposal[1] and pioneering experiments apparently triggered a wide spectrum of experimental and theoretical investigations on this subject. A variety of engineered structures exhibited extraordinary transport and optical properties which may not even exist in any natural crystal. Thus, this new degree of freedom offered in semiconductor research through advanced material engineering has inspired many ingenious experiments, resulting in observations of not only predicted effects but also totally unknown phenomena. As a measure of the growth of the field, Figure 3 shows the number of papers related to the subject and the percentage of the total presented at the biennial International Conference on the Physics of Semiconductors. After 1972, when the first paper[14] came on the scene, the field went through a short period of incubation and then experienced a phenomenal expansion in the 1980s. It appears that nearly one-half of semiconductor physicists in the world are working in this area. Activity in this new frontier of semiconductor physics has in turn given immeasurable stimulus to device physics, provoking new ideas for applications. Thus, a new class of transport and optoelectronic devices has emerged. In this interdisciplinary research, there have been numerous beneficial cross-fertilizations. I hope this article provides some flavour of the excitement associated with the birth of the semiconductor superlattice.

NMR studies on the Myb-DNA system

P. K. Radha, Anup Madan, L. C. Padhy and R. V. Hosur

Tata Institute of Fundamental Research, Homi Bhabha Road, Bombay 400 005, India

NMR structural studies on a bacterially produced DNA binding domain of *Drosophila* c-Myb protein as well as its cognate DNA sequence carried out in our laboratory have been surveyed. The structure of a self-complementary dodecamer DNA containing the Myb responsive element (TAACGG) has been determined to atomic resolution by the combined use of two-dimensional NMR, spectral simulations, restrained energy minimization and distance geometry calculations. The structure is seen to possess novel features which may play important roles during its interaction with the Myb protein. The DNA binding domain of c-Myb protein was seen to have a hydrophobic core and we have identified the types of residues contributing to its formation. Residues contributing to the hydrophobic core formation are seen to be well spread out over the whole length of the 160 residues in the protein and include isoleucines, valines, leucines, alanines threonines, aromatic residues, glutamines and possibly aspartates. Our experimental data in combination with those of others indicate that some of the amino acid residues which form the helical motifs that directly interact with DNA may also be a part of the hydrophobic core.

NUCLEAR magnetic resonance (NMR) spectroscopy has grown leaps and bounds during the last decade, establishing itself as the single most reliable technique for precise determination of three-dimensional (3D) structures of biological macromolecules in solution[1]. Starting from the discovery of Fourier transform NMR[2] in the 1960s, a series of developments such as multidimensional NMR[3], rotating frame experiments[4], inverse detection techniques[5] and gradient enhancement techniques[6] have contributed to the possibility of 3D structure determination of proteins and nucleic acids having molecular weights (MWs) as large as 20 kDa. Nearly a hundred protein structures and a similar number of nucleic acid structures in the MW range of 5–15 kDa have been determined to date with the above techniques. The developments in NMR have been facilitated by parallel developments in other areas, namely computer technology and genetic engineering, the former contributing to data-handling, spectrometer control and data-processing abilities and the latter contributing to the production of desired molecules in large quantities. The developments are still occurring at a rapid pace and the objective is to push the molecular size limits to even higher ranges of 30–40 kDa. These developments will take us in the realm of biology, providing insights into structure–function relationships in biomolecules.

The c-Myb protein is a proto-oncogene product which binds to DNA in a sequence-specific manner[7,8]. The protein functions as a transcriptional regulator in vertebrates and activates a large number of genes corresponding to different proteins[9–16]. The DNA binding activity of the protein is mediated by a region close to its amino terminus[17,18]. This domain contains three imperfect, tandem repeats of 51–53 amino acid residues and is represented in general as R1–R2–R3 (or R1R2R3). Each of the repeat units contains three tryptophan residues that are evenly spaced, 18–19 amino acids apart, and are evolutionarily conserved. Besides, the sequences corresponding to the DNA binding domains of the Myb proteins are highly conserved through evolution and have been detected in as widely divergent species as yeast, *Arabidopsis*, *Zea Mays*, *Drosophila*, chicken, mouse and man[19,20]. It is, therefore, envisioned that the tryptophan residues play an important role, directly or indirectly, in sequence-specific DNA binding. This notion is further supported by site-directed mutagenesis experiments, where replacement of tryptophans at many positions was found to affect drastically the DNA binding properties of the R1R2R3 protein[21].

The three-dimensional structure of the R1R2R3 protein is not yet known. To date, there have been three reports of nuclear magnetic resonance (NMR) studies; one on the solution structure of R3 repeat[22] and two on the R2R3 repeats[23,24] from two different species, mouse and chicken. The sequence homology in these proteins is more than 70%, being much better in the R3 domain. In the mouse protein it was observed that both R2 and R3 repeats contain three helices each and the typical helix–turn–helix motif was present in both the domains. In the case of chicken it was observed that the R3 domain contained three helices with a helix–turn–helix motif, while the R2 domain contained only two helices. The R1 domain exhibited largest variations in sequence homology and its exact role in the DNA binding process is not yet fully understood. It is, however, known that the presence of the R1 domain enhances the DNA binding affinity of the protein.

The consensus nucleotide sequence of Myb recognition has been identified to be YAACKG; more recently, this has been extended to 8 bases as YAACKGHH, where Y = C/T, K = G/T and H = A/C/T[25]. However, since the extension has substantial variability, it is unlikely to be

involved in specific contacts with the protein. There are conflicting reports in the literature as to whether the conformation of the protein changes on complex formation with DNA or not. From gel electrophoresis experiments, indications have come that the interaction induces bending in DNA[26]. Recent NMR results on the R23-DNA complex[24] have shown that the core AAC sequence makes the maximum specific contacts with the protein side-chains and the phosphate interactions provide a greater stability to the complex.

In the last few years we have studied the structure and interactions of the *Drosophila melanogaster* (*Dm*) c-Myb protein with its specific cognate DNA sequences. We have bacterially overexpressed the DNA binding domain of *Dm*-Myb, a polypeptide of 160 amino acid residues, and examined its structure and interactions by various spectroscopic techniques[27–31]. This article gives a survey of the significant achievements, with emphasis on the NMR-derived results. First we describe the solution structure of the Myb responsive element (MRE) determined to atomic resolution, and then describe the structural aspects of the hydrophobic core, which probably plays an important role in spatially orienting the helical segments directly involved in protein–DNA interactions.

Solution structure of the cognate DNA sequence

The DNA sequence considered here is d-ACCGTTAACGGT, the underlined stretch being the Myb recognition sequence. The molecule is self-complementary and, hence, exists as a duplex in solution under the usual conditions of room temperature, neutral pH and low salt, 0.1 M NaCl. The structure has been determined by combined use of 2D NMR, restrained energy minimization and distance geometry calculations, whose details have appeared elsewhere[32]. Briefly, the following steps were involved. First, sequential resonance assignments were obtained by standard procedures based on 2D NMR[1]. Then 2D J-correlated spectra were quantitatively interpreted for extracting coupling constant information and NOE correlated spectra were semiquantitatively interpreted to obtain rough estimates of the interproton distances. In the next stage, quantitative interpretation of the NOESY cross-peaks intensities in terms of 3D structure was carried out by explicit relaxation matrix calculations and iterative comparisons of the calculated and the experimental intensities. This step is described in some detail in the following paragraphs.

Experimental peaks in a 300 ms NOESY spectrum were integrated above suitable thresholds by summing up all the points spanning the peak. Calculated NOE intensities for any starting structure were obtained by relaxation matrix calculation[33,34] followed by a scaling procedure inherent in the SIMNOE algorithm[35]. All the integrated intensities thus obtained were referenced to a particular peak in both experimental and calculated spectra for normalization and comparison. In the absence of a good fit, the structure was refined and the procedure repeated until a satisfactory fit resulted. The iterative structure refinement proceeded as follows. A set of distance constraints with upper and lower bounds was derived by looking at the NOE fits at any particular step. Then restrained energy minimization with the NOE potential defined in terms of distance violations was carried out using the software package X-PLOR[36], for about 20–200 cycles. NOE fits were checked and the distance constraint set redefined to drive the structure towards a better fit. The restrained energy minimization included also the 120 dihedral angle constraints to restrict the sugar geometries in both the strands to the

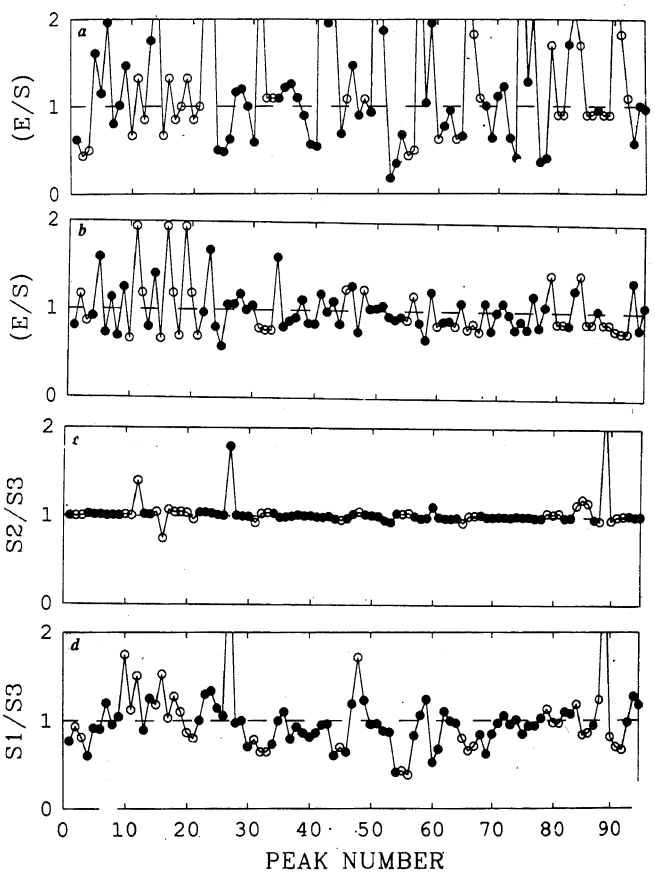

Figure 1. *a*, Comparison of experimental and calculated NOE peak intensities for the initial (B-DNA) model. Open circles represent overlapping peaks and filled circles nonoverlapping peaks. The peaks have been arranged sequencewise from left to right. *b*, Peak-to-peak fit of experimental and calculated NOE peak intensities for the final structure. *c*, Peak-to-peak fit for the two structures S2 and S3 differing by only 0.05 Å on the all-atom r.m.s.d. scale. *d*, Comparison of simulated NOE intensities for the final structure S1 and another distance geometry generated structure S2, which differs from S1 to an extent of 0.68 Å on the all-atom r.m.s.d. scale.

ranges derived from the coupling-constant information. The whole procedure was repeated with different starting models, and we noted that an energy-minimized B-DNA as the starting structure provided the best NOE fits at the end.

Figures 1 *a* and *b* show the initial and final fits for 95 NOE peaks for each strand of the 12-mer duplex. The NOE set consisted of 61 intranucleotide and 34 internucleotide peaks. To appreciate the adequacy of the NOE set and the quality of the fit in terms of closeness of the structure to the correct structure, we have carried out the following exercise. We selected two intermediate structures labelled S2 and S3, which had an all-atom r.m.s.d. (root mean square deviation) of 0.69 and 0.68 Å, respectively, from the final structure (labelled S1). We then compared the calculated NOEs of all the three structures and these are depicted in Figures 1 *c*, *d* in the same manner as the fits in Figure 1 *b*. These results provide a correlation between the similarity of structures and the similarity of NOE fits for the 95 peaks used. The two structures S2 and S3 which have an r.m.s.d. of 0.05 Å and thus are clearly identical have almost identical NOEs (Figure 1 *c*); the differences seen reflect the small differences in structures. Further, the structures S1 and S2, which are also close to the extent of 0.69 Å on the r.m.s.d. scale, have NOEs differing by 25–50% for a large number of peaks; a few peaks differ to a wider extent. This indicates that even as small a structural difference as 0.69 Å on the r.m.s.d. scale results in

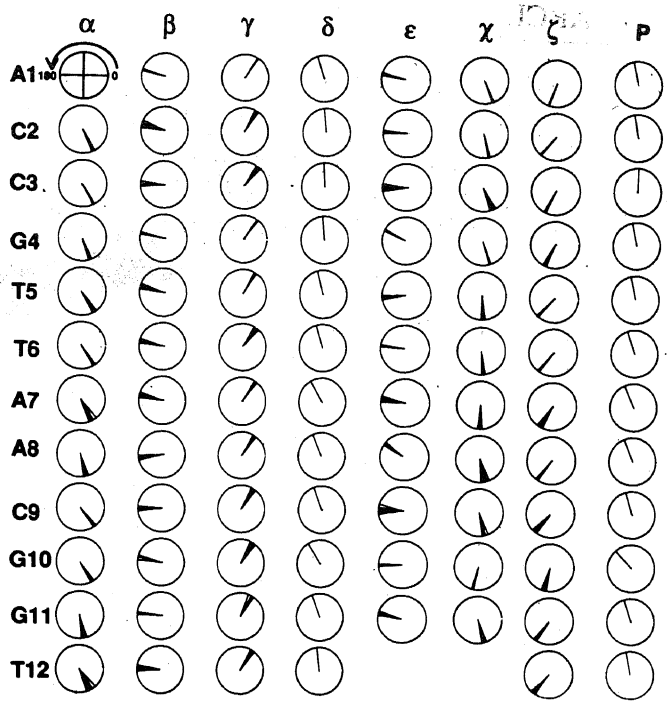

Figure 2. Analysis of the backbone torsion angles of 25 DG-generated structures. The individual torsion angles for all the nucleotides belonging to different structures are indicated by the value in degree in the corresponding dial. The direction of rotation is indicated in the first dial. The torsion angle is indicated in the top row and the nucleotide number in the leftmost column. As can be noted from the analysis, the torsion angles for all the residues are similar within ~ 5–10° for all the structures, indicating a single dominant structure for the DNA segment.

The standard values for A-DNA (– . .) and B-DNA (. . . .) models have also been indicated. *c*, Comparison of the orthogonal views of the final structure and the B-DNA structure.

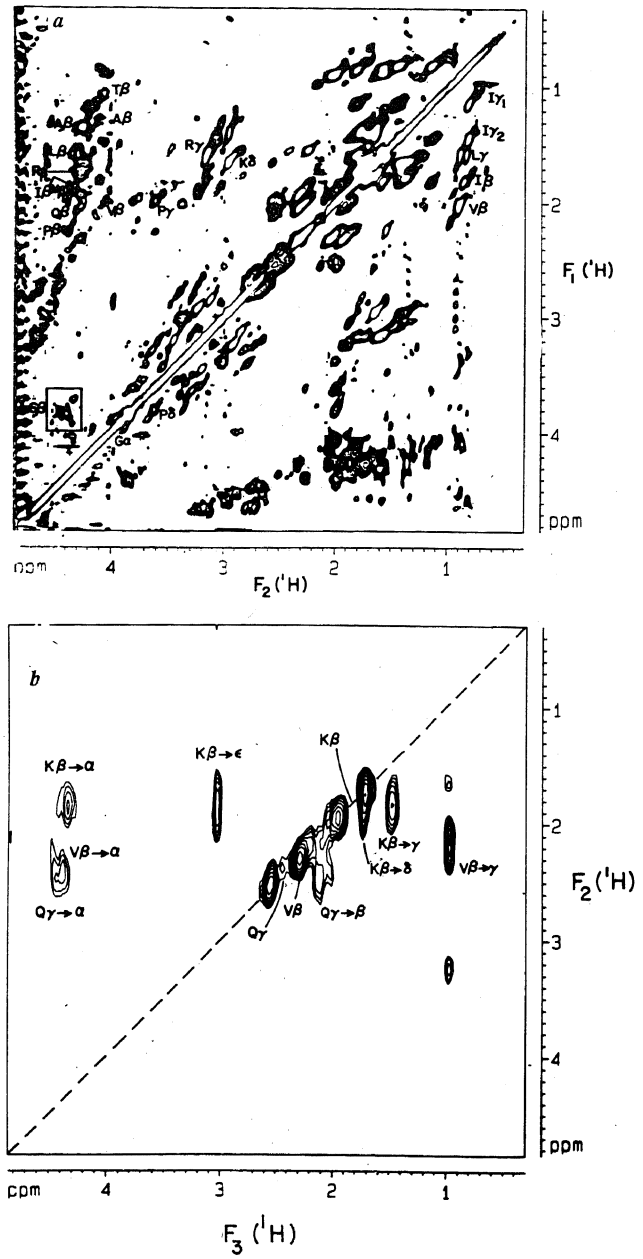

Figure 6. Experimental illustration of the spectral simplifications achieved in the 3D spectrum as compared to the 2D spectrum. *a*. Portion of 2D ^{1}H–^{1}H clean TOCSY spectrum. *b*, A ^{13}C plane through the full 3D spectrum, at a ^{13}C shift of 33.4 ppm. A number of correlations which are hard to find out clearly in the top spectrum are readily identified in the lower spectrum and these have been indicated. The spin systems of K, V and Q residues can be clearly seen.

solvent, and loss of secondary structure elements indicated that the hydrophobic core may be the most stable element since it is the last one to get disrupted by urea. The fluorescence results also indicated that all the three repeats, R1, R2 and R3, in the protein contribute to the formation of the hydrophobic core. Because of these significant observations, we have tried to characterize the nature of the hydrophobic core in terms of identifying the participating amino acids by NMR spectroscopy.

Specific monitoring and distinction of the interior residues from the exterior ones can be made in NMR by making use of the fact that the amide and other side-chain NH_2 groups lying on the surface of the protein exchange protons more rapidly with solvent compared to those in the interior of the protein. Deuterium exchange studies provide the most direct method to identify the slowly exchanging amides (exchange rates $< 10^3\ s^{-1}$) in the protein. Amides exchanging faster than this rate will not be visible in the spectra in ^2H_2O solutions. In the case of R1R2R3 protein, we observed that only four or five out of the 162 NH–C$^\alpha$H cross-peaks could be counted in the clean TOCSY spectrum in ^2H_2O solution at 16°C and these were present even after two months of keeping the protein in ^2H_2O. This implied that a small fraction of the protein is deeply buried in the hydrophobic environment and the rest of the protein is easily accessible to the solvent. We resolved to attempt a finer gradation of the exchange rates of amides by performing temperature variation experiments in H_2O solutions, that is, if the amide proton resonances are monitored as a function of temperature, the fast exchanging amides disappear from the spectra faster and this provides a useful filter to study the slowly exchanging amide protons. We may mention here that the ^{1}H spectra in ^2H_2O solutions did not show perceptible major changes as the temperature was raised slowly from 16 to 80°C. This indicated rather qualitatively that the structural core of the protein did not undergo major changes, and also, more relevantly in the present context, that the chemical shift assignments we would obtain at a higher temperature can be extrapolated to lower temperatures.

Figure 5 shows the same regions of clean TOCSY spectra of R1R2R3 protein at 16 and 80°C recorded with the same mixing time of 80 ms. Several points are noteworthy from these two spectra: (i) All the side-chain NH_2's of lysines and arginines, which can be easily identified from their characteristic relay peaks to other nonexchangeable protons along their chains, have exchanged out with water at 80°C. This implies that these two residue types lie entirely on the surface of the protein. (ii) Quite substantial simplification of the spectrum has occurred at 80°C and it is possible to count peaks in different regions; nearly 75 NH–C$^\alpha$H peaks could be counted in the fingerprint region of the spectrum at 80°C. Here it may be noted that several C$^\alpha$H protons occurring at 4.20–4.25 ppm are killed by water presaturation at 80°C. (iii) Several NH–C$^\alpha$H–C$^\beta$H relay peaks arising from aromatic residues and possibly aspartates were detectable. This identification is provisional and is based on the typical chemical shifts of C$^\beta$H protons. Actually, C$^\beta$H protons of aspargines,

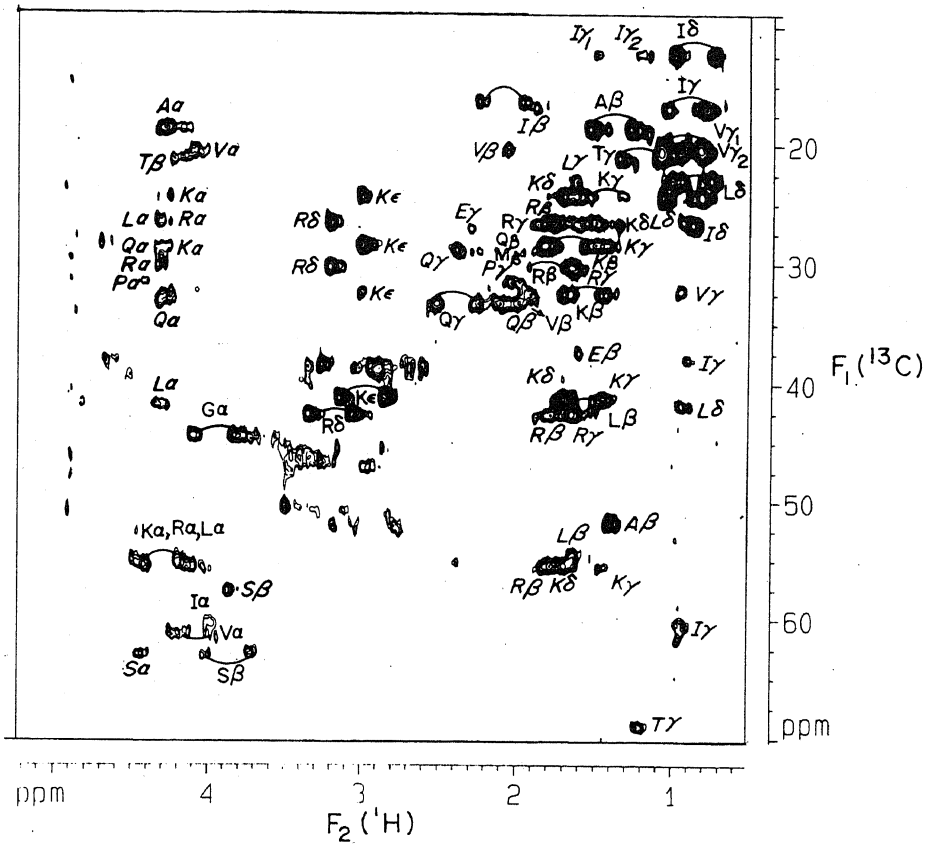

Figure 7. ^{1}H–^{13}C HMQC-TOCSY spectrum at natural abundance of the R1R2R3 protein recorded on BRUKER AMX 500 NMR spectrometer. Sample conditions: 5 mM protein, pH 5.6, temperature 16°C. 2048 t_2 and 512 t_1 points were used with carbon offset placed in the middle of the C^{β} region. The carbon spectral width was 90 ppm. Quadrature direction along F_1 was achieved by the standard TPPI procedure. The MLEV mixing time was 51 ms. No ^{13}C decoupling was employed during detection and thus the direct peaks in the spectrum retain the one-bond $^{1}J_{CH}$ coupling (they have been joined). The relay peaks are, however, single peaks. The various peak assignments indicated have been obtained by analysis of different 2D spectra and the 3D spectrum.

glutamines and cysteines are also expected in this region, but the presence of aspargines and glutamines can be easily checked from the double quantum (DQ) spectra. Indeed, the DQ spectra in H_2O showed that aspargines were absent but some glutamines were present whose $C^{\beta}H$ positions have consequently been identified. The presence or absence of cysteine was not possible to ascertain from these experiments. The number of remaining peaks suggested that both aromatic and aspartate residues were retained. (iv) There are clearly several methyl-bearing residues such as isoleucines, leucines, alanines, threonines and valines, and the NH protons of these show a reasonable spread.

Additional residue type identification of peaks at 80°C was obtained from the heteronuclear ^{1}H-^{13}C correlated 2D and 3D spectra. The spectra shown in Figure 6 illustrate how 3D spectra can be used for spin system identifications. The spectrum in (*a*) is the usual clean TOCSY spectrum in $^{2}H_2O$, which contains all the observable ^{1}H-^{1}H correlations and relay peaks for the protein. Clearly, the spectrum is highly crowded and difficult to analyse for unambiguous connectivities. The spectrum in (*b*) is a slice through the three-dimensional ^{13}C separated ^{1}H–^{1}H clean TOCSY spectrum taken at a particular carbon chemical shift. The spectrum is now simpler and the peaks can be readily identified as originating from particular spin systems. Such an analysis of all possible ^{13}C planes allows the identification of all the amino acid residues in the protein. Figure 7 summarizes all the identified spin systems in a 2D HMQC-TOCSY spectrum, which is basically a ^{1}H–^{13}C correlation spectrum including the ^{1}H–^{1}H relays at specific ^{13}C chemical shifts. The peaks in this spectrum provide a cross-check for the validity of the assignments made from 3D spectral analysis. An important observation made from this spectrum is that the methyl-bearing residues which are difficult to distinguish in ^{1}H–^{1}H correlated spectra are easily distinguished on the basis of the ^{13}C chemical shifts.

The above assignments provide a basis for the identification of the peaks in Figure 5. Figure 8 shows the specific side-chain assignments to residue types obser-

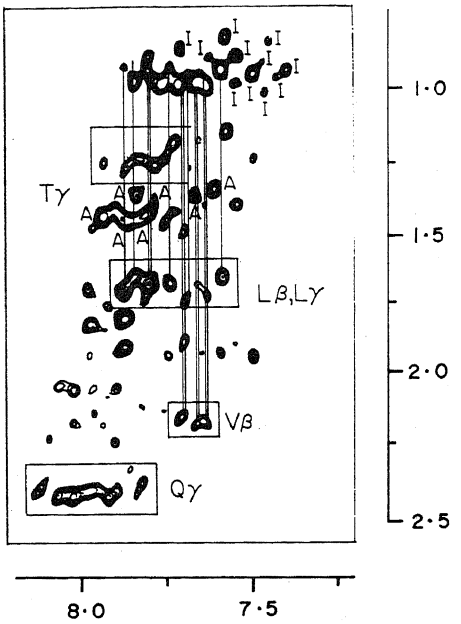

Figure 8 Specific side-chain assignments to residue types observed in the clean TOCSY spectrum (80 ms spin lock time) of R1R2R3 protein in H_2O recorded at 80°C. Cross-peaks belonging to valines and leucines are indicated by vertical lines. Peaks belonging to glutamine and threonine γ have been boxed, and those belonging to alanines have been labelled A. The 11 isoleucine γ's have been labelled as I.

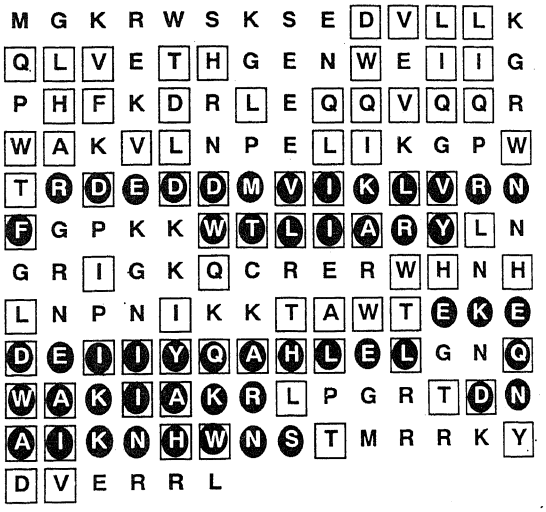

Figure 9. Amino acid sequence of R1R2R3 protein indicating the residues (boxed) for which the amides are observed at 80°C. All the residues (excepting the terminal ones) of any particular type that has been seen in the high-temperature spectrum have been marked, although we were able to count the numbers only in few cases. For example, separate identification of all peaks belonging to individual aromatic residues was not done. But the total count in the figure tallies closely with the total number of residues seen in the spectrum. We notice that the slowly exchanging amides are spread out all along the sequence, implying participation of all the portions of the protein in the formation of the hydrophobic domain. The circled residues are expected to be forming helices, from sequence comparison with R2–R3 domains of mouse and chicken c-Myb, whose NMR secondary structures have been reported recently[23, 24].

vable at 80°C that probably constitute the hydrophobic core in the R1R2R3 protein. We noticed here that backbone amide protons had reasonable spread and we could count 5–6 valines, 7 alanines, 6 threonines, 5–6 leucines, 11 isoleucines and 7–8 glutamines. There were several other peaks which originated, very likely, from aspartates and aromatic residues; the latter have hydrophobic character and hence are expected to remain shielded from the water.

Figure 9 shows the sequence-wise location of the various residues identified in Figure 8. We notice that the residues are distributed along the whole length of the protein. This indicates that all the three repeats contribute to the formation of the hydrophobic core in the protein and about 70–80 residues contribute to its formation. It is also worthwhile noting that glutamines and aspartates, which are hydrophilic residues, are also included in the above list. A possible explanation could be that they are involved in the formation of hydrogen bonds through their polar side-chains with other residues in the protein. Examination of the relative positions of the hydrophobic residues in the sequence, *vis-à-vis* the known secondary structure elements of vertebrate R1R2R3 from NMR studies in the conserved R3 and R2–R3 domains and their DNA complexes[22–24], reveals that some of the hydrophobic core residues may form parts of helices involved in specific interactions with the DNA. The helices may be lost at elevated temperatures but the hydrophobic core appears to be the last one to get disrupted[31].

Conclusions and future directions

We have described in this article structural information derived from NMR studies in our laboratory, on a specific target DNA sequence of the DNA binding domain of *Drosophila melanogaster* c-Myb protein and also on the hydrophobic core present in the protein where the DNA binds. The structure determination has unravelled important features which could constitute hot points of recognition. Extensive use of homonuclear and heteronuclear two- and three-dimensional NMR experiments has enabled gross identification of residue types involved in the formation of the hydrophobic core in the protein, which has an important role to play in DNA recognition. The hydrophobic core seems to be constituted by all the three repeats in the protein. Sequence comparison with R2–R3 domain of mouse and chicken c-Myb, for which NMR structures were reported recently, provided clues to identification of the secondary structure and of the so-called helix–turn–helix motif of DNA recognition. This provides a supplementary character to our previous work on R1R2R3–DNA interaction by fluorescence quenching studies, in that the cognate

DNA binding site of this protein is associated with a hydrophobic core element being surrounded by 4–5 tryptophans, at least one tyrosine and a cysteine[27–29].

The work reported in this paper represents an important step forward in our efforts to understand DNA–Myb interaction and recognition at the atomic level. A lot more remains to be done from the viewpoint of 3D structure determination of the protein and of the complex. Sequence-specific assignment of resonances is the most crucial step requiring the employment of a battery of multidimensional NMR experiments on isotopically (^{15}N and ^{13}C) labelled protein. Indeed, we have just successfully achieved the production of large amounts of labelled R1R2R3 protein.

Atomic-level structure determinations of the R1R2R3 and also of their segments R1R2, R2R3 and R3, which are also in the offing in our laboratory are expected to throw light on several important questions. For example: (1) What is the role of R1 repeat in specific recognition? (2) Do the individual repeats retain their structural motifs when any of the other repeats is knocked off from the protein? (3) Which are the residues making contact with the DNA and how is the specificity of interaction brought about? (4) Is it possible to alter the DNA binding specificity by structural-knowledge-based mutations in the protein?

Lithium and tungsten mineralization in Sewariya pluton, South Delhi Fold Belt, Rajasthan: Evidences for preferential host rock affinity

Subrata Banerji and M. K. Pandit*

B-130, Malviya Nagar, Jaipur 302 017, India
*Department of Geology, University of Rajasthan, Jaipur 302 004, India

'Sewariya batholith', the largest of Erinpura granite intrusions in the South Delhi Fold Belt is evolved from a two-stage subduction process. The Sewariya granitoids comprise three major mineralogical varieties, viz. hornblende–biotite granite, biotite granite and leucogranite. The hornblende–biotite granite is a deep-level I-type granite, whereas the other two are orogenic, S-type anatectic granites formed by partial melting of the same source material under varying physicochemical conditions. These two granite types also host the tungsten and lithium mineralization. The W and Li minerals show perfect separation and host rock discrimination. The W minerals are associated with biotite granite, whereas the leucogranite hosts the Li mineralization.

THE folded rock sequences of northwestern part of the Indian shield in the state of Rajasthan contain two principal well-defined Proterozoic fold belts, the early Proterozoic Aravalli and the Middle to Late Proterozoic Delhi Fold Belt. The Delhi Belt extending from Delhi in the northeast to northern Gujarat in the southwest is exposed in two discrete sectors[1], viz. North Delhi Fold Belt (NDFB) in northeastern Rajasthan and South Delhi Fold Belt (SDFB) towards southwest, with its best development in the main Aravalli hill range near Ajmer and in western Mewar. The Delhi sequence has been traced into southwestern Rajasthan but its physical continuity is interrupted by a vast expanse of alluvium, resulting in tremendous correlation uncertainties. Orogenic activities manifested by continuous polyphase acid magmatism have been documented in NDFB by 1600–1500 Ma granites and by 850–700 Ma plutonic belt in SDFB, overlapped and followed by the Malani igneous activity (740–430 Ma). The SDFB is intruded by a number of granitoid bodies ranging from minor intrusions to composite batholiths. The 22 mile long and 4 mile wide Sewariya batholith is the largest of the Erinpura granite intrusions in the northern half of the Delhi synclinorium[1].

Location and geological setting

The present work deals with the evidences of typical mutual association of specific granitoid host *vis-à-vis* tungsten and lithium mineralization in the area south of Luni river in northwestern flank of SDFB (26°30″ to 26°32′N and 74°05′ to 74°22′E) around village Sewariya in district Pali, Rajasthan (Figure 1). The geological setting of the area is shown in the detailed lithologic map (Figure 1) and the stratigraphic sequence is summarized in Table 1.

The oldest rocks encountered in the area are the Pre-Delhi metamorphites comprising mica schist, gneisses and amphibolites. These are overlain by two thick bands of marble, commonly known as 'Ras Marble'. The contact between Ras Marble and Pre-Delhi rocks is either concealed by alluvium or infested by pegmatites. The Ras Marble is coarse-grained, light grey and thickly bedded massive carbonate rock containing minor quantities of quartz, felspar along with epidote, zoisite, diopside and tremolite as accessories. A volcano-sedimentary assemblage constituting the Barotiya Group containing meta-argillite (+/– autoclastic conglomerate), tourmalinite, meta-basic volcanics, meta-gabbro, meta-arkose, marble and chert overlies the Ras sequence. The contact between Barotiya group of rocks and the Pre-Delhi metamorphites/Ras Marble is obliterated and occupied by Sewariya granitoids (SG). The meta-argillite contains quartz, biotite, plagioclase, garnet, tourmaline, staurolite, andalusite, sillimanite (fibrolite), apatite and magnetite. Tourmalinite contains mainly tourmaline and quartz besides minor opaques and biotite as accessories. The meta-volcanics of the Barotiya group exhibit bimodal composition[2]. In the present area only the mafic component having actinolite, plagioclase (andesine), quartz, sodic hornblende, epidote, apatite, leucoxene and opaques is exposed. Relict pyroxene cleavage is observed in the amphiboles. Alteration of hornblende into chlorite and plagioclase into saussurite is also seen. Three petrographic variants of meta-gabbroid bodies have been identified in the field. Marble contains discrete clasts of anhedral quartz in fine micritic mass along with zoisite, clinozoisite and apatite as common accessory minerals. Meta-arkose is dirty-white-coloured, medium-grained rock containing mainly quartz and felspars besides muscovite and apatite along with minor opaques. Meta-chert occurs as thin linear bands within meta-arkose unit in the area.

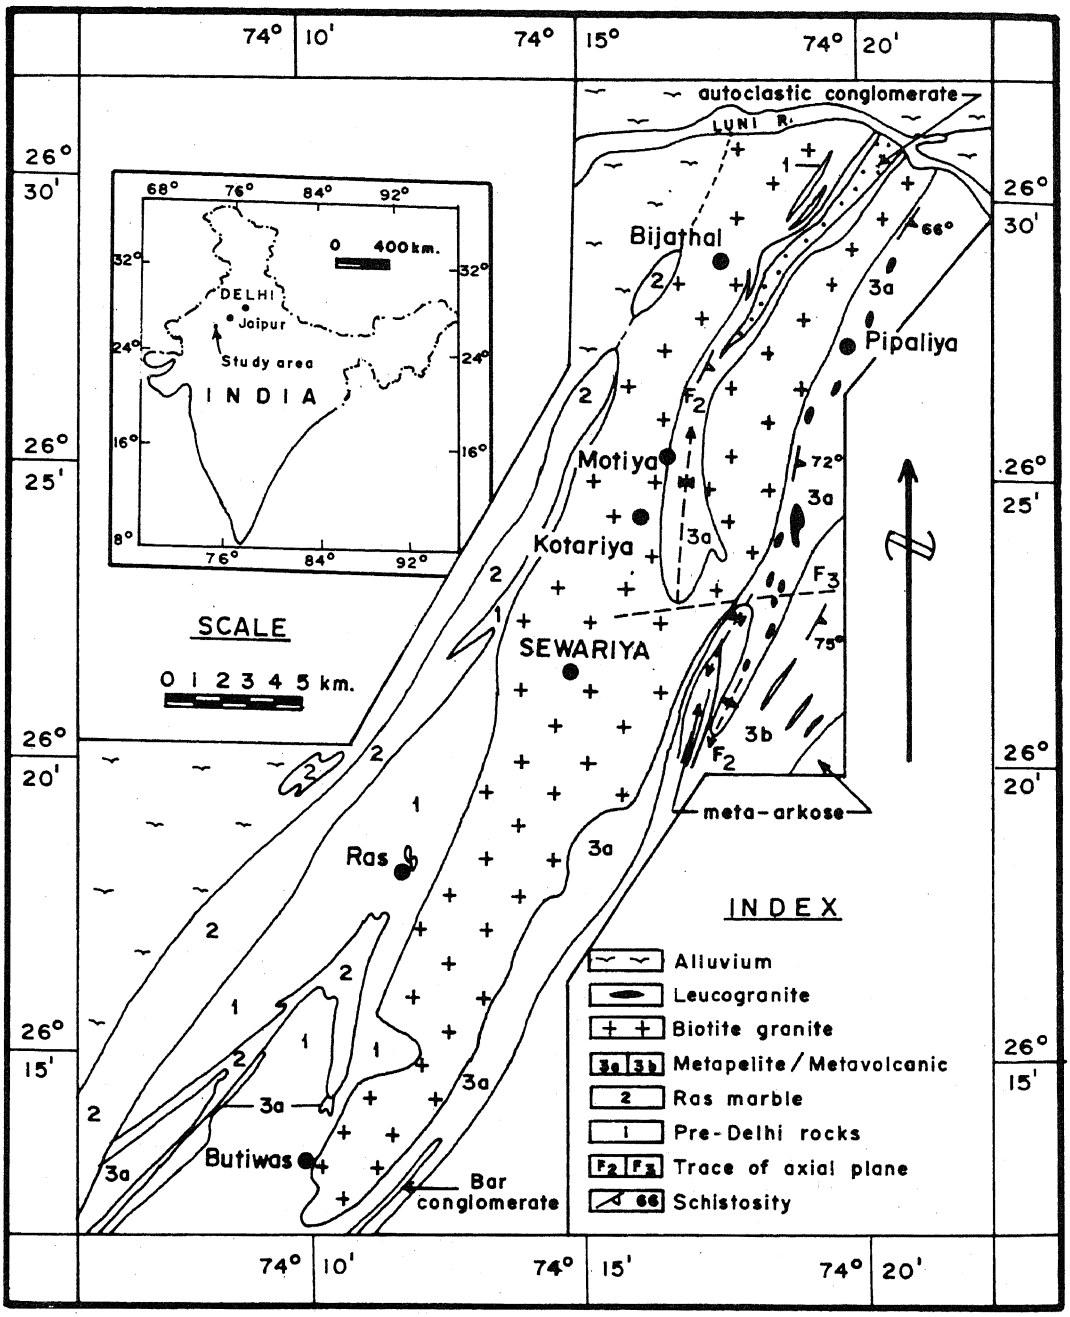

Figure 1. Lithostratigraphic map of the Sewariya region. Map of India showing the location of the study area is also given in the inset.

Various structural elements recorded in the area are in harmony with the deformations related to SDFB. The overall strike pattern, litho-contacts and linear shears of the area are in conformity with NNE–SSW-trending Aravalli orographic axis. Three generations of conformable deformational structures have been recognized in both Ras and Barotiya group of rocks, while one more phase of earlier folding is also recorded in the Pre-Delhi rocks. Shears usually follow the zones of weakness and contribute prominent linearity to the overall outcrop pattern.

The area of the present study has undergone two progressive metamorphic phases involving lower greenschist to sillimanite–almandine subfacies of amphibolite facies and subsequent anatexis, followed by a retrogressive phase of metamorphism under lower greenschist facies. The grade of metamorphism in this sector increases westwards and the isograds are parallel to the regional planar fabric.

	Ras sequence	Marble
Structural hiatus		
Pre-Delhi		Metamorphites

Granitoids and metallogeny

Three types of granitoids, viz. leucogranite, biotite granite and hornblende–biotite granite, are exposed in the present area. The latter two granite types and their associated W +/– Li +/– Sn mineralization have already been studied in detail[3]. During the present study the authors have identified the leucogranite variety and have also successfully discriminated exclusive association of tungsten mineralization with biotite granite and lithium with leucogranite–pegmatoid phase. The hornblende–biotite granite seems to be absolutely devoid of any mineralization.

Leucogranite is a fine- to medium-grained, white- to dirty-white-coloured rock occurring as small pods and irregular bodies of extremely variable size, in the eastern part of the area within meta- argillites. The smaller bodies and pegmatite veins lie concordant to the planar fabric and are often boudinaged. The typical mineral assemblage of this rock is quartz, plagioclase (mainly albite), K-felspar, muscovite, tourmaline and garnet with small amounts of apatite. Tourmaline occurs either as irregular masses or as euhedral prisms with 10–15% modal abundance. The leucogranite does not contain a single flake of biotite.

The biotite granite and the leucogranite are meta- to per-aluminous, highly fractionated in character, showing depletion of compatible elements like Fe, Mg, Ti, Ca, Ni, etc. (Table 2). The relatively more fractionated (high SiO_2, very low MgO and CaO and higher alkalies), homogeneous leucogranite has characteristic absence of biotite and zircon, implying efficient separation of melt from solid residual phases[4]. The low Li content of leucogranite (65 ppm) can be attributed to the partitioning of Li into the residual melt phase during fractionation and its ultimate segregation as Li phosphate minerals in the late-stage pegmatoid phase associated with leucogranite. The low W content of leucogranite is due to the absence of biotite phase, which is the carrier and the most suitable locale for W concentration.

Table 2. Major and trace element analysis of Sewariya granitoids. The major oxides are represented as wt% and the trace elements in ppm

	Range	Average[1]	Average[2]
SiO_2	67.71–80.18	71.83	73.62
TiO_2	0.07–0.50	0.22	< 0.05
Al_2O_3	9.67–15.60	13.13	14.88
Fe_2O_3	0.40–4.70	1.93	0.76
FeO	1.08–3.17	1.80	0.90
MnO	0.01–0.10	0.04	0.04
MgO	0.05–1.3	0.64	0.04
CaO	0.56–2.48	1.36	0.41
Na_2O	0.14–4.64	2.57	4.86

Ni	10–20	13	< 10
Zr	20–50	28	< 20
Li	20–900	135	65
W	20–100	50	< 50

[1]Average of 15 biotite granites.
[2]Average of 2 leucogranites.
< ≡ Below detection limit.

The biotite granite is heterogeneous in nature, with composition comparable to the metasediments of the area[4]. It is well differentiated, per-aluminous, orogenic, S-type granite with calc-alkaline affinities[3]. The initial I_{Sr} of 0.74552 indicates its crustal derivation from metasedimentary source rock[5]. The higher concentration of W is due to the presence of biotite as an important constituent. Higher values of Li as compared to the leucogranite (host for Li mineralization) is a result of regular partitioning of Li in the crystal phases during fractionation, resulting in its depletion in the residual melt. As such, the quartz and pegmatite veins associated with the biotite granite are devoid of any Li mineralization.

The crustal anatexis and recycling of pre-existent crustal material plays a dominant role in granitoid petrogenesis. Consequent to progressive regional metamorphism under sillimanite–almandine subfacies of amphibolite facies, anatexis takes place, giving rise to different types of granitic magmas depending mainly upon the composition of the source material, its formation level difference and the percentage of partial melting. In this context the leucogranite appears to have been formed at higher crustal levels, generated by comparatively lower percentage of partial fusion of supracrustals[6] with simultaneous removal of melt from the melting zone under water-rich conditions as evident by the presence of extensive pegmatite veins. The melt initially segregated into small bodies, which subsequently united together to form larger bodies and intruded the overlying rocks in the eastern part of the study area.

The SDFB with an ensialic rifting history contains profuse Post-Delhi granites, the older Sendra granite

and the younger Sewariya granite developed in response to the subduction process[7]. A perfect matching of the geological setting and lithological characters of the present area with pyrenes[8,9] indicates that localized rifting events associated with strike–slip motion in SDFB have affected the basin[10]. Deep circulation of ground waters also influenced the anatectic process by controlling the solidus–liquidus temperature and promoted higher percentage of partial melting to produce such a huge biotite granite pluton (Sewariya batholith), the 'largest of Erinpura granite intrusions'. The biotite granite of the area appears to have been derived from the same source material at relatively deeper levels compared to the leucogranite, involving higher percentage of partial melting under essentially 'wet' melting conditions[6].

Both leucogranite and biotite granite are high-level, syn-metamorphic and syn- to post-kinematic, anatectic granites, but the third variety, i.e. the nonfoliated hornblende–biotite granite is post-metamorphic 'deep-level' granite possibly formed either exclusively from deeper crustal material or by mixing of mantle-derived mafic magma and assimilated crustal lithologies.

The western Indian craton and its fold belts have provided important clues to the understanding of different metallotects for various mineral commodities. Incidence of wolframite was first recorded within Sewariya pluton by Rajasthan State Tungsten Development Corporation in 1987 and later a 14 km long tungsten mineralization belt was identified between Kalni in the north and Kotariya in the south[11]. The W +/– Sn +/– Li metallogeny associated with metallogenetically specialized biotite granite has been compared with similar metallogenesis of the Cordilleran arc system[3]. However, the present study reveals that the tungsten metallogeny in the eastern part of the area associated with meta-argillites (viz. Pipaliya and Pipaliya village prospects) seems to be exhalative strata-bound type. Subsequent enrichment in W content during progressive metamorphism is evidenced by enhanced W values in NNE–SSW- trending dewatering quartz veins emplaced along axial plane schistosity (S2). Evidences of later remobilization and enrichment in quartz veins associated with NNE–SSW-trending shear zones near and along the contact between Barotiya group of rocks and anatectic biotite granite have also been observed. In contrast, at Motiya, Kotariya, Bijathal, etc., the host quartz and pegmatite veins are associated with granitization process emplaced in and through channelways in the shear zones. Tungsten mineralization accompanied by greissenization and as placer deposits in Motiya block, has also been identified. The lithium phosphate minerals (sicklerite, ferrisicklerite and triphylite) bearing zoned pegmatoid and quartz veins associated with leucogranite phase occur concordantly within meta-argillites in the eastern part of the present area as an 18 km long belt. The younger discordant veins show remobilization and enrichment. Similar phosphate species of sicklerite–triphylite also occur as important accessory minerals in numerous granitic pegmatites in the Pala area[12]. The phosphate mineralogy and alteration history of these minerals indicate their crystallization at a relatively shallow depth[13]. The crystallization was facilitated by the presence of a coexisting, exsolved, volatile-rich fluid within the pegmatite magma in the upper intermediate zone only[14]. The phosphate–silicate liquid immiscibility is not essential for lithium phosphate formation under water-saturated conditions[15].

Discussion and conclusion

The relationship between leucogranite and the biotite granite in the present area is not clear as the former is occupying the synformal cores and the latter is emplaced in antiformal cores of the same deformation (DF2). Leucogranite does not contain biotite as well as tungsten, whereas biotite is the main mafic mineral in tungsten-bearing biotite granite. Pegmatitic phase is ubiquitous in leucogranite and contains lithium phosphate minerals. Though a few pegmatite veins are associated with biotite granite, they are devoid of any lithium phosphate mineralization. Pneumatolytic quartz veins are a very common feature of biotite granite, which hosts the bulk of the tungsten mineralization.

The absence of biotite and certain elements in well-differentiated leucogranite implies efficient selective separation of melt from solid residual phases during anatexis. The tungsten normally partitions along with biotite and hornblende in a granitic melt[16], consequently, the biotite-free leucogranite of the present area is devoid of any associated tungsten. The absence of absolute pegmatitic conditions and essential exsolved volatile-rich fluid phase in biotite granite have constrained it to host the lithium mineralization. The present area is characterized by three phases of Erinpura granitic activity. The leucogranite and the biotite granite are high-level, syn-metamorphic and syn- to post- kinematic, S-type granite generated by anatexis of Barotiya group supracrustals at different formation levels involving varying percentages of partial melting. Though supracrustals of the area were the source for both leucogranite and biotite granite, effective selective separation during anatexis has caused lithium phosphate mineralization in extremely well-differentiated leucogranite under absolute pegmatitic conditions along with essential coexisting exsolved volatile-rich fluid phase. For want of such suitable conditions the biotite granite could host only the tungsten mineralization. In Stewart pegmatite, only the upper intermediate zone contains Li mineralization, while simultaneously formed lower intermediate zone is devoid of mineralization due to the absence of exsolved fluid phase, essential for mineralization[15]. These obser-

vations also warn about uncertain chances of Li mineralization at deeper levels in the present area. The hornblende–biotite granite in this area seems to be devoid of any mineralization; however, further studies are underway to explore the possibility of its contribution in the metallogeny of the area.

Chemotherapy reduces human anti-filarial IgE response

M. K. Beuria* and Manoj K. Das†

Parasite Immunology Division, Regional Medical Research Centre (ICMR), Nandankanan Road, Bhubaneswar 751 016, India
*Present address: Department of Immunology, Central JALMA Institute of Leprosy (ICMR), Agra 282 001, India

The effect of diethylcarbamazine treatment on levels of IgE antibodies to infective larval (L_3) antigen of *Wuchereria bancrofti* and to a purified allergenic fraction (Sd_{30}) of *Setaria digitata* was followed up to 1 year in asymptomatic microfilaraemic patients infected with *W. bancrofti*. IgE levels increased transiently by day 15, followed by marked decline beginning at one month and persisting up to 12 month post-treatment. IgE responses to Sd_{30} underwent greater changes compared to L_3 antigen of *W. bancrofti*.

FILARIAL infection leads to an enhanced production of IgE antibodies in humans. The serum levels of specific IgE in different categories of *Wuchereria bancrofti* infection have been determined[1,2]. The highest level is exhibited by patients with chronic infection, followed by clinically normal people residing in the endemic regions and asymptomatic microfilaraemic carriers (AS). Immunologic changes in microfilaraemic (MF) patients associated with treatment with diethylcarbamazine (DEC), the drug of choice in filariasis, have been studied[3,4]. Chemotherapy brought about enhanced cellular immune responsiveness[5]. Changes in the antibody isotypes, especially IgE, have not received adequate attention. We report here the effect of DEC treatment in MF patients on levels of IgE antibodies to a purified allergenic fraction of *Setaria digitata* adult worms and to somatic infective larval (L_3) antigen of *W. bancrofti*. The allergenic fraction, which has been shown to cross-react serologically with L_3 antigen, exhibits IgE profile in filarial patients similar to that of L_3 antigen[6].

The study population was from a *W. bancrofti* endemic region of Orissa (Khurda district), India[2]. Eighteen microfilaraemic individuals of both sexes, aged 19–46 years (median 25 years), wishing to participate in chemotherapy were given DEC orally for 12 days at 6 mg/kg body weight under the supervision of a local medical officer. Blood samples were collected 15 days, 1, 3 and 8 months and 1 year after treatment. All the individuals were MF-negative when checked at 1 month post-treatment. L_3 antigens of *W. bancrofti* and the allergenic fraction of *S. digitata* (designated as Sd_{30}, molecular weight 30 kDa as determined by SDS-PAGE and G-200 Sephadex Gel filtration) were prepared as described earlier[2,6]. Serum IgE levels (at 1/100-fold dilution) were determined by ELISA by coating the plates with high antigen concentrations. The procedure was followed as described earlier[2].

All patients had measurable levels of IgE antibodies to both antigens before treatment. Changes in levels of IgE antibodies after DEC treatment relative to pretreatment levels are shown in Figure 1 and Table 1. A significant increase ($P < 0.05$) was noticed by day 15 in IgE response to Sd_{30} antigen. This was followed by a sharp decline, leading to values considerably lower than pretreatment values. The reduction observed at 1 month reached a nadir around 3 months after treatment and then increased progressively. The enhancement on day 15 was noticed in all patients except in four (two unaltered; two decreased). At 3 months, 15 patients exhibited a reduction in IgE response to Sd_{30} antigen, ranging from 72 to 100%; only two patients showed 50% and 20% drop. One patient did not exhibit any change after therapy. Levels of IgG antibodies to these antigens were, however, not affected (data not shown) by DEC treatment. All patients were found to remain amicrofilaraemic at 1 year post-treatment. It is of interest to note that IgE levels registered an enhancement at 1 year from the lowest values obtained at 3 months post-treatment.

Levels of IgE antibodies to Sd_{30} allergen underwent

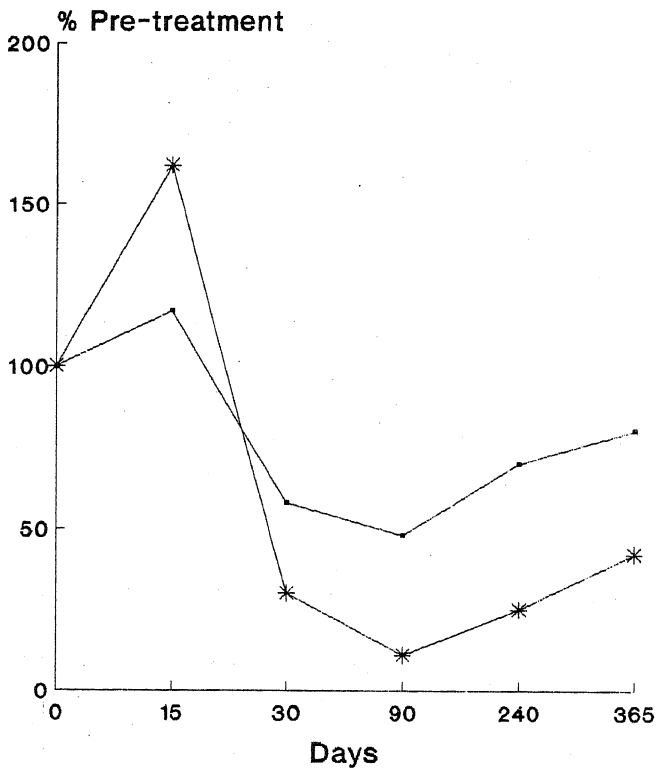

Figure 1. Antifilarial IgE levels after DEC treatment expressed as percentages of pretreatment for each patient. Each point represents the mean value of change with respect to pretreatment response for individual patients. (*) Sd_{30}; (o) L_3 antigen.

greater changes than those to *W. bancrofti* L_3 antigen. For example, the mean reductions in IgE response to Sd_{30} and L_3 antigen 3 months after treatment were 90% and 50% of pretreatment values, respectively. The lower reduction in L_3-IgE may be caused by persistent exposure to *W. bancrofti* larvae in the endemic region. It might also be possible that DEC treatment induces changes in IgE response to epitope(s) selectively present in Sd_{30} allergen. Earlier we have demonstrated that IgE response to these antigens is filariae-specific since people living in nonfilarial regions of Orissa exhibited negligible IgE levels[2,6]. IgE production is sustained in people in endemic areas by them being continuously exposed to the infection since clinically normal individuals of the endemic region have high IgE levels[2].

Considering the biologic roles of IgE antibodies in parasite infections, which vary from allergic disorders to conferring protection to hosts[7,8], the effect of drug treatment on IgE response is an interesting topic. The changes in specific IgE levels as reported here have not been characterized in human filariasis. The present report describes the response of the levels of IgE antibodies to two different antigens, L_3 stage of *W. bancrofti*, which initiates the infection, and a purified filarial allergen, Sd_{30}. Both the antigens exhibited diminished IgE production in treated patients over a course of time.

Immunologic changes following a two-year community trial of ivermectin treatment in Guatemala of patients infected with *Onchocerca volvulus* have been reported[9]. Enhanced parasite-specific IgE levels were noticed 6 months after treatment, which fell marginally below the pretreatment level by the second year. Although antiallergic action of DEC is well documented[10–12], the underlying mechanism was not known. The present results demonstrate clearly that DEC treatment diminishes the production of filarial IgE antibodies in humans and thereby contributes to decreasing allergic reactions.

The long-term monitoring of the study population will be helpful in finding out when IgE levels would be generated again in the DEC-treated patients.

The tissue-specific patterns of lactate dehydrogenase (LDH) for two species of the genus *Eryx* are reported and characterized utilizing sodium deoxycholate. LDH-1 is predominant in *Eryx conicus*, whereas LDH-3 and LDH-2 are observed in *Eryx johnii*. Sodium deoxycholate is a selective inhibitor of LDH-5 in *Eryx johnii*. Variations are observed in all the tissues between these two species and there is a variability of tissue LDH expressions within the species.

ISOENZYMES are multiple molecular forms of enzymes[1]. They can serve in taxonomic, genetic, phylogenetic and

evolutionary studies and help to solve many biological problems[2–5]. Lactate dehydrogenase (lactate: NAD oxido reductase, EC 1.1.1.27) controls the interconversion of pyruvate and lactate in the glycolytic pathway and thereby serves as an important source of the oxidized coenzyme (NAD) during periods of transient anaerobiosis. In most of the vertebrates, the isoenzymes of LDH are formed by the random self-assembly, *in vivo* and *in vitro*, of two different polypeptides A and B to form all possible isozymes, the two homopolymers A_4 and B_4 and the three heteropolymers A_3B_1, A_2B_2 and A_1B_3. The specificity of LDH polypeptide association is brought about by a combination of noncovalent forces[6,7].

LDH constitutes an excellent model system for the analysis of the problems of polypeptide assembly. Depending upon the organism and tissue, LDH can exhibit self-assembly[8,9], epigenetic modification of assembly[10–12], genetically controlled restriction of assembly[13–17] and directed assembly.

In this paper we report our investigation of the electrophoretic characteristics of LDH from two species of nonpoisonous snakes belonging to the genera *Eryx* of the family Boidae. Our aim is to determine the tissue-specificity of LDH subunit synthesis, to look for variations at the LDH locus and to compare isoenzyme patterns from the tissues of these two species.

Two species of snakes, namely *Eryx conicus* and *Eryx johnii*, were used in this study of the LDH tissue patterns. The snakes, all adults, used in this investigation were collected from different localities of Madras.

Twelve tissues, namely eye lens, brain, trachea, lungs, heart, liver, stomach, intestine, muscle, kidney, vertebrae and skin, were dissected from fresh specimen. Care was taken to see that the eye lens was free from contamination by the vitreous humour, retinal and choroid elements. Brain, lungs, heart and liver were washed thoroughly with ice-cold phosphate buffer of pH 7.4 as to render them free from traces of blood. Stomach and intestine were washed till they were free from their contents. Other tissues were washed thoroughly with phosphate buffer of pH 7.4. All the chemicals used in this study were purchased from E. Merck (West Germany).

The tissues were homogenized in iced condition with phosphate buffer of pH 7.4. The homogenates were centrifuged at 4°C at 25,000 × *g* for 30 min. The supernatants were used for gel electrophoresis.

A 5.5% polyacrylamide gel was used[18]. The current flow was adjusted to 2.5 mA per sample and run for 45 min with Tris–glycine buffer of pH 8.3. The gels were removed and stained. Inhibition studies were carried out using sodium deoxycholate.

The main aim was to determine the tissue-specificity of the LDH subunit synthesis in order to pinpoint the species specific biochemical markers and also to compare the LDH isoenzyme patterns in these two species.

The LDH patterns of the 12 tissues of *Eryx conicus* and *Eryx johnii* were observed and are shown in Figures 1 and 2, respectively.

The LDH isoenzymes of the snakes studied exhibited a net negative charge difference between isoenzymes. Therefore, the isoenzymes migrated more slowly towards the anode at pH 8.3.

In *Eryx conicus*, of the 12 tissues, 10 showed the predominance of only LDH-1 (B_4) isoenzyme – vertebrae and skin exhibited the four-isoenzyme pattern, LDH-5 (A_4), LDH-4 (A_3B_1), LDH-3 (A_2B_2) and LDH-2 (A_1B_3).

In *Eryx johnii*, except for lungs and vertebrae, all the other tissues analysed exhibited two isoenzyme fractions LDH-3 (A_2B_2) and LDH-2 (A_3B_1). Lungs and vertebrae showed the presence of three isoenzymes, namely LDH-4 (A_3B_1), LDH-3 (A_2B_2) and LDH-2 (A_1B_3).

The Rf values of these LDH isoenzymes were 0.18, 0.24, 0.28, 0.32 and 0.34 for LDH-5, LDH-4, LDH-3, LDH-2 and LDH-1, respectively, and are presented in Figure 3.

There was widespread resemblance among the LDH isoenzymes of these two species and a characteristic pattern of electrophoretic mobilities of LDH-5 (A_4), LDH-4 (A_3B_1), LDH-3 (A_2B_2), LDH-2 (A_1B_3) and LDH-1 (B_4). No difference was found in the LDH patterns of males and females. Each tissue exhibited a characteristic LDH pattern and the tissue-specific difference in the relative staining intensities of each LDH isoenzyme attributable to the quantitative variation in the proportion of the isoenzymes, which has been a function of a particular ratio of A and B subunits of each tissue. The staining intensity is shown in the densitometric scanning of the LDH isoenzyme of the two species, illustrated in Figures 4 and 5.

Sodium deoxycholate was used as a selective inhibitor of LDH-5 (A_4) isoenzymes to establish the subunit composition of LDH isoenzymes and to determine their genetic basis. There was a selective inhibition of A isoenzymes. The B subunits were resistant to the action of sodium deoxycholate. The characterization of the LDH isoenzymes was performed based on the literature[19].

The importance of this study lies in highlighting as to what extent the LDH isoenzymes play a role in the establishment of the basic tenets of biochemical taxonomy.

The differential regulation of gene function is a fundamental aspect of cellular differentiation. Isoenzyme (multiple molecular forms of enzymes) are ideal gene products for the analysis of differential gene function during embryogenesis and cellular differentiation[20–22].

Differences in the tissue pattern of enzyme locus expression were used to infer the extent of divergence among species. Some locus tissue expressions diverged markedly among species, while others were conserved.

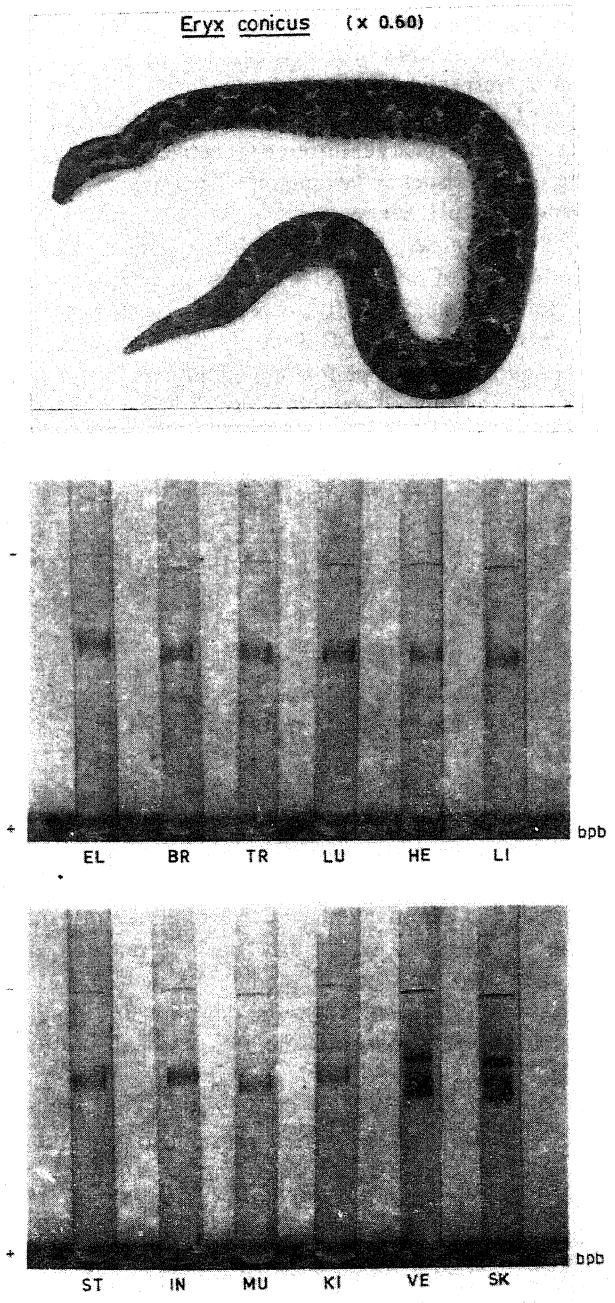

Figure 1. LDH isoenzyme profile of twelve tissues of *Eryx conicus*.

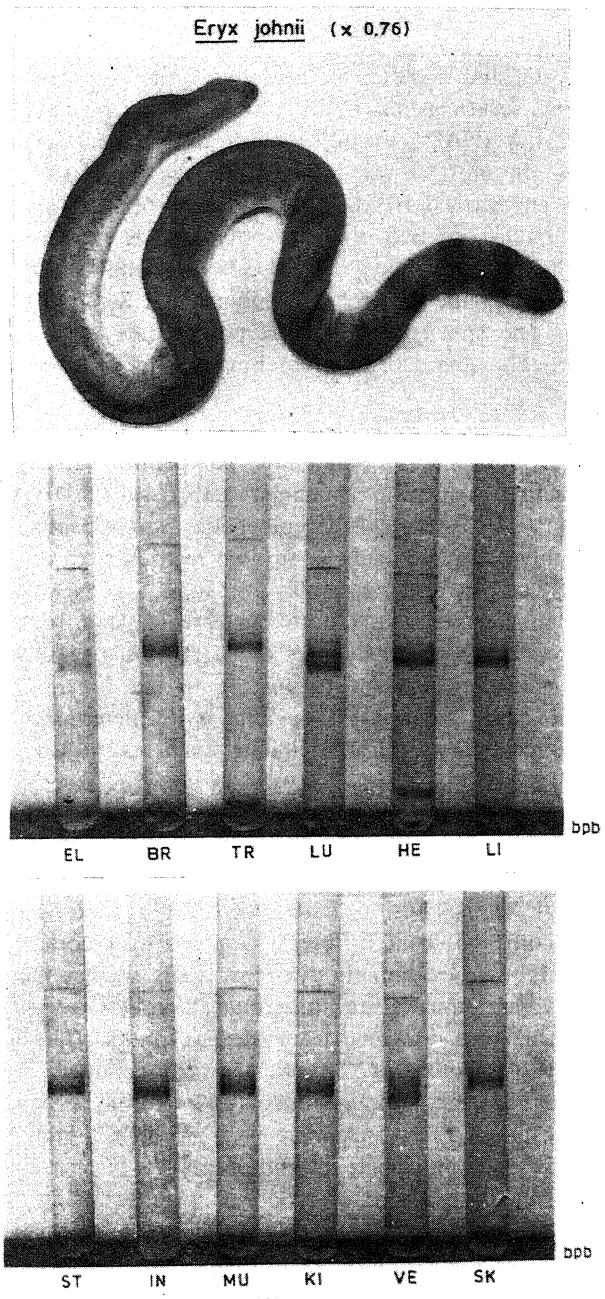

Figure 2. LDH isoenzyme profile of twelve tissues of *Eryx johnii*.

Differences in activity for a given enzyme among tissues, as well as for different enzymes within the same tissue, were sufficiently independent to permit each locus tissue expression of a species to be treated as a separate character. Statistically significant difference in levels of tissue enzyme activities among species were then used to construct a phylogeny. The phylogeny constructed using tissue enzyme expressional differences was similar to that based on enzyme structural difference and to one of morphologically based phylogenies[23].

The partial functional redundancy of L-lactate dehydrogenase (LDH) (EC 1.1.1.27) isoenzymes has permitted marked difference in the tissue regulations of their genes[24–29]. Both differential synthesis and catabolism contribute to the tissue patterns of LDH gene expression[30–34]. Tissue differences in the steady-state levels of LDH isozymes are probably due to mutations at sequences other than those coding for the respective isoenzymes. Such mutations could affect the number of enzyme molecules by altering one or more processes, ranging from transcriptions to catabolism, that is, by altering the regulations of gene expression in the broadest sense.

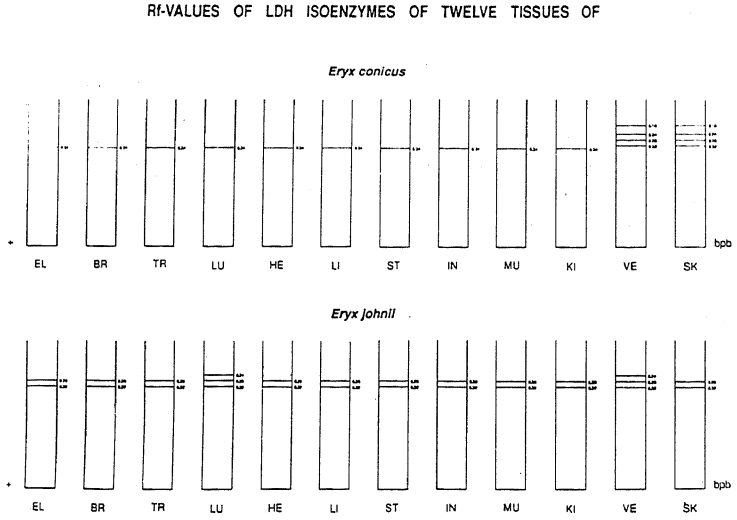

Figure 3. Rf-values of LDH isoenzymes of twelve tissues of *Eryx conicus* and *Eryx johnii*.

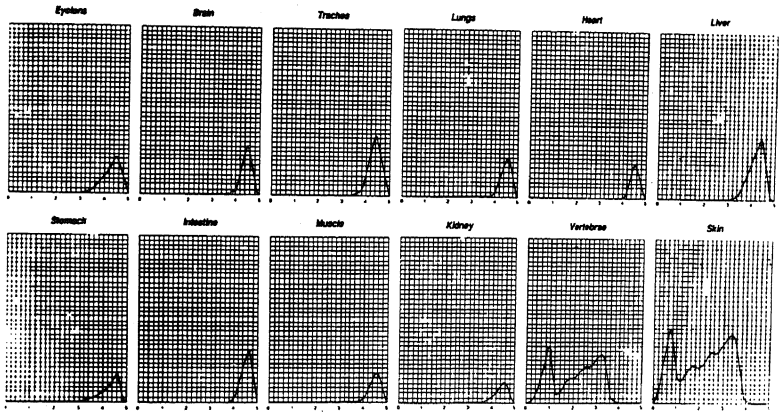

Figure 4. Densitometric scanning of LDH isoenzymes of *Eryx conicus*.

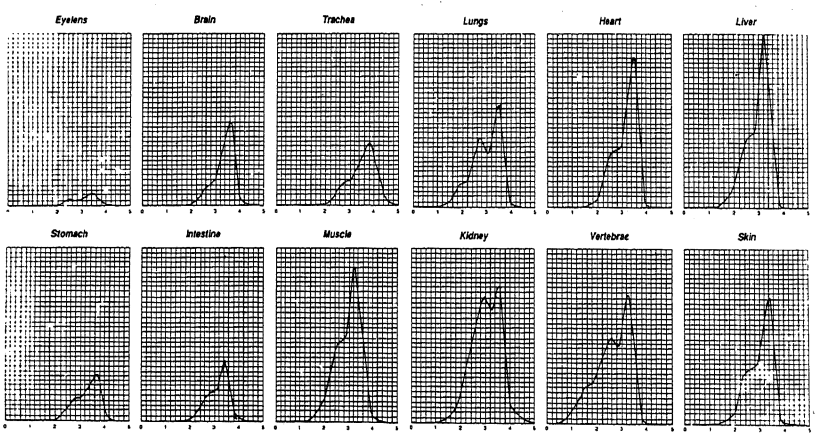

Figure 5. Densitometric scanning of LDH isoenzymes of *Eryx johnii*.

In several vertebrate species, regulatory genes that control the tissue expressions of the LDH-A and LDH-B genes have been detected[35–37]. These observations provide a basis for proposing that the species difference in the tissue patterns of LDH gene expression result from mutational changes at such regulatory genes.

Vertebrate LDH isoenzymes show one- to five-isoenzyme pattern and particularly the two-gene–five-isoenzyme model found in most of the mammals is the full array of LDH-A and LDH-B combination.

All tissues studied contained detectable amount of at least one of the five isoenzymes. Since there seems to be a homology between tissue distribution of isoenzymes in snakes and in other vertebrates, the same subunit designations A and B are used as applied to other vertebrates.

The predominance of LDH-1 (B_4) isoenzyme in all the tissues except vertebrae and skin in *Eryx conicus*, which was not observed in *Eryx johnii*, provides us a clue for identification of *Eryx conicus*.

The predominance of LDH-3 (A_2B_2) and LDH-2 (A_1B_3) in all the tissues except for lungs and vertebrae in *Eryx johnii*, which were not observed in *Eryx conicus*, gives a clear demarcation in establishing species identity.

Here with this authentic electrophoretic evidence, the LDH profile can be used as a specific biochemical marker for establishing species identity in the evolutionary scale of organisms at different levels of biological organization.

Lactate dehydrogenase of rat tissues was selectively inactivated by sodium deoxycholate[38]. Yet another highlight of this investigation is the discovery of sodium deoxycholate as specific inactivator of LDH-5 (A_4) isoenzyme in snake tissues.

Effect of addition of SO_2 on solid-state fermentation of apple pomace

V. K. Joshi, D. K. Sandhu* and S. Jaiswal

Department of Postharvest Technology, Dr Y. S. Parmar University of Horticulture and Forestry, Nauni, Solan 173 230, India
*Department of Microbiology, Guru Nanak Dev University, Amritsar 143 005, India

Addition of up to 150 ppm of sulphur dioxide (SO_2) in solid-state fermentation (SSF) of apple pomace by *Candida utilis* and *Torula utilis*, and 200 ppm in case of *Saccharomyces cerevisiae* generally enhanced the ethanol concentration, fermentation efficiency and decreased the reducing sugars. But 250 ppm and above of SO_2 proved inhibitory to all the yeasts tried. The titrable acidity remained similar except for a small increase in the treatment with 300 ppm of SO_2. The yeast count decreased after 200 ppm of SO_2. Bacterial and fungal contamination was the highest at 50 ppm and decreased after this level. The yeast counts at 150–200 ppm of SO_2 after 96 h of SSF of apple pomace were quite comparable with those obtained in the steam-sterilized treatment prior to inoculation. Addition of 150–200 ppm of SO_2 can be used as a practical alternative to sterilization in solid-state fermentation of apple pomace.

APPLE pomace is a waste from apple juice production and its disposal into the environment is a serious problem[1,2]. Its utilization by solid-state fermentation for ethanol[3,4] production or concomitant production of ethanol and animal feed has been reported[5]. To have effective solid-state fermentation, a more or less microbe-free environment is a prerequisite. There are always possibilities of contamination from atmosphere and container[6]. Compared to steam sterilization, use of chemicals for this purpose will be far cheaper. Preservatives such as potassium metabisulphite, sorbic acid and dimethyl-dicarbonate (DMDC) can be used as an alternative to pasteurization, filtration and sterilization[7]. In preservation of fruits and vegetable products KMS (providing SO_2) is used extensively[8] and its use in the solid-state fermentation would be cheaper than steam sterilization. Lack of any information on the use of SO_2 in the solid-state fermentation of apple pomace prompted us to carry out this study.

Three yeasts, viz. *Saccharomyces cerevisiae*, *Candida utilis* and *Torula utilis*, were grown in the yeast malt extract broth and used at the rate of 5% to initiate the solid-state fermentation. Apple pomace used was collected from 'hpmc' fruit-processing plant, Parwanoo (HP). Fresh apple pomace was used within 2 h of collection. Potassium metabisulphite (KMS) was added to the apple pomace. Six concentrations of SO_2 ranging from 50 to 300 mg/l (ppm) were tried. Various combinations of apple pomace after addition of SO_2 were not sterilized. A set without SO_2 addition served as a control. Fermentations were carried out in conical flasks. Before inoculation of yeasts in all the flasks and addition of KMS and ammonium sulphate, 1 g of sample from each flask was taken out aseptically for total microbial count, which was termed as 0 h reading. Fermentation was carried out for 4 days. In all the fermentations, the pH and moisture content were kept at the original level[5]. The fermented apple pomace was analysed for ethanol content by the method described by Caputi *et al.*[9]. The total microbial count was determined by the routine pour plate method[10]. Reducing sugars were measured by the DNS method[11], while total sugars were estimated after hydrolysis with acid prior to estimation. Titrable acidity was estimated as per the routine method[12].

Results in Table 1 reveal that in the case of fermentation of apple pomace by *Saccharomyces cerevisiae*, SO_2 concentration up to 200 ppm increased the ethanol production, after which it declined. However, in the case of fermentation by *Candida* and *Torula* ethanol productivity increased up to 150 ppm SO_2 only. In all the cases, 300 ppm of SO_2 proved to be inhibitory as shown by lowest ethanol production. Increasing SO_2 concentration decreased the sugar content in the medium. But the decrease was not exactly proportional to the increase in ethanol produced. Addition of SO_2 might have provided effective aseptic/anaerobic environment,

increasing the ethanol content, or could have maintained the ethanol level already produced in the medium by preventing its oxidation or its consumption by yeast cell after completion of fermentation, as has also been observed by Kargi *et al.*[13] using reducing agents such as cysteine and sodium thioglycollate in the ethanolic fermentation. Further, as the product of anaerobic mode of growth increased, concentrations of SO_2 higher than 150 ppm might have decreased the growth, and hence the metabolite, i.e. ethanol. The decrease of ethanol content at 300 ppm is clearly the result of toxicity of SO_2 to the yeasts. SO_2 after 200 ppm suppressing the fermentation is also supported by the findings of Terrell *et al.*[7], wherein 0.4 mM of SO_2 used in various combinations with other preservatives suppressed the fermentation. Fermentation of sugar by the yeast results in ethanol production and, to provide optimum conditions, naturally increases the efficiency of the process. It corroborates with the behaviour of the yeasts used in solid state fermentation of apple pomace.

The titrable acidity of the fermenting medium remained almost similar except for a slight increase in the pomace when 300 ppm of SO_2 was added. It indirectly shows that ethanolic fermentation took place satisfactorily in all the combinations except where 300 ppm of SO_2 was added. From the results it is also clear that trend in the acidities was almost similar in all the yeasts.

The results (Table 2) on the effect of different concentrations of SO_2 on microbial growth revealed that there is similarity in the effect of SO_2 on the growth of yeast, bacteria and fungi. It was found that 250 ppm of SO_2 was toxic to the yeasts (*Saccharomyces*, *Torula*, *Candida*) as there is low yeast count after 200 ppm of SO_2. A large number of bacteria and fungi were found in the case of yeast-inoculated sets of fermentation, indicating that complete sterility, as with steam sterilization, is not achieved with SO_2. With the increase in SO_2 concentration the bacterial and fungal count decreased, and the yeast count of the inoculated yeast increased. It is desirable from the ethanolic fermentation point of view. It has been reported[3] that natural fermentation of apple pomace also produces ethanol and addition of SO_2 might have prevented the activity of natural microflora and allowed the activity of yeast for better ethanol yield by solid-state fermentation. Microbial counts showed that the bacterial population was found maximum in the case of 50 ppm SO_2 in all the three inoculations of yeasts, and after 50 ppm there is considerable decrease in bacterial growth. Fungal growth was less than bacterial growth in all the concentrations of SO_2 tried. These findings suggested that the use of SO_2 can be made to achieve satisfactory solid-state fermentation of apple pomace.

Considering the ethanol yield, sugar content, titrable acidity, effect on different yeasts and their fermentation efficiency and microbial population, it is apparent that addition of 150–200 ppm of SO_2 is advantageous. Concentration of SO_2 higher than this may not be preferred due to the nonuniform effect on one or the other yeast in ethanolic fermentation of apple pomace by solid-state fermentation.

Analysis and significance of female reciprocal call in frogs

Debjani Roy, Bijoylakshmi Borah and Amarendra Sarma

Institute of Self-Organising Systems and Biophysics, North Eastern Hill University, Permanent Campus, Shillong 793 022, India

Female vocalization in frogs, feeble as it is, has often escaped the attention of researchers. Most of the work has focused on male vocalization and female phonotaxis experiments. The present study has for the first time compared in detail the temporal and spectral properties of the male advertisement and conspecific female reciprocal calls and focused on the role of female vocalization in the breeding biology of amphibians.

While studying anuran acoustic communication in the frogs of northeast India, female reciprocal calls given in response to the male advertisement call were recorded from *Rana erythraea*, *Rana limnocharis* and *Rana cyanophlyctis*. Once the female responds to the advertising males, more activity is observed in the breeding colony, involving mostly jumping around and across the responding female. The advertisement calls made by the male after the reciprocal call of the female have a higher intensity.

Comparative Fourier analysis of the female reciprocal call and the conspecific male advertisement call showed that the frequency domain of the male call is almost double that of the female call and accordingly there is a shift in the dominant frequency, whereas the spectral pattern consisting of a single or bimodal frequency distribution is common to both.

ANIMALS often produce vocal signals for communication[1–4]. In amphibians vocal signals have proved invaluable in studying systematic relationships[5–7] and the process of sexual selection[8–10]. Males of many amphibian anuran species produce species-specific complex sounds composed of numerous, closely spaced, often harmonically related components with predominant amplitudes that fall into distinct frequency bands, the locations of which are characteristic for each species. Male calls help to advertise their position, to defend their territories and to attract conspecific females to the breeding site, thus acting as an important determinant of mate choice[11–13]. Females recognize the calls of conspecific males, locate them within a chorus of the calling conspecific and heterospecific males and find a mate. Playback experiments have verified the importance of both the gross and fine temporal characters, as well as the spectral domain and spectral pattern of the call in a noisy acoustic environment[11]. Thus, the use of species-specific temporal and spectral character is one strategy for reducing heterospecific interference and maintenance of reproductive isolation[14–16].

Acoustic communication plays a significant role in the reproductive behaviour and breeding biology of amphibians[17]. Anuran vocalization has been classified according to the behavioural context in which the calls are elicited[18–20]. Most of the literature pertaining to anuran acoustic communication deals specifically with species-specific temporal and spectral characters of the male calls[11,14,21–23]. Although female vocalization had been reported as early as 1929, these reports were restricted only to the alarm, release and aggressive calls in *Rana silvatica*[24], *R. pipiens*[25], *R. esculenta*[26], *Colostethus inguanalis*[27] and *Eleutherodactylus coqui*[28].

Reciprocal call given in response to the male advertisement call was reported in the genus *Tomodactylus* based only on behavioural observations, with, no call recordings[29]. Heinzmann[30] working on *Alytes* sp., recorded two types of male calls – mating call and distress call. This work gives a brief description of the oscillogram for the reciprocal calls of the females, with no details of temporal and spectral characteristics. Female calling has also been reported in *R. ridibunda*[31] and *R. virgatipes*[32]. It is noteworthy to mention here that, though sketchy reports on female reciprocal calls existed[29] since 1957, in-depth study to look into the role of female reciprocal call in the breeding biology of amphibians has started only recently. A reason for this could be that the sensation of hearing for humans is most acute in the 2000–5000 Hz frequency range and the female calls occur much below this. Indeed, it is difficult to distinguish and record a female call, which is usually masked by the loud advertisement calls of the conspecific and heterospecific males in the vicinity.

While studying acoustic communication and related behavioural displays in the courting frogs of northeast India, we observed that females of *R. erythraea*, *R. limnocharis* and *R. cyanophlyctis* emitted reciprocal calls in response to male advertisement calls. Due to their feebleness and short call duration, these reciprocal calls would not have been noticed had they not been given in rapid succession, producing at times chirp-like calls, which attracted our attention. We then recorded and analysed the female reciprocal calls.

The calls were recorded during the active breeding period (May to August 1993 and 1994). In 1993 only behavioural observations were made and in 1994 the calls along with behavioural observations were recorded and analysed. The calls were recorded with a unidirectional AKG C451EB shotgun condenser microphone held approximately 40–60 cm away from the calling female. The calls were recorded with a professional SONY WM-D6C cassette recorder and stored on Maxell XLII cassette tapes. Sound pressure level was measured by playing back the isolated female calls on a Philips double cassette player DR920 with playback volume level fixed at 4 and the CYGNET 2021 sound pressure

level meter held approximately 60 cm away from the sound source.

Recorded acoustic stimuli were digitized via a Microsoft analogue-to-digital interface board on to an IBM PC and stored on diskettes. Oscillograms, sonagrams and mean spectra were prepared with a computerized Fourier analysis system (FFT) after passing through bandpass filters and printed with a laser printer.

R. erythraea are mostly arboreal in nature and hence their calls and reproductive behaviour were easier to observe and record in comparison to the calls of *R. limnocharis* and *R. cyanophlyctis*. The latter two species called mostly sitting on land on the edge of a swamp and while hovering on water surface, respectively. Besides, these two species were more easily disturbed, and swam deep into the water at the slightest disturbance. Calls of *R. erythraea* were recorded at Guwahati, Assam (200 m ASL; 91.5'E; 26.1'N). *R. limnocharis* and *R. cyanophlyctis* calls were recorded from colonies being maintained under near-natural condition in the froggery adjacent to the Institute at Shillong, Meghalaya (1515 m ASL; 90.7'E; 24.0'N).

The females of *R. erythraea* (Figure 1 *A*) are usually seen emerging and approaching the calling males after about 30 min of vocal advertisement by the male. When the distance between the calling male and the approaching female reduces to about 10 cm, the male which had been calling till then stops advertising. The female makes feeble reciprocal calls in response to the male advertisement call. This feeble call of the female at times continues up to 1 h, with several bouts of call. The interval between each bout varies from 2 to 5 min, short intervals at the beginning and long intervals towards the end of the call. Only after the female responds to the male advertisement call, the male which had stopped calling on the appearance of the female restarts calling with a higher intensity. Concomitantly, all the other neighbouring calling males also start calling at a higher intensity. More activity is seen amongst the calling males – mostly jumping from one place to another, but all jumps are confined around and across that female, which responded by giving the reciprocal call.

R. limnocharis and *R. cyanophlyctis* (Figure 1 *B, C*) females called while submerged in water, making the feeble reciprocal calls very difficult to hear and record and the behavioural displays difficult to observe. In both the species the females responded to the male advertisement calls. Once the reciprocal calls were emitted, the male calls were louder and more activity was seen amongst the males which were nearer to the responding female.

The reciprocal call of *R. erythraea* is low-pitched, lasting approximately 32 ms. The call sometimes has 3 to 4 subunits, each subunit not lasting more than 10 ms. The call is composed of about 22 pulses. The dominant frequency is at about 1048 Hz, with no harmonics, and the frequency domain extends from about 746 to 1229 Hz, the SPL being 77 dB (Table 1; Figure 1 *a*).

In *R. limnocharis* the calls lasted approximately 61 ms, with 45 pulses. The call had a single dominant frequency at about 1531 Hz, lacking harmonics. The frequency domain is comparatively small, extending from about 1300 to 1767 Hz, the SPL being 70 dB (Table 1; Figure 1 *b*).

In *R. cyanophlyctis* the call duration was approximately 20 ms, composed of 20 pulses, having constant interpulse interval. The frequency distribution was bimodal, with dominant frequency at about 740 Hz and its second harmonic at about 1433 Hz. The frequency domain extends from about 496 to 1746 Hz, the SPL being 65 dB (Table 1; Figure 1 *c*).

Comparative spectral analysis of the female reciprocal calls with male advertisement calls of *R. erythraea* (Roy, unpublished), *R. limnocharis* and *R. cyanophlyctis*[7] shows that female calls are much shorter in duration, with comparatively more pulses, resulting in reduced interpulse interval and pulse overlap. There is a shift in the frequency domain towards the lower range (almost half) in all the three female reciprocal calls, resulting in a shift of dominant frequency as well. Interestingly, in spite of the spectral frequency shift to the lower range, the spectral pattern along with the envelope curve remains unchanged. Like their male counterparts, there is only a single dominant frequency in *R. erythraea* and *R. limnocharis* and bimodal frequency distribution in *R. cyanophlyctis*.

Female vocalization due to its feebleness and the secretive nature of the females has often escaped the attention of researchers. Most works done till now have been on male vocalization and female phonotaxis experiments. This study has for the first time focused on the role of female vocalization in the breeding biology of the amphibians and demonstrated that the female reciprocal calls seem to act as a 'catalyst' for the enhancement of the reproductive activity of the breeding colony.

The feebleness of the call may be due to various reasons: (a) The bigger size of the females compared to the males[5,33]. (b) The absence of vocal sacs in the females; the expandable pouch-like vocal sac present only in the males acts as a sound resonator and radiator[1,19,34]. However, little evidence exists to support this hypothesis and it is now being contemplated that the vocal sacs in the males may have a 'variety of mutually nonexclusive functions'; this is still being worked upon[35,36]. (c) The differences in the structural morphology and tension of the musculature of the vocal cords and larynx and also the tension of the trunk muscles[37–40]. A comparative study on the morphology

Table 1. Comparative analysis of female reciprocal calls and male advertisement calls of *R. erythraea*, *R. limnocharis* and *R. cyanophlyctis*

Species	No. of calls per species	Call duration (ms)	Pulse number	Frequency (Hz)		
				Dominant frequency	Lower limit	Upper limit
R. erythraea						
Female	14	32 ± 9	22 ± 9	1048 ± 105	746 ± 126	1229 ± 114
Male	15	224 ± 4	25 ± 1	2459 ± 42	1495 ± 23	3724 ± 31
R. limnocharis						
Female	14	61 ± 27	45 ± 7	1531 ± 204	1300 ± 224	1767 ± 213
Male	40	503 ± 101	80 ± 13	2144 ± 1254	1576 ± 87	2685 ± 115
R. cyanophlyctis						
Female	12	20 ± 4	20 ± 6	740 ± 36 1433 ± 84	496 ± 57	1746 ± 4
Male	34	615 ± 155	7 ± 1	1651 ± 43 3192 ± 213	1163 ± 124	3907 ± 42

Spectral data on the male advertisement call of *R. erythraea* (Roy, unpublished); spectral data on *R. limnocharis* and *R. cyanophlyctis* from ref. 7.
Values are mean ± SD.

as well as the kinematics of the vocal sacs of the conspecific male and female vocal apparatus is necessary to come to a definite conclusion in this matter.

Bioacoustic analysis of amphibian vocalization has emphasized the species-specific temporal and spectral characteristics of the calls. Shift in the temporal pattern occurs which helps avoid acoustic interference and increase the attractiveness of the call is well known[41,42], but shift in the spectral frequency domain has not been reported. The present study in the three ranid species shows that the frequency domain of the male call is almost double that of the female call and accordingly there is a shift in the dominant frequency, whereas the species-specific spectral pattern of having a single or bimodal frequency distribution remains unaltered (Figure 2). The result of this comparative analysis raises an important question – should the spectral pattern, due to its unaltered species-specific nature, be considered more important than the spectral domain for species identification on the basis of bioacoustic analysis of frog calls?

Yttrium-, niobium- and zirconium-rich rhyolite dykes of Dhorio Nes area, district Jamnagar, Gujarat, India

P. B. Maithani, Rahul Banerjee, Navin Goyal, S. Ramachandran and Rajendra Singh*

Atomic Minerals Division, Sharada Building, R. V. Desai Road, Baroda 390 001, India
*Atomic Minerals Division, AMD Complex, Begumpet, Hyderabad 500 016, India

Anomalously high contents of Nb (818 ppm), La (173 ppm), Y (305 ppm) and Zr (> 1000 ppm) are reported for the first time in the rhyolite dykes/veins spatially associated with the Deccan basalts in Alech hills around Dhorio Nes, district Jamnagar, Gujarat. The enrichment of these elements is due to influx of alkalies and volatiles in rhyolites emplaced along the western continuity of E–W-trending Son–Narmada rift.

THE Deccan Traps, covering about one-sixth of India's total land surface, comprise mostly of tholeiitic basalt. Acidic, alkalic and mafic alkalic rocks are found in the western part of the basalt plateau in western India in parts of Kutch, Saurashtra, Lower Narmada Valley and Bombay coast.

The Saurashtra region of Gujarat is known for a number of acid igneous rock complexes along the western extension of the Son–Narmada lineament. These include the Alech–Barda hills, Osham hills, Girnar hills and Chogat–Chamardi hills[1]. These acidic rocks developed as an independent magma suite with rhyolite as a predominant rock type within the complex[2,3], or as an end product of differentiation[4].

In Alech–Barda hills, the acid igneous rocks comprise pitchstone, rhyolite, granophyre and diorite. The rhyolites occur as dykes and veins within the basalt, and also as flows of rhyolitic crystal tuffs. Two prominent pink- to buff-coloured, highly fractured E–W-trending rhyolite dykes were noticed in the south and southwest of Dhorio Nes (69°59′44″ : 21°48′27″, Toposheet no. 41 G/13) in the Alech hill area, showing higher than background radioactivity (Figure 1). They extend over a length of 500 m with width varying from 10 to 30 m. They consist mainly of quartz, sanidine and glass along with some opaques and exhibit vitrophyric texture. The groundmass in the rhyolites is essentially composed of a glassy material along with crystallites of feldspars. The chemical data of these rocks along with the data of Pavagarh and Amreli rhyolites and the general abundance in rhyolites is given in Table 1. The samples show normative corrundum, peraluminous ($A/CNK = 1.52$), miaskitic ($AI = 0.64$) nature and enrichment of potash over soda.

*Of trace elements in basalt[10].

Unusually high content of Nb (818 ppm), La (173 ppm), Y (305 ppm), Sn (36 ppm), Zr (> 1000 ppm, average 2090 ppm for 2 samples – XRF analysis) and U (35 ppm) were recorded in the rhyolite dykes ($n = 14$) of Alech hills around the Dhorio Nes area of Jamnagar district, Gujarat (Figure 1), which is higher than the general abundance of these elements in acidic rocks. The anomalous content of these elements in the rhyolite dykes of Dhorio Nes is due to the presence of brownish-red- to blood-red-coloured, tetragonal- to square-shaped xenotime and rutile, in addition to the monazite and ilmenorutile, as observed under the microscope. Besides, zircon is also identified by X-ray diffraction studies of heavies separated from rhyolites. The detailed mineralogical studies of slime and light fraction are under progress using electron probe micro analyser (EPMA).

The upper mantle source region may have been enriched or metasomatized to give rise to basalts with anomalous values (Table 2), which in turn fractionated to minor rhyolites with anomalous Y, Nb and Zr values. The Narmada–Son rift, which has been reactivated several times during the geological history, probably acted as a locale for the concentration of these trace elements. The mantle-derived CO_2-rich fluids from this rift also contributed to the trace element pattern observed in the rhyolites. It is pertinent to mention here that there are many carbonatite–alkaline complexes along the Narmada–Son rift[5].

Significant amounts of U, Nb, La, Y and Sn in rhyolites of Dhorio Nes makes Alech hills, a possible potential area for exploration of these metals. Detailed work on the find is underway and will be published shortly.

Department of Chemistry, Dayalbagh Educational Institute, Dayalbagh, Agra 282 005, India
*Present address: Department of Chemistry, University of Allahabad, Allahabad 211 002, India

Geochemical monitoring of atmospheric heavy-metal pollution is so far limited to the use of peat, ice deposits and aquatic sediments as sample type. These systems are open, dynamic and easily affected by climatic variations. In contrast, bricks, which are more compact, can act as a better geochemical monitor. Heavy-metal (Cu, Zn, Ni, Cr, Pb) analysis in scores of soil and baked/unbaked brick samples collected from a large area in and around Agra City indicates approximately similar flux in soils and bricks and insignificant fractionation during brick construction of these metals. The concentration of analysed metals in the core of bricks remained unaffected even by substantial amounts of acidic/alkaline rain under natural conditions. Thus, the feasibility of a new, hitherto untested, concept of bricks acting as a geochemical monitor of atmospheric heavy-metal pollution has been systematically explored.

ATMOSPHERIC heavy metals interact with terrestrial environment continuously. From the standpoint of mass, their major amount is absorbed by plants and soils[1,2]. Chronological changes in the heavy-metals flux of terrestrial objects, mainly as a result of atmospheric depositions, reflect the impact of human growth on accumulation of toxic metals on the global ecosystem over the years. Studies of the practical applications of geochemical monitoring have been carried out mainly in Northwest Europe, North America and the remote polar regions, particularly in relation to the historical aspects of pollution. Records from peat deposits and lake sediments in Europe document the growth and development of industry there over the last 2000 years[3–8]. Reconstructed historical deposition rates demonstrate the severity of pollution in urban areas of northern Britain in the eighteenth and nineteenth centuries, whereas analysis of recent sediments reveals a variable pattern of present-day pollution, with some areas experiencing increasing levels of deposition and others decreasing ones[9–11]. In North America deposition records reveal a much shorter history of atmospheric pollution and document the rapid spread of heavy metals during the mid and late nineteenth century, both on a local and on a regional scale[12–16]. For most of the other parts of the world, no such detailed information exists and studies are limited mainly due to lack of suitable sample types, where the original heavy-metals compositions remain preserved unperturbed over long periods of time. Peat, ice deposits and aquatic sediments, most extensively used so far in monitoring the atmospheric depositions of heavy metals are open, dynamic systems and can be easily affected by climatic changes.

The use of baked bricks in the construction of buildings is an age-old practice all over the world. The commercial process of construction and baking of bricks has not changed much over the years, and the stuff used in brick manufacture is primarily soil derived from the top 1–1.5 m of the earth, a portion where atmospheric depositions of heavy metals are most likely to be retained[2]. The temperature of bricks during commercial baking rises up to $\approx 700^{\circ}C$, at which most of the soil-bound heavy metals possibly remain intact in soil matrix. Hence, bricks of any specific period of time, if kept preserved from the effects of rain and radiations, can be regarded as representative samples of soil of that period, from the viewpoint of heavy-metals composition. Bricks, which can be effectively used for chronological monitoring of atmospheric heavy-metal depositions in soil and which are likely to be better than so far used sample types, viz. ice, peat and sediments, have eluded the attention of researchers till now. This paper deals with a systematic evaluation of the effectiveness of bricks for this purpose.

From an approximately $10^3\ km^2$ area in and around Agra City the following samples were collected: (i) baked and unbaked (65 each) brick samples from

different brick kilns; (ii) bulk soil samples from 35 places after removing the top 7–10 cm layer of the earth; (iii) bulk soil samples from 5 places (wide apart) after every 30 cm depth (up to 1.5 m). The soil samples were air-dried (at 35°C), mildly ground and mixed well; the texture of few representative samples was determined by the wet sieving procedure. The inner core (≈ 50 g) of each brick sample was taken out by removing the external layers in a mechanical cutter and ground to powder form avoiding external contaminations. The grinding was done till the final texture of the brick powder was almost identical to the texture of the soil. The acid extracts of powdered brick and soil samples, generated under mild, semidrastic and drastic acid treatments (detailed below), were quantitatively analysed for Cu, Zn, Ni, Cr and Pb using the standard methods[17], employing Perkin Elmer 2380 flame atomic absorption spectrometer at appropriate wavelengths.

For mild treatment the sample (6 g) was treated with 10 ml HCl (3 M) and 10 ml HNO_3 (3 M) for 24 h and then boiled till the volume was reduced to 3–5 ml. After adding 20 ml of 0.01 M HCl, the contents were further heated for 15 min, cooled, filtered through acid-washed Whatman 42 filter paper and the extract was collected for analysis.

For moderate treatment the sample (6 g) was treated, in a teflon vessel, with 10 ml HCl (6 M), 10 ml HNO_3 (6 M) and 1 ml HF (48%) for 24 h, followed by slow heating at 45–60°C till the volume was reduced to 3–5 ml. In order to ensure the complete removal of unreacted HF, 20 ml of 0.1 M HCl was added and the contents were further heated at elevated temperature (65–80°C) till the volume was again reduced to 3–5 ml, which was then transferred to a glass vessel using 20 ml of 0.01 M HCl as the washing solution. The contents were boiled till the volume was reduced to half, cooled, filtered as above and the extract was collected.

For drastic treatment the sample (6 g) was treated, in a teflon vessel, with 5 ml HCl (12 M), 5 ml HNO_3 (16 M) and 10 ml HF (48%) for 24 h and then heated gently at 45–60°C till the volume was reduced to 3–5 ml. Adding 5 ml each of HCl (12 M) and HNO_3 (16 M), the contents were further heated at 65–80°C till the volume was again reduced to 3–5 ml. At this stage the complete removal of unreacted HF was ensured. Using 20 ml of water as the washing solution, the contents were transferred to a glass vessel, boiled till the volume was reduced to half, cooled, filtered as above and the extract was collected.

The final volume (after washings) and pH of all the extracts were adjusted, respectively, to 50 ml and 3–4 by suitable additions of HCl (0.01 M), NaOH (0.01 M) and water. Metal concentrations were determined in reagent-blank extracts also and the values were subtracted from the main data. The extract samples were stored in acid-washed polythene bottles before analysis. Double-distilled deionized water and AR grade reagents were used throughout the study.

The textures of 20 randomly chosen samples each of powdered bricks and soils were determined (Table 1). The results indicate approximate similarity of the two systems. The average concentrations of Cu, Zn, Ni, Cr and Pb in soil and baked/unbaked brick samples, as determined by the analysis of extracts generated under mild, moderate and drastic treatments, are presented in Table 2. Table 3 shows the results of some laboratory experiments to observe the effects of rain (of varying pH) on heavy-metal concentrations in the core of baked bricks while the bricks are exposed to natural conditions at 30–35°C.

Soil concentrations of metals are in the range of earlier reported values of some Indian soils[18]. Extracts of soil and brick samples generated through mild and moderate extraction procedures show a wide variation in their metal concentrations, whereas drastic-treatment data indicate approximately similar concentrations of metals in soils and baked/unbaked bricks. It is also clear that except for Cr, which shows a slight increase, the concentrations of the remaining four metals in soils of the studied area are not significantly changing with depth (ranging from 0.1 to 1.5 m). Metal concentrations in the core of baked bricks remain unaffected by substantial amounts of acidic/alkaline rain and radiations. However, prolonged exposure of bricks to these results in some changes.

The close association of soil-bound heavy metals with soil matrix, largely composed of silicates, is well known and might further increase during brick construction, depending upon the maximum temperature reached during baking. Hence, determination of metal concentrations in soil and brick extracts depends on the effectiveness of the extraction technique in breaking/dissolving the soil matrix. The wide range of fluctuations in data (Table 2) under mild and moderate treatments indicates inadequacy of extraction procedures in breaking the matrix, and only the drastic treatment, with 95–100% dissolution of the sample, seems to give satisfactory results.

The temperature of bricks during commercial baking

rarely exceeds 700°C, and the existing vaporization/dissociation temperature data[19] of different metal salts suggest that the major amount of most of the soil-bound heavy metals possibly remains intact in the soil matrix at this temperature. This contention is supported by drastic-treatment results (Table 2), indicating approximately similar concentrations of metals in soils, unbaked bricks and baked bricks. The negligible fractionation of metals during brick construction and to some extent insignificant effect of rain and radiation on heavy-metal concentrations in the core of bricks (Table 3) make it feasible to consider bricks as representative samples of the parent soil from the viewpoint of heavy-metals composition. The compactness and easy availability are other distinct advantages in using bricks as a geochemical monitor, rather than ice, peat and sediments.

From the viewpoint of plant nutrition, soil layers at 0.1–1m depth from the top are the most important because mineral-absorbing zones of plant roots generally lie in this region. Changes in concentrations and mobility of metals in this region have a direct consequence on the living systems, and the entry of some toxic metals in the food chain cannot be ruled out. Incidentally, in brick construction also, this portion of soil is mainly used. Thus, bricks act not only as representative samples of the parent soil but also as samples of biologically most important layers of the top soil.

Heavy metals enter the soil through many sources, viz. atmospheric depositions, agricultural activities, industrial and local emissions. By analysing bricks of different ages derived from interior and well-preserved portions of old buildings/monuments for different metals and presenting the data on time scale, it is possible to trace the past and present accumulation rates of metals in soils of a particular area. Moreover, with the help of statistical tools the identification of probable sources of these metals and the estimation of their contributions

is possible. Analysis of samples collected from remote areas, where local effects are negligible, will reflect the rates of global inputs through atmospheric depositions. In contrast to approximate and lengthy stratigraphic, biostratigraphic, radiometric and geomagnetic techniques used for dating aquatic sediments, peat and ice deposits, the dating method for bricks is limited to determining the construction time of the building from which the brick sample is derived. Most parts of the world have witnessed much of the industrial and urban growth only during the last 200 years and brick samples of this duration can be easily obtained and accurately dated. Further, bricks being heavy construction material are never transported over long distances due to economic reasons and remain representative samples of soil of the area of their collection.

Though our study has shown both bricks and soil as true representatives of each other in respect of concentrations of all the five metals analysed, this trend, far from being general, is bound to be dependent on soil characteristics of the particular area and minor variations in brick-making process from place to place. In the event of certain metals showing considerable fractionation during brick construction, the ratio x ($x = [\text{metal}]_{\text{soil}}/[\text{metal}]_{\text{baked brick}}$) may be determined by analysing a large number of present-day samples. With some approximations, the average values of x (for different metals) can be utilized in calculating metal concentrations in soils of different ages from the metal concentrations data of old bricks. The present study, thus, leads to the following conclusions:

1. From heavy-metal concentrations viewpoint, except for few volatile metals, bricks derived from interior and well-preserved parts of buildings can be regarded as representative samples of the parent soil.

2. To some extent, rains and radiations do not change metal concentrations in the core of bricks.

3. Due to greater compactness and easy availability of samples, bricks are likely to be a better geochemical monitor than ice, peat and sediments and can be used in geochemical monitoring of heavy-metal pollution. However, this technique has to be used judiciously for monitoring atmospheric heavy-metal pollution of soil in historical times due to anthropogenic activities in the past, because the parent soil of a brick collected from a specific area may have inherently high heavy-metal content due to natural causes also.

Finally, it should be stated that the conclusions derived here are based on the study restricted to the city of Agra and its suburbs only. More such studies, in other parts of the world, are needed to understand the exact potential of bricks as a geochemical monitor.

1995 has been declared by UNESCO as the International Year For Tolerance. The principal aim of this initiative is to promote among humankind at least tolerance and understanding, if not love, of diversity and pluralism in human communities in terms of religion, language, ethnicity, skin colour, gender and political belief. The Director-General of UNESCO, Federico Mayor, mentioned in a lecture at New Delhi in May 1995 that fostering appreciation and tolerance of human diversity is the best way of commemorating the 125th birth anniversary of Mahatma Gandhi. Gandhiji's gospel of nonviolence was based on his conviction that nonviolence cannot be practised in compartments – it has to be total, encompassing all manifestations of life. Thus, he once mentioned that it will not be possible to be nonviolent to nature if we are going to be violent to each other. He was convinced that the alternative to *sarvodaya* was *sarvanasha*.

The Global Biodiversity Convention at Rio de Janeiro in 1992 designed to protecting flora, fauna and microorganisms will not help in achieving its purpose, unless there is an equal commitment to preserve, respect and nurture human diversity. It is worth repeating this central message of Gandhian thought and action at a time when violence is growing in the human heart. This trend is getting reflected in many ways – starting with violence to oneself (through drug addiction and AIDS) and violence to whole religious or ethnic groups as is happening in the former Yugoslavia or in Rwanda. The term 'ethnic cleansing' is now being used in the mass media without evoking horror and universal condemnation. T. N. Khoshoo has reminded us through this well-written book the beauty, simplicity and eternal relevance of Gandhiji's views on different aspects of human development. The book indicates how the four major ills of contemporary human developmental pathways could have been avoided had policy makers in all countries followed the Gandhian approach and methods of planning. It would be useful to refer to these briefly, since reexamining them and adapting them to present-day conditions could pave the way to achieving the harmony we now seek with nature and with each other.

The first serious malady of today's pattern of economic growth is the increasing rich–poor divide in economic well-being. Over 84% of the world's annual income now goes to 20% of the world's people. Another 20% get only 1.4% of the global annual income. One billion women and men live on a daily per capita income of less than one US dollar, while another 2 billion earn less than 2 US dollars per day. Everyday 68,000 babies are born to families living on less than one dollar per day. The Gandhian recipe to such gross inequity consisted of three seminal ideas. First, the promotion of sustainable life-styles would lead to curbing greed and meeting the essential needs of everyone. Second, the adoption of democratic decentralization in planning would lead to addressing the minimum needs of every child, woman and man. Third, the adoption of the concept of trusteeship by the well-to-do with reference to their surplus wealth will result in the promotion of symbiotic social contracts between the rich and the poor. For example, if the 20% of the global population now enjoying 84% of its annual income will regard themselves as trustees and not owners of their enormous income and will adopt sustainable life-styles and share their wealth with the poor, the funds needed to overcome extreme poverty and deprivation will be readily available.

Secondly, the present pathways of development are causing serious damage to the environment, resulting often in irreversible harm to the rights of the unborn for a healthy and productive life. Khoshoo has explained in detail the Gandhian approach to protecting our life support systems of land, water, flora, fauna, forests and the atmosphere. Conserving nature and natural resources and using them in an ecologically sustainable and socially equitable manner constitutes the core of the Gandhian approach to environment protection.

A third serious malady of present-day developmental paradigm is the phenomenon of jobless growth, i.e. GDP increases but employment opportunities diminish. Gandhiji's approach to promoting sustainable livelihood security was the creation of eco-jobs based on organic recycling, garbage and sewage utilization, generation of wealth from wastes, ecological farming, value–addition to natural products through village-level agro-processing and promotion of self-reliance at the village level to the extent possible. Decentralized production supported by a few key centralized services will help to convert the concept of sustainable livelihoods for all from rhetoric to reality. The *charkha* was the most elegant and effective symbol Gandhiji used to stress the need to convert cotton into cloth at the local and even household level, rather than sending cotton abroad (as was happening in the 1930s) and importing textiles. To the slogan 'export or perish' the Gandhian answer will be 'import less and live', since the present pattern of exports based on an unsustainable exploitation of environmental capital stocks would result in 'export and perish'.

Finally, the most serious of present-day ills is the spread of violence. Mini conflicts are replacing mega conflicts. Failure to integrate the principles of equity and ethics in the present developmental paradigm is a major reason for the spread of a culture of violence. Economic structural adjustment dictated by international financial institutions enhances the deprivation and misery of the poor. These adverse effects are being addressed through recipes such as structural adjustment with a human face and safety nets for the poor. Gandhiji considered economic equality an essential condition for nonviolent independence. He once mentioned that a technological society has two choices. First, it can wait until catastrophic failures expose systemic deficiencies, distortion and self-deceptions (as is happening now). Alternatively, a culture can provide social checks and balances to correct for systemic distortion prior to catastrophic failures. The alternative approach involves adopting *antyodaya* (attention to the poorest person) as a means to achieving *sarvodaya* (well-being of all). It also involves gender equity, with women being accorded the same status and attention as men in all spheres of human development. Thus, the structural adjustment we need now in the world is adjustment to sustainable life-styles and to the internalization of the principles of equity, both in gender and economic terms, in our daily life.

Khoshoo and the Tata Energy Research Institute have rendered great service to

contemporary development debate by bringing out this collection of Gandhian principles in the areas of environment and development. At least in vocabulary, the Gandhian approach is being recapitulated in the declarations of the recent UN Conferences. If a stripe review is undertaken of the declarations made at the Children's Summit in New York (1990), the UN Conference on Environment and Development, Rio de Janeiro (1992), the Conference on Human Rights, Vienna (1993), the Conference on Population and Development, Cairo (1994), the UN Social Summit, Copenhagen (1995) and the Fourth World Conference on Women to be held in Beijing in September 1995, we will find a striking resemblance between many of the statements contained in Khoshoo's book and those embodied in the international declarations. Converting the Gandhian development strategies and value systems from theory into practice is thus an idea whose time has come.

Recent Trends in Aerobiology, Allergy and Immunology. A collection of Plenary Lectures and Contributory Articles. Ed. S. N. Agashe. Oxford & IBH Publishing Co. Pvt. Ltd., New Delhi. 1994. 315 pp. Price: Rs 750.

Aerobiology is the study of airborne particles of biological origin, their sources, liberation, deposition and impact on agriculture/human health. The presence of these particles in the atmosphere is influenced by environmental and climatic conditions. The emphasis of aerobiology has shifted from one aspect to another. During the last few decades, aerobiology has assumed importance because of its role in diagnosis of allergic disorders. The role of pollen in allergic rhinitis was shown by Charles Blackley as early as 1873. Since then, a lot of work has gone in to show the relationship between aerobiology and allergology. Various systematic studies were conducted on the presence of pollens and fungal spores in the atmosphere and their effect on human health. The book under review consists mainly of papers presented at the 5th International Aerobiology Conference held at Bangalore in August 1994. The 20 topics cover diverse areas, mainly of aerobiology related to allergy, except for a few topics dealing with the usefulness of aerobiology in forensic sciences, solar radiation, polymorphic light eruption, and paradox and placebo of medicine in the 21st century.

Brown in his article has brought out the historical relationship between aerobiology and allergy, while John Lacey in his article has emphasized the other aspects of aerobiology and given various priorities for aerobiological research. Other articles on pollen calendar and the environmental influences on the allergenicity of pollens give a lot of information in this area. A few articles on fungal spores, including alternaria, and their effect on human health and foods are worth reading. The pollen allergy in India has been dealt with in great detail. Also there is an interesting article on latex allergy which warns of the severe risk for workers in the manufacture of latex products. The house dust mite is a known source of allergen which has been shown to be a principal factor responsible for early morning asthmatic attacks. The book has two articles on this topic: one on the current studies of research on dust mite in India and the other on the use of mite allergens for immunotherapy. Until a few years ago, insects were not considered as major allergenic source. However, during the last few years insects as aeroallergens have been conclusively established and the review of this topic is very informative. The book also covers molecular characterization of allergens and the current studies in immunotherapy.

The wide range of fields covered in this volume illustrates the importance of aerobiology. However, the topics are not arranged with any specific aspect in mind. There is scope for improvement by reducing the typographical errors and improving the quality of paper and the production of photograhs. Even though the references quoted by various authors are comprehensive, there are serious deficiencies concerning recently published literature. The inclusion of subject index and abbreviations used in the book could have added to the quality of the book.

In spite of all deficiencies the book gives a lot of current information on various aspects of aerobiology and is an important edition for the students working in this field. The book is not priced but I hope it will be within the reach of any Indian student and will be inspiring to the research workers in aerobiology.

***In vitro* Culture and its Applications in Horticulture.** H. Vidalie (coordinator). Oxford & IBH Publishing Co. Pvt. Ltd., New Delhi. 1995. 231 pp. Price: Rs 360.

In vitro culture of economically important crop species is a key area of applied research in biotechnology. Micropropagation technology is the best example of direct applications of research outcome in different plant species. During the past decade many '*in vitro*' culture techniques have been scaled up to commercial level and now various commercial companies are producing a large number of propagules of selected rare clones of various plant species, among them ornamental and horticultural crops being the main candidates. In these species full-fledged technologies are standardized and are being commercially exploited. A lot of information is available in the form of research and review articles. There are many books available on the *in vitro* culture of ornamental, horticulture, woody perennials, and important crop species. The book under review is an addition to the voluminous literature already existing. The book is contributed by a team of teachers, researchers and practitioners of commercial tissue culture from Angers, France.

This book covers the various aspects of *in vitro* culture application, main methods of laboratory set-up, media preparation, the choice of explant, and physiological phenomena related to *in vitro* culture. The genetic aspect of tissue-culture-raised plants has also been considered.

The first part of the book is on the history, basic physiology of differentiation and redifferentiation, the role of hormones, the choice of explant as per age, size, position and response in culture. One of the chapters is on nutritional aspects, such as chemical composition of the medium and its physical characteristics (e.g. liquid/solid environment, media and gaseous exchange). Physical characteristics of the culture environment such as the intensity, quality and duration of light, and the temperature are also discussed.

The chapter on the technology of *in vitro* culture includes information on laboratory set-up and instruments/equipment for *in vitro* culture, the complete laboratory procedures for preparation of glassware, stock solutions, media and their sterilization. Procedures for the preparation, disinfections are also discussed.

Meristem culture is illustrated with 'Japanese artichoke' as a model system and also micropropagation, giving an example of *Saintapaulia*. Also covered is the general background of techniques and significance of anther/pollen culture and protoplast culture.

The chapter 'Biotechnologies in horticulture: Possibilities and perspectives' describes modern methods such as protoplast fusion, haploids, somaclonal variation, and molecular genetics. There is also a chapter on gene transformation and somatic embryogenesis, and on genetic aspects of *in vitro* regenerated plants.

The book contains an informative article on the mycorrhiza and *in vitro* culture, where the types of mycorrhiza, its association with specific plants, and applications of mycorrhization have been explained in detail. There is one chapter which deals with application of *in vitro* culture in disease elimination and disease resistance.

Lastly, advantages of *in vitro* culture, its economical aspects and constraints are presented. There is an account of the present and future status of *in vitro* culture of ornamental plants, woody plants and fruit trees. A list of plants for which technology has been commercialized is given.

Overall, the book covers information on general techniques of *in vitro* culture useful for beginners and students. The information could have been better organized and repetition of many aspects avoided. Although recent applications and constraints of *in vitro* culture have been covered, they should have been described in more detail so as to make the information more complete. As the title of the book indicates, an account of *in vitro* technologies for economically important horticultural crops and significance of *in vitro* culture pertaining to specific problems in these crops would have been more useful.

Tissue culture and its commercial exploitation are emerging fields and this book will be useful to people entering these fields.

Two undocumented historic earthquakes and additional information on the major earthquake of 1 September 1803 from north India

R. N. Athavale

Information about historic earthquakes noted in the records of the Peshwa period is extracted. It reveals in north Indian plains occurrence of two earthquakes not documented in the existing catalogues of Indian earthquakes. One event was felt near Delhi on 10 October 1760 and the other at Varanasi on 30 September 1803. Some additional information about the documented earthquake of 1 September 1803 has become available. It suggests that this major earthquake had its epicentre in the Garhwal area of Himalaya and it caused simultaneous damage in Allahabad, Varanasi and Gaya cities in the Gangetic plains.

The recent earthquakes of Latur on 30 September 1993, Uttarkashi on 20 October 1991 and Koyna on 11 December 1967 and the current discussion on advisability of the construction of Tehri dam in an earthquake-prone area have increased public awareness on the need of seismic studies and surveillance. Catalogues of historic and recent earthquakes have been prepared by various workers from time to time[1–10]. These inventories of earthquakes are useful in knowing about general seismicity level of an area and in preparing seismic zoning maps.

The Koyna earthquake had an initial element of surprise as it took place in an area generally considered by earth scientists as aseismic. Subsequent to the Koyna earthquake, Kelkar[11] searched the historical records of Maharashtra over the last 300 years and showed that the Western Continental margin in general and the Koyna area in particular were not as aseismic as was believed till then. He produced historical evidence for ten earthquakes over the period 1598–1832. Out of these, two earthquakes of 1757 and 1764 AD were in the Dhom–Mahabaleshwar area, where the dam on Koyna river is located.

I have recently come across another article in the 26 January 1934 issue of the Marathi daily *Kesari*[12] which contains description of two earthquake events of 10 October 1760 and 30 September 1803 which are not listed in the compilations referred to above. Further, it also provides a more graphic description about the listed major earthquake of 1 September 1803, which affected large areas of north India. The following description is about the 1 September 1803 (Bhadrapad, Shuddha Chaturdashi) earthquake:

'The earthquake took place at midday. Houses oscillated for one Ghataka (24 min). Persons sleeping on the side were turned either face upwards or downwards. The cattle on leash showed great unease. Roof tiles fell. The grain market area caught fire. Two stars fell. Their light during daytime was similar to starlight and lasted for a quarter Ghataka (6 min). People got scared. They left their houses and came out in courtyards. Everyone felt as if doomsday was today itself. This earthquake occurred at Kashi (Varanasi), Prayag (Allahabad) and Gaya, at these three places at the same time. Besides, up above near Lord Vishnu's abode Badrikedar, the city of Srinagar existed at a distance of 4–5 kos (10–15 km); in that city and in its neighbourhood, earthquakes occurred. The land parted. About 500 to 1000 houses collapsed; mountains also collapsed'.

The reference to Srinagar town of Garhwal district of Uttar Pradesh in past tense in the above account is significant. Baird-Smith[1] states that Srinagar, the capital of Garhwal state, had 700–800 houses in 1796 when Colonel Hardwicke visited it and that it was found in a ruined status by M/s Webb and Raper when they visited it in 1808. The information culled from Peshwa period records about damage to Srinagar town is thus corroborated through independent observations. Baird-Smith[1] reports on the damage caused by this earthquake in Mathura and Oldham[2] records that it was felt in Calcutta and also in the upper Ganga valley. The same earthquake was felt at Lucknow, Farrukhabad and Jabalpur[13] also (Figure 1).

Chandra[6] lists the Mathura shock and the one felt in the upper Ganga valley as separate events of 1 September 1803 and does not include the Calcutta shock for this date. Bapat *et al.*[3] list only the Mathura shock against 1 September 1803 and assign it a magnitude of 6.5. Rastogi[14] assigns a magnitude of 7 to this earthquake. Gupta[15] and Seeber and Ambruster[16] have considered four definite great earthquakes of Indian Himalaya as the 1897 Shillong, 1905 Kangra, 1934 Bihar–Nepal and 1950 Assam events and three doubtful ones as the 1803 shock discussed here, the 1833 even in western Bihar and the 1885 shock of Kashmir. The additional historic information gleaned from the Peshwa period record suggests that the earthquake of 1 September 1803, with its meizoseismal area in the Garhwal region, affecting the entire Gangetic alluvial plain from Mathura to Calcutta and felt at Jabalpur (Figure 1) in the shield area, can also be included in the category of great earthquakes (magnitude greater than 8) without any reservation.

The descriptions[12] of the other two earthquakes which do not find a place in the earthquakes catalogues referred to above are as follows.

Regarding the earthquake of 30 September 1803:

'On Ashwin Shuddh Chaturdashi (30 September 1803) two big stars fell in Kashi (Varanasi). Light shined for 4 Ghatakas (1 h 36 min). There was loud sound similar to that made by a thunderbolt. A big earthquake took place. Two-three hundred houses fell. The Bhagirathi was very turbulent for 4 Ghatakas. Rainfall occurred for one-and-a-half day. In the area (Moholla) near Bindumadhav, up to 200 houses got burnt. The water in the stream of Ganga was turbulently rising up to two spears height for a period of 3 Ghatakas (1 h 12 min). And many loud sounds occurred in the water and thousands of stars (Nakshtras) fell at night.'

The second earthquake is reported by Nana Phadnavis, a minister at Peshwa's court, who accompanied the Maratha army

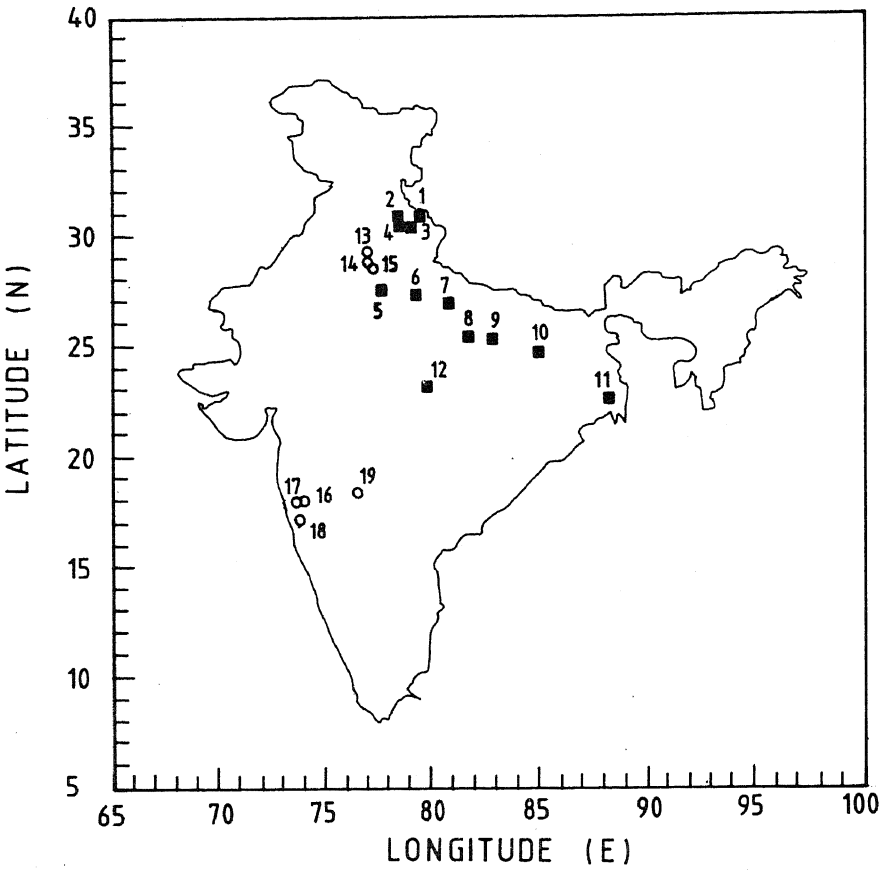

Figure 1. Map of India showing towns/sites described in the text. Square symbols are for localities affected by the earthquake of 1 September 1803. [1. Badrinath, 2. Uttarkashi, 3. Srinagar, 4. Tehri, 5. Mathura, 6. Farrukhabad, 7. Lucknow, 8. Allahabad, 9. Varanasi, 10. Gaya, 11. Calcutta, 12. Jabalpur, 13. Panipat, 14. Sonipat, 15. Delhi, 16. Dhom, 17. Mahabaleshwar, 18. Koynanagar, 19. Latur.]

on its northern campaign which culminated in the third battle of Panipat[17] fought on 14 January 1761. He records the following in his autobiography:

'There I worshiped (darshan) the Lord of the Earth (Prithivipati) as ordered by his Highness (Shriman) Bhausaheb (Peshwa). Then i came to His Highness at his army camp. Afterwards, an earthquake occurred while I was sitting with His Highness.'

The Maratha army was in Delhi–Panipat area from August 1760. According to historians, the ruler of Delhi (Badshah) was referred to in the contemporary Marathi literature as Prithvipati. Nana Phadnavis attended the anointment ceremony of Crown Prince Jawanbakht at Delhi on 10 October 1760 and then reached the Maratha army camp near Sonipat, about 45 km north of Delhi, on the same or perhaps on the next day. He, therefore, felt the earthquake at this location.

The information provided here and in Kelkar's article[11] suggests that our historical records are replete with descriptions pertaining to earthquakes and other catastrophic environmental events such as floods, droughts and meteorite falls. There is clearly a need for a forum for discussions between scientists interested in neotectonics, archaeoseismology and the past global changes (PAGES) programme of IGBP in India on the one hand and the historians and archaeologists on the other, so that the latter can look at their source material with the perspective of the former group. It also follows that any feasibility study for a major irrigation, industry or power project should incorporate a report on the environmental history of the project site, prepared by those who have worked on the history and archaeology of the area where the project is to be located.

NEW ICAR AWARDS

The Indian Council of Agricultural Research, New Delhi announces the constitution of the following New Awards to be given away from 1995 onwards.

1. **Best Institution Award**

   In order to recognize the best performance in Agricultural Research, Extension and Education, three Agricultural Awards of Rs 100,000/- each will be given to two ICAR institutes/NRC/Project Directorates and one State Agricultural University, partially out of the interest accrued from the King Boudin Award bestowed on the ICAR in 1989.

2. **Best KVK Award**

   In order to recognize the best performance of Krishi Vigyan Kendras, KVKs which have run for a minimum period of 5 years, two awards of Rs 50,000/- each will be given in alternate years. The performance will be judged in terms of vocational training, on-farm research training of the extension workers and other extension programmes, keeping in view the mandate of the KVKs.

3. **Best Extension Workers Award**

   To create incentives for best extension workers in developing extension education programmes, adopting extension methodologies and creative impact of the programme on the farming community, especially on the downtrodden, four awards of Rs 10,000/- each are to be awarded once in three years. The first award will be given in 1996 for the preceding three years i.e. 1993–1995.

   The application forms for the above awards may be obtained from

   Dr R. C. Maheshwari, Assistant Director General (CSC), ICAR, Krishi Bhavan, New Delhi, on or before 26 September 1995. The applications may be forwarded by the Head of the Institution/Directors of Institutes/State Department of Agriculture/ Horticulture/Animal Science/Fisheries and Vice-Chancellors of State Agricultural Universities. The last date for submission of applications for these awards is 1 November 1995. The last date for candidates in the Andaman and Nicobar Islands, Lakshadweep, States, Union Territories in the North Eastern Region, Ladakh Division of J&K State and Sikkim is 15 November 1995.

   Note: A copy of the proforma can be obtained from him by sending a self-addressed one-rupee stamped envelope.

Tracking transition states through bond orders

The most direct approach to the understanding of reaction mechanisms is by examining potential energy surfaces in detail. A few stationary points, viz. the minima characterizing the reactants, products and potential intermediates and saddle points connecting them in an idealized cross-section, are specially important. Within transition state theory, the information about these points is just about everything one may wish to know about the course of the reaction. Minima are directly accessible to experimental investigations. But transition states are elusive. Kinetic experiments can yield activation energies, but not any precise details of other properties of the transition state.

Chemists are not put off by the difficulties associated with precise characterization of transition state structures. They invariably visualize reactions in terms of making, breaking or rearrangement of a few bonds. The 'action' is assumed to be localized in a small fragment even in a complex substrate. The simplified notions serve their purpose; after all, many reactions are used in predictable ways to make new compounds. But can the 'arrowpushing' approach be placed on a firmer footing? Can theory help?

Bond order, in spite of being only a computable property, is a concept which has found widespread acceptance among chemists. It is intuitively reasonable besides being intimately related to measurable quantities like bond lengths and bond energies. The latter are relatively difficult to calculate using quantum chemical methods for large molecules. On the other hand, sensible bond orders can be obtained even with fairly simple computational methods. Variations in bond orders have been suggested to be useful indicators of the changes occurring during the course of a description for many simple reactions in the last few years. The inflexions noted in the bond orders have also been suggested to correlate well with the location of transition states. A detailed analysis with more complex examples is now provided (Maity *et al.*, **page 343**).

The approach employed by the authors is not going to replace conventional interpretations based on potential energy surfaces. The work is not meant in that spirit either. Just as orbital energy changes along the reaction coordinate can provide additional insights when interpreted with care, the methodology proposed based on bond orders represents another framework for understanding reactions. The language would also be familiar to nontheoreticians.

Animal welfare

Shivi, a king in the Mahabharatha, once gave protection to a dove which was being pursued by a hawk. The hawk demanded that the dove be handed over, but Shivi refused to do so, saying that he was obliged to protect it. The hawk then protested that this would mean starvation for him, and that Shivi himself would be responsible for the death of yet another living being in his attempt to save one life. In response, Shivi drew out his sword and proceeded to cut off his own flesh to offer it to the hawk and at the same time save the dove. The conflict portrayed here between the kind act of the king to save the dove and the cruelty that it would otherwise inflict on the hawk is almost eternal and haunts us in our ways of dealing with animals. The lesson conveyed, however, is simple and effective: if we do have the will, a little sacrifice on our part can achieve a lot for the welfare of animals.

King Shivis we may not be, but we could at least occasionally spare a thought for our fellow animals, exploited mercilessly ever since the dawn of our 'civilization' so that we may live a little longer, a little better. This is the theme of the special section on animal welfare in this issue of *Current Science*, a series of articles which attempt to present various aspects of our use of non-human animals.

The way we treat animals might largely rest on the contemporary philosophical strength of our civilization and on the extent of our realization that we, the humans, have a duty to think and worry about the welfare of animals just as we do about ourselves. Anindya Sinha (**page 296**) writes about these duties of the human race and reviews some of the old and new ideas that have guided our ethics of animal exploitation. This is followed by an appeal (**page 301**) by the noted primatologist Jane Goodall to initiate a dialogue on how noninvasively and painlessly animals can be used, if at all they must be, in the course of experimentation and education. She also identifies the responsibilities of the institutions of higher learning and the role they can play in minimizing the ill treatment that animals are often subjected to.

The tender relationship the farmers have with their herds of cattle, goat and sheep in Indian villages probably forms an exemplary way to incorporate the lesson from Shivi's legend. These farmers often take care of their domestic animals with extreme kindness, the kind that they show only to their own children, but at the same time they also subject them to hard work for their livelihood. It is not unusual to find, in our villages, the farmers tenderly touching their animals, hand-feeding the cattle late at night, and grooming them as they are given rest amidst the heavy working schedule. Does this physical touch elicit any healthy

response from the cattle? Natalie Waran in her article (**page 303**) on human–animal interactions explores the evidence that these do indeed greatly affect the psychological disposition of animals towards humans, their own survival, and possibly even productivity. Unfortunately, following the introduction of the western mechanized system of dairy management in India, the way cattle are treated has been changing: from a family companion to a mere productive unit. This dichotomy between the east and the west in their treatment of animals is the basis of the article by Madhusudan Katti (**page 305**), who outlines the actual realities that characterize human–animal conflict in most situations.

Natalie Waran, in yet another article (**page 308**), discusses various modifications of the immediate environment of the captive animal which should be achieved in response to its physical, social and developmental needs. The importance of both these approaches for the well-being of our otherwise exploited livestock cannot be overemphasized. Finally, N. Winskill *et al.* draw attention to a specific example of the devastation that our maltreatment of domesticated animals can wreak (**page 310**), with a paper on the behavioural abnormalities of stabled horses.

In today's difficult world, it is often quite easy to ignore whatever does not attract our direct attention. We may thus never give a thought to the hundreds of cows that produce our breakfast milk, nor remember the thousands of monkeys that have been sacrificed to produce one effective drug. At the other end of the spectrum, it may be impossible to change the ways in which the majority of our self-driven humanity thinks. There are, however, small steps that we can take so that the animals that we use can live life somewhat better, possibly a little more painlessly. As Edmund Burke said: '... nobody makes a greater mistake than he who did nothing because he could only do a little ...'.

More on the NSU

The debate on the National Science University was closed with the publication of the final reports on the NSU in the 25 June issue of *Current Science*. However, we have received more correspondence, some of which appears in this issue. Future letters on this subject will be published only if new points that have not been stressed so far are made by correspondents.

Chemical Abstracts on CD-ROM

Chemists around the world will welcome the CD-ROM version of their favourite search tool, *Chemical Abstracts (CA)*, described by its publishers as 'the key to the chemical literature', when it becomes available in 1996.

CA on CD-ROM will provide easy access to the same information available in the printed version–complete bibliographic citations, abstracts, structure diagrams, keyword indexing and comprehensive volume indexing–but with the added advantages of the electronic medium. *CA* currently covers about 600,000 documents every year, including articles from over 8000 journals. The new product will be compatible with both Windows and Macintosh systems and a user can access information from a number of access points, such as author name, keyword, substance name and chemical formula. On the price front, though, customers will have to pay an as-yet-undisclosed additional sum over the subscription price of the printed version. In return, a basic subscription will allow four simultaneous users at the same site.

Some time ago, Chemical Abstracts Service (CAS) brought out the compact disc version of the Twelfth Collective Index of *CA*, but users around the world found it less than ideal. Hope fully, the search software of *CA* on CD meets the expectation of the users.

CAS will do well to bring out *CA* of at least the past ten years on CD. Chemists tired of handling the heavy bound volumes of *CA* will be grateful. Indeed, *CA* is perhaps the last of the major science databases to be issued on CD-ROM format. The citation indexes of ISI, Philadelphia, BIOSIS, Compendex Plus and INSPEC's *Physics Abstracts* and related products are available on CD for a number of years.

Subbiah Arunachalam, Central Electrochemical Research Institute, Karaikudi.

Intensive course on 'applications of remotely sensed data on ocean colour'*

Primary production in the ocean lies at the base of the marine food chain. An accurate estimation of primary production has, therefore, several important applications: (a) it gives an indication of the amount of food available to sustain higher forms of marine life; (b) it plays a significant role in the thermodynamics of the mixed layer, which, in turn, controls the exchange of energy between the ocean and the overlying atmosphere and; (c) it provides a lower bound on the carbon dioxide flux across the air–sea interface. Fortunately, satellite imagery is providing ever more reliable estimates of primary production. This comes as a most welcome development since the spatial and temporal coverages of conventional measurements are extremely sparse.

Fifty scientists, including 22 foreign participants from 18 different countries, participated in the course.

Shubha Satyendranath, Dalhousie University, and Trevor Platt, Bedford Institute of Oceanography, both eminent researchers in this area, were instructors for the course. The topics covered included a hierarchy of models and algorithms of varying complexity to estimate primary production (notably, nonspectral, spectral, available light and absorbed light models), determination of total water column productivity, extrapolation of local algorithms to regional and basin scales and the use of ocean colour as a tool in the modelling of mixed-layer processess and biogeochemistry of the ocean. There were also five invited talks by participants on instrumentation and sensors and six on the application of ocean colour data.

The organization of the course was particularly timely, as the imminent launch of the SeaWIFS and other ocean colour satellites would soon provide considerable amount of data, which, in turn, would call for extensive modelling and analysis. The comprehensive coverage of all aspects of the analysis of ocean colour data and the sharp focus of the course was, therefore, appropriate.

P. S. Swathi, CSIR Centre for Mathematical Modelling and Computer Simulation, Bangalore.

*Sponsored by The Department of Ocean Development along with 7 international agencies (COSTED, IOC, JGOFS, ROSTAS, SAREC, SCOR, START and UNESCO) and held at the CSIR Centre for Mathematical Modelling and Computer Simulation (C-MMACS), Bangalore, during 3–7 April 1995.

International Lithosphere Project

An organizational meeting of the Indian section of the ILP task group II-4 and a seminar on 'Three-dimensional mapping of the lithosphere' was held at the Indian Institute of Technology, Kanpur, on 30 March to 1 April 1995. The meeting and the seminar were attended by scientists from a number of research and academic institutions in India. In the inaugural lecture, Vinod Gaur (CMMACS, Bangalore) discussed the structure and kinematics of the Indian continental lithosphere, including his recent work on GPS-derived strain rate in the southern Indian peninsula. A panel discussion chaired by K. N. Khattri (Dehra Dun) was also organized during this meeting to articulate significant new directions in the studies of the lithosphere.

The panel emphasized the fundamental importance of investigating the geodynamic processes at work in the Indian lithosphere. A better understanding of this basic process is essential for the design of illuminating scientific approaches to a host of important societal problems, notably, quantification of hazards posed by earthquakes, landslides and degrading environments of our resource bases such as ground water aquifers, hill and coastal terranes and biodiversity.

These problems being necessarily complex call for a systematic and synergetic application of investigative tools and approaches from a wide spectrum of earth science disciplines: geological structure and tectonics, geochemistry, geomorphology, geochronology, geothermics, and deep geophysical probes of geodesy, seismology and electromagnetics. In turn, it would be necessary to employ the most incisive statistical and information-theoretic approaches for the analysis and interpretation of a highly diverse yet related data sets.

However, whilst the desirability of investigating the key elements of the entire Indian lithosphere is quite clear, it would be prudent to concentrate the first systematic integrated efforts in defining the structure of its northern boundary – the Himalayan region – and the style and rate of geodynamic processes operating there. For, the grand scale of the tectonic processes in the Himalayas, providing a fast rate of information flow, not only offer an extraordinary opportunity for investigating their nature in a relatively shorter period but also mark this region, with dense population at its southern boundary, as one facing the highest degree of natural hazard. Creation of illuminating knowledge bases to address this problem of great social concern is, therefore, manifestly urgent.

The databases in various disciplines mentioned above are being developed by various National agencies: the IMD, GSI, NGRI, WIHG and university departments of geosciences. The creation of a modern data information system with exchange facilities would greatly facilitate integrated analysis of this data set and promote its wider simultaneous use for greater purpose by diverse groups of scientists in the country. Also, high-quality data sets generated by several international agencies, notably, digital wide-band, wide-dynamic-range seismograms and gravity and magnetic data measured from satellites, could then be progressively added to this system to foster creative approaches to the study of geodynamics of the Indian lithosphere. The panel accordingly recommended creation of a National Geoscience Information System for abstracting, structuring, quality testing and archiving the corpus of data available from national and international agencies, and facilitating its use by Indian scientists to address urgent problems of development and hazard mitigation. Such a system is conceived as being comprised of a number of component data centres in appropriate institutions equipped with quality control and archiving facilities, but integrated with a communication link. It was further recommended that collaborative programmes for developing new conceptual models be formulated, backed by incisive experiment design for generating new data sets. These proposals may then be submitted to DST, UGC, AICTE, etc., for funding. It was also recommended that some centres may be identified and supported for intensified research programmes in the new developing approaches using mathematical modelling and computer simulation.

Some approaches suggested for an effective implementation of these programmes are given below:

- Design of integrated geoscientific investigations to define the structure and tectonics of critical segments of the Indian lithosphere, with immediate focus on its northern collision boundary, using various tomographic approaches, and modelling of geomorphic, magmatic and tectonic processes.
- Development of adequate scientific expertise in the use of wide-band–wide-dynamic-range seismological data and their analysis using waveform modelling techniques.
- Development of nonlinear models of lithospheric processes and their implications to those in the crustal layer.
- Systematic deformation monitoring in critical areas of the Indian crust using GPS, and delineation of areas of anomalous strain accumulation and potential seismicity as well as quantification of strain rates.
- Nucleation of computer-aided Geoscience Information Systems at local scales in various institutions as a prelude to their subsequent integration into a National Geoscience Information System.

Ramesh P. Singh, Indian Institute of Technology, Kanpur.

Necessity of broadening science base in India

This has reference to articles published in *Current Science* about 'ills of Indian Science', 'Indian Science being drifted into obsolescence' and totally 'getting drowned in the sewage', etc. I would like to point out that such articles, in addition to having a demoralizing effect on young Indian scientists, do not reveal the reality. For instance, I feel that my branch of science (organic chemistry) is better now in India than it was 20 years before and the gap between us and the western scientists is getting smaller in this area. This may also be true in several other areas.

These facts are not insignificant when one considers the reality that the candidates admitted to S&T institutions in India come mainly from a small fraction of the 900 and odd million. So, we should compare ourselves only with countries such as Finland, New Zealand, etc.

If we wish to compete with scientists in USA, Japan, etc., then it is important to improve on the competitive level of scientists in India by making the S&T institutions accessible to candidates from the entire population. That is, instead of declining admission in S&T institutions, *de facto*, to a large section (> 95%) of our population, both the political and science policy makers should come out with plans so as to tap talent from the entire population. This would certainly improve the competitive level of Indian scientists. The Chinese have amply demonstrated this in the recent years.

For example, 20 years back, Indian students did not have problems in scoring >90 percentile in GRE examinations. Their competitors were mainly the Taiwanese and south Koreans. But these days their main competitors are mainland Chinese and our toppers from even prestigious institutions get poor 60–70 percentiles! Clearly, the Chinese students who come through a massive competition at home are able to compete better than Indians in the international arena!

More on the NSU

Apropos the rejoinder of P. N. Srivastava, which appeared in *Current Science*, 1995, **68**, 1190, may I ask the following straight questions to the author?

1. When one wants to build an institution of quality, why should one think of reservation, even for NRIs? Does it not reflect the current Indian mentality, reservation for weaker sections, now reservation for NRIs. Why should the recruitment not be on merit and merit alone?

2. If the Government is to contribute substantially for the establishment of National Science University (NSU), will it not bring pressure for reservation in admissions, and even in staff recruitment, for weaker sections of society?

3. What is the guarantee that NRIs recruited would be meritorious? People who want reservation would also manipulate and make believe that they are good.

4. What is the guarantee that NRIs would continue supporting NSU financially? People who want advantages in the beginning itself would desert the NSU once they find that they are not deriving any benefit from it.

5. Why should the NRIs not help financially the development of science in India, without any strings attached?

6. Why should the NRIs not think of improvements in IISc and in IITs by persuading the Government to change their constitution and pouring money in them to equip them well with staff and equipment? Many of the NRIs are products of these institutions and they will only be paying their debt to their Alma Mater. The NRIs, of course, would not be satisfied, for they would not have a dominant hold on the institution.

7. What is the guarantee that the NSU-trained graduates and postgraduates will have the missionary zeal to work, on relatively ill-paid salary, in colleges and universities which would continue to be ill-equipped as compared to the NSU.

8. Will not the NSU-trained graduates and postgraduates seek greener pasture in USA and other advanced countries?

9. Is the present concern of the NRIs for science in India because (to quote from Mahajan and Sudarshan (see *Current Science*, 1995, **68**, p. 1260 (1295))

(i) he does not feel a full citizen of the institution in America which controls his career,

(ii) he, having gone knocking on the American doors, believing in the universality of science, has now realized, although the realization has come rather late in the day, that American scientific establishment is less than fair to many of its most outstanding imports.

In my opinion the crying need of the hour is not setting up new institutions but strengthening selected existing institutions, such as IISc, some IITs, some universities, massively with funds, additional staff of quality and also introducing some reforms in the administration.

There are many Indians working in India who are intellectually much better equipped than most of the NRI scientists.

N. S. NARASIMHAN

Centre for Agro Chemical Research,
SPIC Science Foundation,
Mount View,
110, Mount Road, Guindy,
Madras 600 032, India.

Response:

The concerns expressed by Narasimhan are a clear case of misinformation or ignorance towards facts about which I had referred to in my rejoinder. There is, therefore, no doubt why some persons have referred to the whole project as 'naive' because they have not read my articles 'The concept of the National Science University: A rejoinder' and 'National Science University: Final Report' (*Current Science*, 1995, **68**, 1190–1198) carefully. I respond to the specific questions pointwise.

1,3. I wonder from where the author has got the idea that there will be reservations for NRIs. There will be no reservations for anybody, NRIs or Indians. The only point that has been made is that 'Further, what is wrong to expect that about 20–25 (out of a faculty strength of 200–250) well-established Indian scientists working abroad should decide to return to India for good to give a boost to this university by working here' (p. 1190). This is no reservation. 'The selection will be done with the active participation of and advice from the International Advisory Committee (p. 1194)' only on merit and no other consideration. Is this reservation?

2. As already mentioned in point number 1, there will be no reservations in admissions, staff recruitments, etc. The point is very clear to us that we would rather not have the university than have a university with reservations. The financial contribution from the government is not sacrosanct. The objectives of the university will, in no case, be sacrificed.

4. The university will be established only when the trust will be formed and there is no need to have any guarantee from the NRIs. The responsibility of raising further funds will be that of the trust.

5. No contribution or donation with strings will be accepted either from Indians or from NRIs.

6. Why should IISc or IITs not approach the NRIs for financial assistance? Who has put this restriction? Who can allege that more money has not been poured in IISc and IITs as compared to the universities? When I was in Bangalore during the last Indian Institute of Science (Bangalore) Court Meeting, a number of scientists belonging to IISc questioned the money that was poured into the Jawaharlal Nehru Centre for Advanced Scientific Research, Bangalore, and stressed that if only a part of that money would have been allocated to IISc, it would have improved the Institute immensely. Why did no one raise this issue at that time?

7,8. Why should there be any guarantee for this? Is it not a fact that many graduates of the IISc, IITs, many universities such as Delhi, JNU, BHU, Hyderabad, etc., stay on in India and has the country not benefited from them? Some of them do go out for good but others return as well. If the argument of the author is carried to the other end then only those institutions should be supported whose graduates are considered unfit for selection for going abroad. However, I have always been positive and do hope that Indian colleges and universities are going to improve in future.

9. This point refers to an article published in 1986 and reprinted in *Current Science*. The views expressed in this article have no bearing on the establishment of the National Science University. The pertinent official documents in this connection prepared by the committees appointed by the Government of India are the Concept of the National Science University and the Structure of NSU, reference to which has been made in *Current Science*, 1995, **68**, 1192.

SCIENTIFIC CORRESPONDENCE

Comments on 'What kind of a system is a human being? A cybernetic system?' [*Curr. Sci.*, 1994, 67, 936–940]

Narasimhan's account of the history of research in human cognition and his prognosis as to its future are well taken. Of concern, however, is his use of the term 'cybernetic system' without definition. Neither Wiener nor, as far as we know, Ashby, ever used this expression. The word 'system' was used by Wiener only in familiar contexts such as the solar system or the nervous system, and he never thought of himself as a 'system theorist'. Indeed, the technical uses of the term 'system' in the literature make it equivocal, and there have been complaints about 'fuzzy thinking' in this field, e.g. from Kalman *et al.*[1]. It is, therefore, essential that the term 'cybernetic system' be clearly demarcated before the question 'Is a human being a cybernetic system?' is asked. Such a demarcation will, of course, depend on how one interprets the underlying concept, *cybernetics*.

Unlike the term 'machine', which Wiener defined clearly as 'a multiple-input, multiple-output transducer', he never clearly prescribed the range of the term 'cybernetics'. Narasimhan [p. 937, col. 1 para 4] mentions Wiener's use of it to mean 'the entire field of communication and control in the animal and the machine'. Since very large tracks of engineering and almost the whole of the human and biological sciences involve communication and control, this definition is woefully general. A fuller rendition of what Wiener intended appears in his 1950 book[2]:

'Since the end of World War II, I have been working on the many ramifications of the *theory of messages*. Besides the electrical engineering theory of the transmission of messages, there is a larger field which includes not only the study of language but the study of messages as a means of controlling machinery and society, the development of computing machines and other such automata, certain reflections upon psychology and the nervous system, and a tentative new theory of scientific method. This larger theory of messages is a probabilistic theory, an intrinsic part of the movement that owes its origin to Willard Gibbs.

Until recently, there was no existing word for this complex of ideas, and in order to embrace the whole field by a single term, I felt constrained to invent one.' [50j, p. 15]

These words suggest that a better approach is to treat cybernetics not as a science *per se*, but rather as a *movement within science*, which draws attention to and focuses on the stochasticity of the cosmos, and on the new concepts that stochasticity allows, such as communication, information, teleological machines, regulation, intelligence, etc. (cf. *Curr. Sci.*, 25 December 1994, pp. 919–920). Calling Leibniz 'the patron saint of cybernetics', Wiener felt that all scientific attempts to absorb mind into nature, such as studies of machine intelligence (chess-playing automata), language, and animal and human intelligence, should come under the rubric 'cybernetical'. The central concepts are 'message' and 'machine' (or monad or black box), i.e. transformer of messages; 'feedback', while important, is not quite that central.

From this perspective, the lines Narasimhan has drawn between the three approaches to human understanding, viz. the cybernetic (in a narrow sense), the artificial-intelligence, and the connectionist, appear to be too sharp. These approaches should be seen as steps in an ongoing effort, that is cybernetical in the broad sense. This effort, the ultimate aim of which must be the understanding of the entire human being, should recognize that this being is 'the most complicated object under the sun', as von Neumann put it. Today this effort is rightly focused on understanding the 'Homo sapiens–faber' part of man. However, his conspicuously active but more difficult 'peccator' part should not be entirely overlooked.

Comments on the review of the monograph *The Scientific Methodology in the Light of Cybernetics* [*Curr. Sci.*, 1994, 67, 954–956]

Narasimhan's review contains misunderstandings as to what the term 'scientific methodology' means, and unfounded charges of omission and of exaggeration on my part.

The scientific methodology (SM) is the body of principles governing the method of inquiry used by scientists both to acquire knowledge about the world and to apply it practically. It is intended to provide the practising scientist with enough principles to pursue his craft vigorously, and to offset any doubts he may entertain as to its worthiness. The SM has, first of all, to state what it is in the world that makes science possible, and to describe its classifications and its different aspects, such as experimentation, reasoning, concept formation, mathematicization, learning from the past, and the mode of discovery. Secondly, the SM must say how the notions of message, communication, intelligence, teleology, contest, etc., which until fairly recently were left out of the scientific arena, are scientifically demarcatable. Thirdly, the SM must expose instances of faulty conceptualization. Fourthly, the SM has to say how scientific knowledge is related to the knowledge of craftsmen, philosophers and religionists. Finally, the SM must comment on how science bears on human welfare. Let us from this standpoint judge the blemishes that Narasimhan finds in his review [R] of the monograph [M] in question. They fall under 14 heads, which I have labeled I, II, ... ,XIV.

I. In [R, p. 954, para 2], Narasimhan writes that the following have not been addressed in [M]:

'(i) What is science about? (ii) What is the logical structure of science? (iii) What are the distinguishing characteristics, if any, of the activities that create science? (iv) What is the difference, if any, between scientific knowledge and commonsense knowledge? (v) Are the structures of these two kinds of knowledge similar? (vi) Do these two kinds of knowledge relate to the same world? (vii) What is the relationship between the language of commonsense and the language of science?'

Of these, (vi) is nonsensical since there is only one kind of true knowledge, that of the one world in existence. Of the rest, (i) is a little too vague to be of much significance. However, an adequate answer, to wit, *science is about understanding the world around us by the method of combining logic, mathematics and observation, which came with the Pythagoreans*, is latent in the following passage:

'The purpose of the enterprise throughout has been to understand the world around us. However, what made the work of Newton possible was the methodology of combining mathematics

and observation which came with the Pythagoreans, and the consistency with which the great successors of Pythagoras have practised it.' [M, p. 19]

The question (ii) is, of course, most germane to the SM, but it is already addressed in [M, §3]. The logical structure rests on Einstein's dictum: 'As far as the laws of mathematics refer to reality they are not certain; and as far as they are certain, they do not refer to reality', and can be summed up in the four basic principles:

PI : All the statements of empirical science, including statements of natural laws, are uncertain hypotheses.

PII : (a) The truths of logic and mathematics are devoid of factual content; (b) their certainty stems solely from the rules of language.

PIII : The truths of logic and mathematics provide the deductive vehicle which allows the transition from general hypotheses to empirically testable statements.

PIV : The concepts and hypotheses of science are objective in that each has a content exceeding that of observational terms or statements. But these concepts and hypotheses are not unique, and the choice of one set in preference to another is a human imposition. The imposition has been found to be inconsequential: the resulting theories most often turn out to be equipollent. Finally, the judgement of the significance of the observational errors is made by human convention.

Narasimhan does not say where these principles fall short, or what has to be added to complete them, that is not already in [M].

The question (vii), again germane to the SM, is addressed in [M, §4]. The answer in brief is: *the useful concepts of everyday language (e.g. blue, hot, angry) are refined and elevated into the scientific vocabulary by a process called explication* (Carnap's term). The question (iii) is somewhat vague. Obviously, eating or sleeping are not scientific activities (although practised in moderation, they are needed to 'create science'), and, obviously, observing, experimenting, making, concept forming, deducing, and abducting are. The question (iv) has the easy answer: *scientific knowledge is a refinement of commonsense knowledge*. As for question (v) the term 'structure' is not applicable to 'commonsense knowledge', until we know what the latter means exactly. Hence, as it stands, (v) like (vi) is meaningless.

To sum up, Narasimhan is wrong in saying that the two questions (ii) and (vii), which are germane to the SM, are not addressed in [M], and is himself at fault for formulating two, viz. (iii) and (iv), which are trivial and easily answered by what is in [M], and two more, (v) and (vi), whose meaningfulness is in doubt.

II. In [R, p. 954, para 3] Narasimhan states that I do not discuss in a 'systematic manner' the relationship between *pre-scientific* and *post-scientific technologies*. But what is germane to the SM is not this relationship but the one between craft (i.e. pre-scientific technology) and science, and on this enough is said in [M]. First, the role of the craftsman is emphasized in a paragraph with the heading *The Craft as Starting Point*, wherein is emphasized the input of the craft in leading to sound concept formation and thereby to the initiation of new sciences, for 'the craftsman intelligently cooperates with nature' [M, p. 35]. Such input continues to this day [M, p. 51]. Secondly, the craftsman is invaluable to science in providing good apparatus to the experimenter. Indeed, 'for a science to emerge, either Nature has to be generous in providing enough clues to the inquirer, or else a craftsman has to give him what he may need in order to experiment intelligently' [M, p. 20]. Briefly, the SM 'rests on man being both *Homo sapiens* and *Homo faber*' and '... without the craftsman, the scientist is lost' [M, pp. 50, 51]. As to the differences between the earlier (pre-scientific) technologies and science-based technologies of the last 200 years, the answer obviously is that the latter are on the whole much superior, especially in the military field. Consequently, societies that are unable to shake off the former and shift to the latter get dominated by those that do – a fact important for human history but not directly for the SM.

III. In [R, p. 954, col. 1, para 4] Narasimhan writes that the issues discussed in [M] (summed up in para 2 of this letter) have only 'a tangential bearing on ... the SM', and in [R, p. 954, col. 2, para 2] he suggests that I have tried 'to project him [Wiener] as a man for all time'. But until Narasimhan can substantiate these charges by citation of page and para from [M], neither claim nor suggestion can be taken seriously. His remaining comments in these paragraphs as to who influenced me and what I did for 40 years are irrelevant to the SM.

IV. In [R, p. 954, col. 2, para 3] Narasimhan speaks of my problematic 'attitude to cybernetics as a framework for analysing purposeful behaviour in animals and humans' but without saying what this attitude is. In [M] the noun 'cybernetics' hardly ever appears after the Preface, although the adjective 'cybernetical' does. In the Preface [M, p. 8] the 'cybernetical perspective' is described as one in which the concepts of *message, communication* and *control* are paramount. True, that on [M, p. 82], I give the Bigelow–Rosenblueth–Wiener definition of a *teleological mechanism*. But on the same page I also point out that there is an 'important difference between engineered teleological mechanisms and living systems'. Thus, this 'attitude' is some ghost of Narasimhan's own making, which needs exorcising*.

V. In the same paragraph Narasimhan goes on to say that I overstretch the 'scope of cybernetics' and 'trivialize its technical terminology' by stating that in social undertakings 'moral evil should be construed as teleological noise'. But what is incorrect about this statement? The following illustration taken from a recent lecture makes its truth crystal-clear:

'Consider a department store as an input–output transducer, the output terminals of which are sales desks operated by well-paid clerks. The clerk weighs a pound of candy for a customer, but pilfers a few pieces while packaging under the counter. Obviously, such pilfering has a dissipative effect on the successful operations of the store, and thus plays a role analogous to that played by natural noise in, say, an electronic transducer. Unlike natural noise, however, this new 'noise' of human origin, is teleological. It is created in order to fulfil a purpose, viz. to pilfer, and this desire to pilfer is a simple example of the moral evil. The filtration of this noise, unlike that of natural noise, will involve a contest between the sales clerks and the store owner and his detectives. We are led to the following:

*In the 25 December 1994 issue, Narasimhan has written an interesting paper, but it is marred by his use of the term 'cybernetic system' without saying what it means (see the previous letter).

Triviality: (a) In social undertakings the dissipation or noise caused by moral evil is teleological; (b) the filtration of natural noise is contest-free; the filtration of teleological noise requires contest.'

These issues are clearly latent in Wiener's writings on noise and evil.

VI. In the same paragraph, Narasimhan writes that I make 'exaggerated claims' in calling the study of the genetic code, molecular biology and genetic engineering 'cybernetical territory par excellence' [M, p. 83]. But again he is wrong, for these subjects are heavily involved with communication (information), control, and (other Wiener favourites such as) teleology, Maxwell's demons, self-organizing and reproducing mechanisms, as a glance at the Contents of Monod's *Chance and Necessity* (1970), Chapters I, III, IV, shows:

I Of strange objects: The natural and the artificial ... Difficulties of a space programme ... Objects endowed with a purpose ... Self-constructing machines ... Self-reproducing machines ... Strange properties: invariance and teleonomy ... The 'paradox' of invariance – Teleonomy and the principle of objectivity.

II Maxwell's demons: Proteins as molecular agents of structural and functional teleonomy ... The enzyme proteins as specific catalysts ... Covalent and noncovalent bonds ... The concept of the noncovalent stereo-specific complex ... Maxwell's demon.

IV Microscopic cybernetics: Functional coherence of cellular machinery ... Regulatory proteins and the logic of regulations ... Mechanism of allosteric interactions ... Regulation of the synthesis of enzymes ... The concept of gratuity ... 'Holism' vs. 'reductionism'.

VII. In [R, p. 954, col. 2, last para] Narasimhan questions my assertion that with regard to classification 'the scientific tradition is close to Aristotle'. But indeed it is, for Aristotle allowed 'the natural contours within the cosmos, as perceived by the mind ... to demarcate the sciences' [M, p. 95]. Obviously, since the contours perceived by a scientific mind today will be different from those perceived by even the greatest mind in 400 BC, the demarcations must change. Furthermore, a perusal of Joachim's Introduction to the *Nichomachean Ethics* will show that Aristotle saw the need for interdisciplinary work, Hence, this issue is spurious.

VIII. The statement 'science is based on faith', which heads [R, p. 954, col. 3] is a corollary of two more basic principles of the SM:

1. Science rests on the assumptions that the world is orderly and that the human mind can comprehend this order.
2. These assumptions are based on extralogical faith; cf. [M, §1]

The faith in (2) is none other than the *primal faith* on which all life depends (cf. [M, pp. 13–14, p. 16, last para]) and the religionist's faith in God '*presupposes an orderly and discoursable world and so depends on a primal faith that such is the world we live in*' [M, p. 17]. Thus, Narasimhan is wrong in saying that I claim that the primal faith is 'of the same kind as the religious faith of medieval schoolmen' [R, p. 954, last para]. The truth [M, p. 17] is that the primal faith is *more basic than* the 'religious faith' of medieval schoolmen, Vedantists and many others, including scientists; cf. [*Curr. Sci.*, 25 December 1994, pp. 917–919].

IX. Wiener has written: 'Without faith that nature is subject to law there can be no science. No amount of demonstration will prove that nature is subject to law'. But since Narasimhan does not tell us the flaw in Wiener's full argument and that of A. N. Whitehead [M, pp. 13, 14], his skepticism as to whether 'the extralogical faith of a scientist is a faith' [R, p. 954, last para] remains to be justified. Notwithstanding his skepticism of this faith, Narasimhan attaches great importance to 'the *origin* of it' [R, p. 954, col. 1, para 2]. But once the orderliness of the world is accepted by faith, its origination, while important to the child psychologist, is of zero import to the SM, for life itself, and *ipso facto* a discussion in child psychology or in any other field, would be impossible without such orderliness. In short, *one can investigate the origin of the primal faith only by practising, it.* Hence, Narasimhan's three paragraphs about Piaget are irrelevant to the SM*.

X. Regarding the notion of 'scientific revolutions' and of 'paradigm shift' (cf. [M, pp. 20–21]) Narasimhan misleads by saying 'Masani argues' [R, p. 954, col. 3, middle para] instead of saying 'Masani quotes Heisenberg, Einstein and Schrödinger to show that'. It was Heisenberg who said that the 'revolution' (*ca.* 1600) was '*a transition from the descriptive science of Aristotle to the structural science of Plato*' [M, p. 23], and Einstein who said that the relativity 'revolution' (*ca.* 1915) was '*no revolutionary act but the natural continuation of a line that can be traced through centuries*'; and on the quantum 'revolution' (*ca.* 1925) it was Schrödinger who described the wave mechanics as '*a thorough organic expansion and development, one might almost say merely a restatement of the old* [Hamilton, Jacobi] *theory in more subtle terms*' [M, p. 22]. An examination of how these great scientists do their research would show that they strive to complete and beautify the earlier mathematical equations in the light of the new experimental data, and that paradigms play no role whatever in their creative work. It is this that is relevant to the SM.

XI. Narasimhan [R, p. 955, col. 2, paras 1, 2, 4, 5] addresses the fundamental question of *abduction*, i.e. the process by which the mind is able to avoid the huge number of hypotheses that merely fit the known facts, and to hit upon concepts and propositions which yield new knowledge, i.e. *laws of nature*. All except paragraph 5 tell the true story. Paragraph 5, however, contains the incorrect statement that 'the theoretical underpinnings' (more accurately, scientific explications) of 'terms like instinct, insight, abductive skill are glossed over' in [M]. The need for such explications, far from being glossed over, has been clearly emphasized; thus:

'It remains to be discovered what factors in the human nervous system account for man's prodigious criticality in relation to learning automata, and whether Wiener's idea of grading automata in a hierarchy of types offers a fruitful approach to such study. More generally, *a scientific study of what Peirce called intunement should be on the cybernetical agenda.*' [M, p. 84]

'The far greater flexibility and criticality of biological organisms *vis-à-vis*

*In the author's earlier paper 'The illusion that man constructs reality' (*Kybernetes*, 1992, **21**(4), 11–24), the obvious contributions of Piaget to child psychology are lauded, and the dubiety of their relevance to the SM laid bare. Without the sun and the earth there would be no babies; thus, cosmic order first, babies second. Babies do not 'construct' the world; they slowly discover its order.

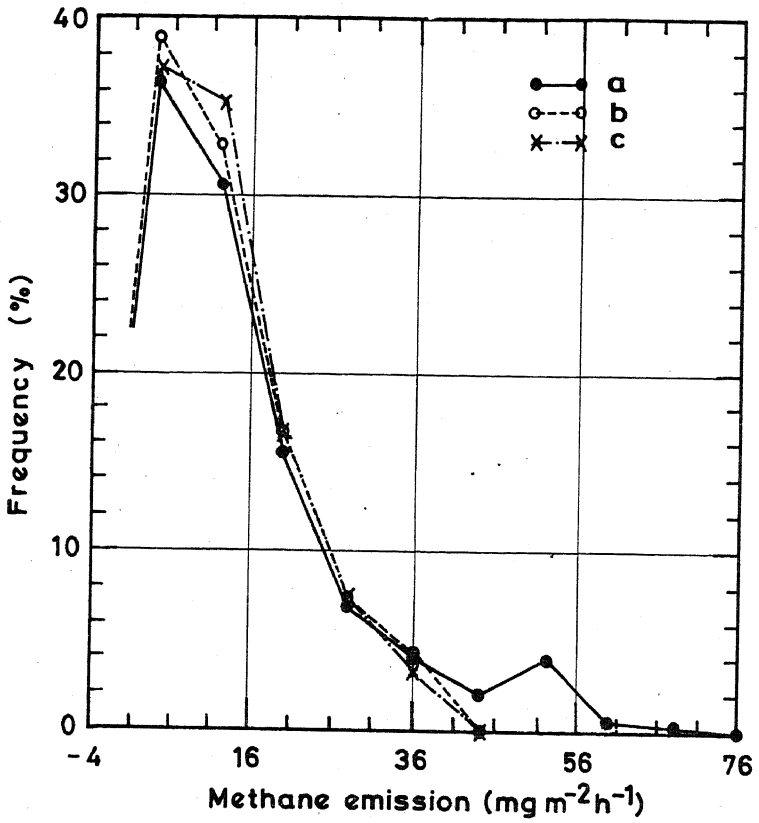

Figure 1. Frequency polygon for CH_4 emission rates. Each data point is an average of several but variable number of replicates. ***a***, all data, ***b***, exceptionally high values due to high inputs of chemical fertilizer/organic matter excluded; ***c***, values from all pot experiments excluded in addition to exceptionally high values from field experiments due to high inputs of fertilizer/organic matter.

Table 1. Calculated CH_4 emission from rice paddies on the basis of data in Figure 1

	Emission rate (mg CH_4 m^{-2} h^{-1})	Annual emission (Tg CH_4 yr^{-1})
All data		
Simple average	14.89 (±12.95)	49.13
Geometric mean	9.32	30.76
Exceptionally high values removed[1]		
Simple average	12.29 (± 8.88)	40.58
Geometric mean	8.24	27.19
Values for all pot experiments removed[2]		
Simple average	12.34 (± 8.14)	40.72
Geometric mean	8.97	29.60

Values in parentheses are standard deviations.
[1]Values from experiments with heavy doses of chemical fertilizers and paddy straw/horse manure were excluded. Most of these were pot experiments.
[2]Values from all pot experiments involving chemical fertilization and organic matter amendment were excluded.

around the world[6] and averages 105 days. Using 1.31×10^{12} m^2 rice cultivation area, a CH_4 emission period of 105 days and average emission rates, the total global emission varies from 40.58 to 49.13 Tg yr^{-1} (Table 1). Because of the pronounced skewness in the data and high standard deviations associated with simple averages, it would seem preferable to use geometric means. Based on geometric means, the total CH_4 emission varies from 27.19 to 30.76 Tg yr^{-1} (Table 1).

Inclusion of the data from artificial pot experiments or from field experiments with very high inputs of organic matter in calculations of global emission may not be realistic. A recent review indicated that the CH_4 flux response to the application of fertilizer or/and organic matter ranged from negligible to dramatic (–75 to +6857% compared to control), and varied from year to year, among periods within a growing season, and from treatment to treatment[38]. Additionally, if harvested wetland rice area of 1.236×10^{12} m^2 is used as calculated by Neue and Roger[37], the global estimate reduces to 25.68–27.84 Tg CH_4 yr^{-1}. We suggest that these values could be considered a reasonable estimate until all rice-growing regions and rice ecologies are adequately covered by flux measurements. These estimates depend much on the CH_4 emission period, which may vary substantially in different geographic regions. Assuming a 30 d emission period, as argued by Sinha[39], the estimate for global emission reduces to 7.34–7.95 Tg yr^{-1}. This estimate compares with 7.08 Tg yr^{-1} assessed by Sinha[39] on the basis of rice yield and 30 d CH_4 emission period. Thus, there is a need for substantial reduction in the global estimate of CH_4 emission from rice paddies.

Nomenclature of super heavy elements

Scientists of different countries have made different claims on synthesis of new elements. As their methods of identification were different, the criterion for discovery of elements[1] remained under dispute for a long time. Hence, the literature has reports on the same element with different names and symbols, which leads to confusion. Recent changes by IUPAC[2] in the names of elements 101–109 have evoked mixed reactions, especially in USA. This is because some old names have been reassigned different atomic numbers, in an effort to solve the dispute.

Some actinide elements were named after the place of discovery in accordance with their rare earth counterparts. For example, eka-Europium was named Americium, and eka-Terbium was named Berkelium. It is interesting to note that eka-Hafnium (104) has aptly been christened after Dubna, just as Hafnium was named after Copenhagen (Hafinia in Latin). The elements with atomic numbers 105 and above have been named after eminent scientists. (105 – Joliotium (Jl); 106 – Rutherfordium (rf); 107 – Bohrium (Bh); 108 – Hafnium (Hn); 109 – Meitnerium (Mt)). The earlier name Seaborgium suggested by the Berkley group for element 106 has not been accepted by IUPAC because it does not favour naming the elements after scientists who are alive. Some subtle changes have occurred with respect to symbols: Mv, Lw and Ha have now become Md, Lr and Hn, respectively[3–5].

Elements yet to be ratified are given temporary appellation derived from the following unique Greek/Latin roots[6]: 0 = nil; 1 = un; 2 = bi; 3 = tri; 4 = quad; 5 = pent; 6 = hex; 7 = sept; 8 = oct; 9 = enn. Instead of this system, a simpler representation with Z is also followed. For example, $(110)O_2$ is the dioxide of the element ununnilium (Unn).

Worldwide acceptance of the recent IUPAC recommendations[7] would end the confusion that prevails in the naming of these 'superheavy' elements.

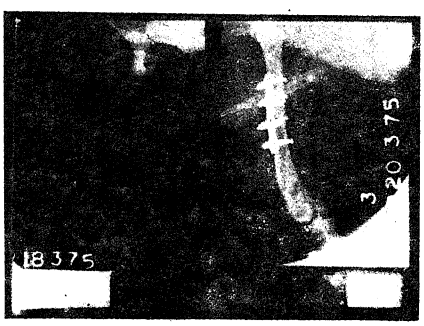
Sing, dilly dilly duckling, come and be killed,
For you must be stuffed, and my customers filled.

– Old English nursery rhyme

'. . . *violent muscular spasms, occasionally sufficient to throw the animal bodily across the cage occurred, and gradually passed into a state of general weakness ending in death.*' Some animals '*bit themselves severely, two chewing off the end of a finger, and one, the whole skin of the forearm, exposing the muscles from the elbow to the wrist.*'

– From a scientific paper investigating the effect of certain substances injected into the brain of monkeys; *The Lancet*, 19 September 1931.



In today's man-eat-man world, a consideration of the exploitation of animals, their rights, and our obligations towards them might seem trivial and fairly unnecessary. Its importance, however, lies in two kinds of arguments. The first encompasses the concept of global ecology and the unique position held by each species on this ecosphere, the Earth. The environmental movement has particularly made us aware of the often irreparable damage that we have inflicted on other species, and made many of us reflect on our duty towards the other inhabitants that share our home. Although extremely important in its own right, I will not concern myself with it in this paper.

The exploitation of animals

The second group of arguments address the questions whether our eating of other animals, our experiments on them and our destruction of their habitats are ethically defensible. This assumes particular importance if one considers the qualitative and quantitative extent to which animals are exploited to carry the burden of our modern-day civilization. The use of animal pelts and skins in articles such as shoes, belts, wallets and watchbands, and in sports goods such as footballs and boxing gloves, the use of animal excreta in fertilizers, the use of animal urine in the manufacture of perfumes and body lotions, and of animal fats in the manufacture of soap, lipstick and chewing gum are so routine and so much a part of our everyday life that few people are concerned or think about it at all. Lack of knowledge also characterizes our most intimate contact with animals, namely, our eating of them. But the fact is that farm animals, in ever-increasing numbers, are being raised in incredibly crowded, unnatural environments according to what are called 'intensive rearing methods'. Animals kept under such conditions lead lives characterized by extreme deprivation, pain and frustration. But raising livestock in this way is the only economically feasible route for the producer to meet the ever-increasing public demand for meat and dairy products. The point I am trying to make is that it is not the producers alone who are responsible for forcing animals to lead the lives they do, we, consumers, too must take a large share of the responsibility.

Even more relevant to most of us in the scientific community is the responsibility we must accept for another

Animals are often subjected to unnecessary pain during scientific experimentation. This dog had one of its limbs broken without any anaesthetic being applied in the course of a veterinary study investigating bone fracture and healing.

major cause of animal expoitation: the use of animals in scientific research. Most laboratory animals are forced to lead lives that are alien to their natures, and moreover, their confinement is characterized by deprivation and pain. This problem is again magnified as increasing numbers of animals are being confined to laboratories around the world. The following statistics should drive this point home. In the United States of America, a study conducted by Rutgers University's College of Agriculture and Environmental Sciences revealed that in the year 1971 alone, American researchers used 15–20 million frogs, 190,000 turtles, 51,000 lizards, 61,200 snakes, 1.7 million birds, 45 million rodents, 700,000 rabbits, 23,000 sheep, 46,300 swine, 200,000 cats, 500,000 dogs and about 85,300 primates[1]. The use of animals as subjects in research seems as commonplace in the scientific community as the use of animal flesh for food in the world at large.

But can such use of animals for human 'benefit' be morally justified? Concern over the treatment accorded to animals is not an abstract theoretical matter. How we treat animals affects us as humans; the quality of animal life affects the quality of human life. Thus, the need to understand and to evaluate various philosophical positions with regard to animal rights and human obligations becomes a matter of practical significance.

Human obligations

Whether man has obligations towards other animals is intimately connected with our belief and knowledge about the capacities that nonhuman animals possess. This stand becomes clear when humans believe that they have certain duties towards other human beings but not towards inanimate objects such as pebbles or clouds because they lack certain properties which human beings possess. Thus, in order to answer the question whether we have duties towards other animals, we have to first answer another question: What capacities must a being have if we are to feel any responsibility towards it?

There are three things some or all of which have been recognized by various thinkers to characterize beings towards whom we, humans, have some duties[2]. These are: (1) rationality, or the capacity to reason; (2) autonomy, or the capacity to make free choices; and (3) sentience, or the capacity to feel pleasure and pain.

The idea that a being must be rational in order that we may have some duties to it actually goes back to Aristotle, though it was very strongly advocated in the thirteenth century by the Catholic philosopher–theologian St. Thomas Aquinas[3]. Aquinas regarded rationality or intellect as a capacity that makes beings more or less perfect. Man, who has some degree of rationality, was thus considered more perfect than other animals, who lacked this capacity. He also believed that so far as our world was concerned, the less perfect beings could be subordinated by the more perfect ones; man thus need have no qualms about eating the lower animals for it is not contrary to nature, as God designed it to be. With regard to animal sentience, Aquinas believed that it was possible to treat animals cruelly since they do have the capacity to feel pain, that is, to cause them unnecessary pain. Although he did think that it was wrong to treat them in this way, he did not believe, for the reason mentioned earlier, that man had any obligation towards them to abstain from treating them cruelly. However, we do have duties towards lower animals insofar as our treatment of them leads us to sin against some rational being, either human beings or God. In fact, Aquinas did believe that people who treat animals cruelly are naturally inclined to treat rational beings in a similar way. We thus do have indirect duties towards other animals, only those borne out of charity.

Aquinas' views can and have been challenged by a number of later thinkers on three principal grounds:

1. Is there any evidence that cruelty to animals leads to cruelty to human beings? For if there is no such evidence, then, according to Aquinas' belief, it would not be wrong to treat animals cruelly; this, in itself, can be considered a debatable point.
2. We could agree with Aquinas that a being must be rational in order for us to have duties towards it, and then point out, as had been done much earlier by the Greek moralist Plutarch[4], that some of the lower animals may have the capacity to reason, although not to the extent that man has. This is a point that has now come to the fore with much of our research in human cognition being focused on comparative studies on the nonhuman primates and other highly social mammalian species.
3. A more fundamental objection disputes the very basis of Aquinas' proposition and questions whether the property of sentience should not be considered a more concrete ground to determine our moral obligations rather than that of rationality. According to this view, again put forward very strongly by Plutarch, and later supported by the English philosopher Bentham[5], it is enough that a being can experience pain and pleasure for us to have a duty towards it of not causing any unnecessary pain. And this is a direct duty, an obligation quite independent of whether our treatment of animals reflects our treatment of other human beings.

Does this mean that it is wrong to kill an animal as a source of food or to inflict pain upon it in the course of a scientific experiment? The answer, according to most thinkers, would appear to be no. Plutarch, for example, concedes that it would not be wrong to kill and eat an animal if doing so is necessary to save a human life. However, he does maintain, and this should strike a familiar chord in a number of us that it is not necessary to eat the flesh of animals to survive or attain sound health. Moreover, he believes that raising and slaughter-

ing of animals are dictated not so much by consideration of health as by that of taste. And since these are obviously unnecessary pleasures for men to indulge in, he goes on to argue that the pain caused to animals by such a treatment is also unnecessary. Thus, although there may be special circumstances in which the consumption of animals is not wrong, Plutarch believes that it is usually so.

Bentham, adopting yet another viewpoint, argues that our treatment of animals would be wrong if the animals suffered more pain than the amount of pleasure human beings received. He, in fact, incorporated the essential basis of moral equality in his utilitarian system of ethics as 'each to count for one and none for more than one'. Although later thinkers have also agreed that everyone's interests should be given such equal consideration, they have not been able to agree on how conflicting interests can be best equated[2]. Another important position in this regard is that held by the renowned missionary and philosopher Albert Schweitzer, who makes it clear that he is, in principle, not opposed to using animals in scientific research, though he speaks very forcefully against their use in 'unnecessary' research[6].

A final viewpoint which cannot be neglected in this discussion is that of Singer[7]. Even at the risk of being labelled an extreme radical, Singer defines most of the above-described ideas as products of our 'speciesist' way of thinking. A speciesist, according to him, is a person who 'allows the interests of his species to override the greater interests of members of other species'. Speciesism thus shares a number of features with sexism and racism, the most important one being a systematic refusal to apply the principles of justice in an equitable fashion. Singer raises the problem of scientific experimentation on animals and argues that the question of whether one would be prepared to let thousands of people die if they could be saved by experimenting on a single animal is akin to asking whether the same experiment could be performed on a human infant. Singer concludes that if the experimenter is not ready to do so, then his readiness to use nonhuman animals is simple discrimination, since adult mice, dogs and monkeys appear to be more aware, more self-directing, and, as far as we can tell, as sensitive to pain as any human infant. According to Singer, there appears to be no relevant characteristics that human infants have but adult mammals do not have to the same or to a higher degree. Moreover, in case of a counterargument that the human infant, if left alone, would develop into more than a nonhuman, he argues that this would still give us no reason for selecting a nonhuman animal rather than a human being with severe and irreversible brain damage as the subject for our experiments. It is thus Singer's belief that the routine use of animals as food and their use in scientific experiments is an expression of unreasonable prejudice and, like racial bigotry, should be fought against with all our compassion and respect for life.

Animal rights

The question of whether animals have rights is intimately related to our understanding of human and animal nature and also to the question of whether we have obligations towards other animals. A major school of thought is of the notion that whenever one being has an obligation towards another, the other being has a corresponding right against the first and *vice versa*[2]. This is known as the correlativity thesis. If we do have some duties towards other animals, it, therefore, necessarily follows that animals have corresponding rights that we must respect.

An interesting criticism of this viewpoint argues differently. It might generally be favourably considered, for example, that we do have certain duties towards preserving our natural ecosystems, or even the great works of human creativity such as the frescoes of the Ajanta caves. Very few would, however, agree that our oceans and forests, as also the Ajanta paintings, have rights. The correlativity thesis may not thus be too widely applicable.

Counteracting the above criticism, proponents of the thesis postulate that it is only the cases of direct duty that should be considered, while the criticism clearly involves examples of duties that are indirect. Thus, if we do have a duty towards our great works of art, it is not something that we owe to them. It is something that we owe to our future generations, for the loss of the Ajanta frescoes would lead to a loss in their enjoyment of beauty. Similarly, our indirect duty towards our woodlands and oceans only symbolizes our direct duty towards our descendants; the correlativity thesis is, therefore, upheld. Feinberg[8] is a notable proponent of this thesis, and has strongly advocated the rights of animals in accordance with our direct obligations to them.

But what is a right? Feinberg believes that to have a right is to have a claim to something or against others. Therefore, if an animal has a right to life, this would imply that it has a claim against others not to take its life. McCloskey[9], on the other hand, defines a right as an entitlement. Thus, if an animal has the right to eat whatsoever it pleases, it is entitled to such food. The difference between the two is that to have an entitlement does not necessarily require one to have any claims against others, while to have a right can be a basis for making such claims. Which of these two analyses is correct? Which one would be more appropriate for nonhuman animals? These are controversial points and unfortunately, such discussions have tended to obscure the main question of whether animals have rights at all, leading the noted English humanitarian Salt[10] to comment, in an article as early as 1912, that 'the controversy over "rights" (is) little else than an academic battle over words'. The situation remains much the same, even today.

Another problem that is often raised is that even if animals do have rights, they lack a language to articulate their claims or entitlements. This, of course, should not pose a major problem since it can always be argued that amongst human beings, very young children, the aged and those mentally deficient are also incapable of articulating their rights; yet we never do dispute their rights.

Yet another question that is important in this regard is what kinds of rights are there at all. At least two kinds of rights can be distinguished – (1) Special rights: these can be acquired because of what we or someone else has done, and not because of what we are. An example is that of a beneficiary to an inheritance. (2) Natural rights: these are what a being has by virtue of being what it is. The rights to life, liberty and happiness are included under this category because they cannot be acquired because of what one does. These are, therefore, inherent rights.

Salt[10] has suggested that animals do have special rights since they are entitled to certain legal rights; a different view is that of the British political philosopher Ritchie[11] who has argued that works of art are also protected by laws, but cannot be conceived to have legal rights of any kind. A more controversial issue, however, is that of whether animals have natural rights. This is not surprising since natural rights are those which a being has by virtue of its nature, and the nature of nonhuman animals is itself very controversial. Hence, the question which has to be raised now concerns the nature of beings that can have rights and whether animals can be considered to be such beings.

Possibly the most prevalent view in this debate is that a being must be rational if it is to be capable of having rights. However, as discussed earlier, a number of thinkers, Aristotle and Aquinas being prominent among them, are of the opinion that animals are apparently incapable of reasoning and, hence, have no rights against us. A major opponent of this argument is Feinberg[8] who has again pointed out that children and the mentally ill may not demonstrate any ability to reason but that does not deprive them of their rights. He has used an argument similar to Singer's in pointing out that even if children are considered to be potentially capable of reasoning, the mentally feeble are definitely not. Hence, if rationality is considered to be a criterion for having rights, Feinberg suggests that at least some human beings should be excluded from this group and wonders whether or not this would be too heavy a price to pay.

Another view is that a being must have interests if it is to have any rights; in other words, it must care, or be concerned about what happens to it. Not surprisingly, this has again led to a widespread debate. Some thinkers like Feinberg[8] have argued that animals have a 'conative life' with wishes, hopes, urges and impulses, thus raising the possibility of 'the good' of an individual animal. Other authors such as McCloskey[9] have consistently opposed such a view since they are of the opinion that animals have no demonstrable interests.

Yet another property of a being with rights has been believed to be sentience, that is, the capacity to feel pain and pleasure, a point that has again been discussed above. Ritchie[11] makes a very strong argument against attributing rights to animals on this ground. He notes that animals can never be accorded equal rights with human beings since this would imply, rather absurdly, that no animal could be put to death without a fair trial, and that it would be our duty to protect weak animals from the attacks of the strong. If, on the other hand, they are considered to have rights inferior to those of man, this would merely be an excuse for human interests to override the interests of animals in determining how animals themselves should be treated.

It should, of course, be made clear that even if we assume that animals are beings that can potentially have rights, we still have no answer to the question of whether they actually do have rights. Another dimension to this debate is added by thinkers who believe that animals do have rights but seem to disagree on what exactly are the rights that animals possess. Regan[12], for example, believes that they have a natural right to life if it is supposed that all human beings do, while Feinberg[8] feels that they have a right not to be treated cruelly. Salt[10] believes that animals have a right to exercise their cognitive and emotional capacities, and Rachels[13] argues that at least some animals have the right to property and to liberty. This point is a particularly interesting one since Rachels clearly refers to moral freedom exactly in the same way that has been proposed for human beings as well, and recent experiments with chimpanzees have shown that they have limited abilities to express empathy and compassion, human traits traditionally regarded to be morally admirable[14].

Where do we stand?

The problem of animal rights has obviously raised more heat than shed light on what our obligations should be towards all nonhuman animals, particularly in the way we treat them for our benefit. Some of the contentious issues relate to what is a right, especially for an animal, and what kinds of natural rights can animals lay claim to while being entitled to other special rights. Other questions, such as whether animals do have interests, or how self-aware or conscious they are, are more factual and may even be answerable one day given our new interest in animal cognition and our enquiry into the workings of the animal mind.

The whole issue, however, in my mind, still remains as ambiguous and controversial as it was in the day of Aristotle. And the foremost reason for this seems to be the inevitable subjectivity with which each of us perceives animals and our relations with them. We still

On Shri Morarji Desai and the rhesus macaque

'The moral status of a country is known by the way it treats its animals.'

– Mahatma Gandhi

The rhesus macaque (*Macaca mulatta*) of north India has, since ancient times, played an important role in the ecology, culture and traditions of India. The close interaction of these macaques with the people of our country forms perhaps the most intense relationship between human and nonhuman primates anywhere in the world.

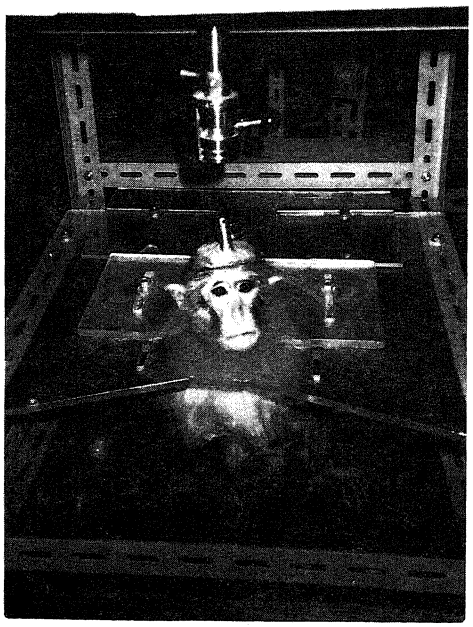
Easily maintained under laboratory conditions, however, the rhesus monkey has been extensively exploited in biomedical research because its disease spectrum is apparently very similar to that of human beings. In the early sixties, India was exporting about 200,000 to 300,000 monkeys *every year* to Europe and USA, and this had obviously considerable impact on the wild populations of this species.

In 1977, the International Primate Protection League (IPPL) gathered documents about the apparent misuse of imported Indian rhesus monkeys in military experimentation in the United States. India had lifted an initial ban on rhesus exports in the late fifties. This ban had resulted from the heavy mortality occurring amongst the transported monkeys. There were, however, conditions placed on the use of monkeys when exports resumed. Each individual shipment had to be accompanied by a 'certificate of need' which guaranteed '. . . (1) that the monkeys now being purchased will be used only for medical research or the production of antipoliomyelitis vaccine . . . ' and (2) that . . . 'they will receive humane treatment under our care'.

The IPPL felt that the radiation experiments being performed on hundreds of rhesus monkeys by the US military at various installations flagrantly violated the US–India agreement: in some experiments, monkeys were trained by electric shock to run in large circular treadwheels, they were then exposed to massive lethal doses of radiation and placed back in the treadwheel, and their agonized efforts to run were observed by scientists. In one experiment involving 131 monkeys exposed to between 2500 and 80,000 rads, the following responses to radiation were seen:

'Extreme forward slumping in crouching posture; whole body convulsions; spasticity; rolling eyeballs; stumbling and falling; blind, apathetic facial expression; muscular tremors; vomiting and retching; frequent shifts in body position and posture; wild purposeless twisting, twirling and throwing of the body; uncoordinated leaps on hearing a sound; crawling and frantic pushing and scraping of sides, back and belly on floor of cage; and passive draping of the head over the back while in an awkward, crouched, clinging posture.'

The IPPL initially tried to get the US authorities to stop these experiments. On failing to do so, they contacted the then Indian Prime Minister, the late Shri Morarji Desai, their Indian advisers and the Indian Press in order to mobilize popular and government opinion.



On 3 December 1977, India's export ban on monkeys was officially announced. It is to the credit of Shri Desai that in the face of increasingly mounting pressure from powerful lobbies, he stood firm. This policy was later continued by his successors including the late Smt Indira Gandhi, again inspite of considerable political pressure.

In an attempt at historical revisionism, claims were made by US scientists (in a magazine article) that the Indian ban had resulted from conservation concerns and the dwindling number of the rhesus. This claim was subsequently retracted when Shri Desai, who had by then retired, countered this in a handwritten letter to the IPPL:

'You are quite correct in saying that I banned the export of monkeys on a humanitarian basis and not because the number was lessening. I believe in preventing cruelty to all living beings in any form. This is the ancient Indian culture . . .'

Later, a survey by the Zoological Survey of India determined that there were only 200,000 rhesus monkeys left in India. The trade had taken a heavy toll. The teeming millions of former days had indeed disappeared.

A life-long vegetarian and animal lover, Shri Morarji Desai rejected medical treatment and vaccinations throughout his life. The monkeys left may not know it, but they owe their lives and freedom to him. They are, in their way, his living monument.

have not been able to come to terms with our biases and prejudices in the matter of human race relations, religion and sexuality. What hope remains for our attitude towards animals?

Schweitzer[6] fully grasped the enormity of this problem and realized that we are indeed far from a final solution. He thus concludes his brilliant essay entitled 'The ethic of reverence for life' with the following words, and I can think of no better way than to end this essay with them:

'Wherever any animal is forced into the service of man, the sufferings that it has to bear on that account are the concern of every one of us. No one ought to permit, insofar as he can prevent it, pain or suffering for which he will not take the responsibility . . . The ethic of reverence for life . . . inspires us to join in a search for opportunities to afford help of some kind or other to the animals, to make up for the great amount of misery which they endure at out hands, and thus to escape for the moment from the inconceivable horrors of existence.'[6]

In late 1994, Jane Goodall, the eminent primatologist and now a noted advocate for the noninvasive use of animals in research, gave a call to academicians the world over to participate in a dialogue. This was essentially aimed not only at raising the awareness of researchers, but more importantly, at opening up a serious discussion on the ethics of using laboratory animals in often painful and sometimes relatively unwarranted basic and medical research. We reprint below some excerpts from this call.

On the use of animals in research and education

Jane Goodall

Green World Center, PO Box 45, Highgate Springs, Vermont 05460, USA

The use of nonhuman animals for the purposes of humans has long been taken for granted in our culture, and has been institutionalized by entire industries. In recent years, however, a new awareness of animals has been developing, and new attitudes and practices have come into being.

Over the last two decades, the ethical and broad scientific implications of the use of animals in laboratory experiments have come to be examined more and more critically, and new research methods have been developed. There may now be some consensus among scientists, as well as among the public, that the use of animals raises ethical questions that must be dealt with.

However, discussion of the use of animals in general and as experimental subjects in particular has been polarized and contentious. Research scientists and animal rights advocates have regarded each other with distrust, and constructive dialogue has been scarce. Stereotypes of the researcher as unfeeling, and of the animal advocate as fanatical, have been persistent.

It is time for the ethical, scientific and practical issues raised by the use of animals in research and education to be aired anew, with a fresh measure of good will.

By and large, institutions of higher learning have not paid enough attention to the status and treatment of animals in society and in the institutions themselves. We,

Animals are frequently subjected to avoidable torture. This animal is fistulated – a process of cutting a circular hole of about 25 cm and covering with a removable plug so as to draw the contents from inside whenever needed.

therefore, urge that educational programmes and public forums, such as conferences, symposia, debates, film showings and seminars, be organized to consider the full range of questions raised by animal experimentation and by the use of animals in academic settings.

For example:

♦ What are the ethics of using animals as tools for human purposes, and of invasive or otherwise harmful experimentation on animals? Do animals have a right to be treated as ends in themselves and not as means only?

♦ What are the practical limits on the pain and suffering to which nonhuman animals in laboratories can be subjected? What kind of protection is given by existing laws and institutions? How common are practices that involve unalleviated pain? Are such experiments ever justified? Is there a conflict between limits on pain and suffering and the advancement of science or academic freedom?

♦ What animals are subjected to what experiments at your school? What are the experiments most harmful to animals? Do any involve causing pain without administering pain killers?

♦ To what degree have animal experiments been useful and valuable? What role have they played in the history of medicine? With respect to the future: would human health suffer if medical research were guided by a new vision in which animal experiments had no place? Would it benefit?

♦ There is an array of research methods, including clinical study, epidemiology, *in vitro* tissue culture research and computer modelling, that do not use animals. What is the adequacy and scope of these methods?

♦ Animal experiments generally begin not with sick animals in need of healing, but with healthy animals, who may then be innoculated with approximations of human diseases, or exposed to toxic substances, or subjected to a variety of surgical or other procedures. Psychological experiments have included work on such themes as 'maternal deprivation' of primates and 'learned helplessness', and military experimenters subject animals to wounds and burns. What would be the effect on medical science if experiments were limited to attempts to heal already sick or injured animals?

♦ Is the elimination of animal experiments a worthwhile goal? What about reduction in numbers of animals used, replacement of animals with nonanimal methods, and 'refinement' of experimental procedures? If such goals are worthwhile, how should they best be achieved? What is being done towards these ends today, and what is not being done that could be? How much room for improvement is there?

♦ Under what conditions are the animals at your school housed and cared for? Are their cages kept clean? Are their physical needs cared for adequately? Do they have veterinary care? Are their psychological and social needs met? How does the disruption of normal family life affect them? Do they receive loving attention? Can they be visited by members of the community? If not, why not?

♦ Millions of animals each year are killed for dissection to teach students life sciences. Is dissection necessary as an educational tool? What options are in use at your school for students who conscientiously object to dissection?

♦ Who are the suppliers of animals for dissection at your school? How many animals are killed each year for dissection? How much is paid for them? What are the conditions under which these animals are bred or captured and under which they are maintained and killed? Are visits to the suppliers' premises possible?

***

For help organizing a forum, The Green World Center will provide consultation, advice, and resources concerning

(a) organizing forums, film showings, educational activities and events;

(b) educating yourself and others about the issues related to animal experimentation;

(c) learning about animal experimentation on your campus.

Resources include speakers, literature, and an excellent Canadian Broadcasting Company video on animal research with David Suzuki.

If you think you might like to help in any capacity, or if you just want to learn more about animal experimentation, please write to or phone:

Human–animal interactions

N. K. Waran

Institute of Ecology and Resource Management, School of Agriculture, University of Edinburgh, West Mains Road, Edinburgh EH9 3J/G, Scotland, UK

There has been limited research conducted on the importance of the human–animal relationship. This paper describes the ways in which human behaviour or attitude might influence the welfare of tamed animals.

That man is important in an animal's environment is not disputed. Direct interactions between humans and animals have always been a part of the animal production system. The way in which the animals respond to human contact is governed by the way in which they perceive humans, and this is influenced both by their early developmental experience and by their natural responses or genetics. In general, it is believed that domestic animals are less fearful of humans, their flight distances are shorter than their wild counterparts, and they are more able to cope with human intervention. But animal responses are at least in part governed by fear. The fear response of animals is thought to be one cause of a chronic stress situation. Simply by being in, and imposing themselves on, the environment of an animal, humans induce fear and adverse reactions in the animals[1].

Animal responses to humans have been measured. For example, in battery-housed hens there was an increase in the resting heart rate from 140–240 beats/min up to 280–350 beats/min when a human entered the building; and rose to 480 beats/min when the human approached the cage and encroached upon the birds' natural flight zone (or personal space).

Effect of handling animals

Recent studies have shown that different handling procedures influence the performance and behaviour of animals. Growth rates in pigs were shown to be adversely influenced by what were termed 'aversive' and 'negative' handling. Pigs were conditioned to elicit a particular response from a human every time they interacted. The aversive treatment involved prodding with an electric prod every time a pig approached a human, and negative treatments involved a human approaching the pig in an upright posture and reaching towards it. Growth rates were approximately 10% lower in these treatments than in minimal contact or positive contact treatments. The reduction in growth rate was attributed to the chronic psychological stress experienced by the animal as a consequence of the handling treatments. In order to test this, the morphology of each treatment groups' adrenal glands was examined; it was found that the area of the adrenal cortex in pigs that experienced aversive treatments was almost 30% greater than those subjected to minimum, or positive treatments[2].

In other studies[3], reproductive performance has been shown to be influenced by handling treatments. When gilts were conditioned to expect to be scratched and stroked by humans, or pleasantly treated, they were easily mated at second oestrus, with a pregnancy rate of 87.5% as compared to only 33% in gilts that had been conditioned to expect a shock from an electric prodder. Boars in the unpleasant treatment groups were on an average 31 days older before they demonstrated a fully coordinated mating response, and their testicles were 10 cm^2 smaller. Measures of the concentration of plasma cortiosteroids in the absence of humans showed higher concentrations in all pigs following the unpleasant treatment.

Thus, it appears that different forms of handling can influence growth and productivity, and that it is probable that this is due to the animals' fear response to humans. There are several more examples of the effect humans have on farm animals: milk yield has been shown to vary between stockpeople; handling can negatively affect ovulation rate in ewes; regular handling during early development can enhance growth in broilers (neat-producing hens), and so on. It is obvious that

we need to understand more about these effects and, in particular, we need to know how to have a positive effect on the animals under our care.

Is there an optimum level of handling?

It has been suggested that one way to influence an animal's perception of humans is to handle in a positive way early in development. This first indication of the positive effects of handling in early development was shown in Denenberg's work on the 'gentling' of rats in 1964 (ref. 4). Young rats were stroked for a short time every day, what Denenberg termed 'introducing extrinsic stimulation'. He found that rats performed better in learning experiments and were less fearful in tests later. Although in most cases this early handling has been shown to reduce the fear of humans in rabbits, chickens, pigs and cows[5], it is often a very small effect and tends to be specific to certain handling procedures. In some cases, the effect of handling early on has had no effect, or even a negative effect, making animals even more fearful. For example, when calves were artificially groomed in the first 24 h of life, they stood up faster than ungroomed controls but they absorbed immunoglobulins at a lower rate[6]. There is very little understanding of the mechanisms underlying these apparent positive effects. Handling pigs at an early age can reduce excitability, making them easier to drive[6], but too much handling may result in an animal with such a reduced flight zone that it no longer moves away from a human, thus making it impossible to handle. A good example of this is orphan lambs reared by humans – apart from the health problems they may experience, these animals are often difficult to manœuvre as part of a flock.

It would thus appear that there is an optimum level of handling during early development that leads to a reduction in fear responses toward humans, but leaves the human the dominant figure in the animal's environment.

Are there sensitive periods of response to handling?

It has been suggested that humans can take advantage of the sensitive periods during an animal's development to condition it to certain cues. This is most obvious in birds that are reported to have sensitive or critical periods after hatching, when the bird is particularly sensitive to extrinsic stimulation. The term 'imprinting' describes the attachment that birds develop to their parents or peers during this time. In a study of game birds, where it is important that birds are fearful of humans, it was found that exposure to humans during the first 2 days after hatching resulted in birds being less fearful of humans, allowing them to approach much closer before showing the escape behaviour than birds exposed to humans only after the first 2 days. It has been suggested that other animals are also particularly sensitive at certain times in development. Hemsworth and his colleagues suggest that a sensitive period existed in pigs prior to 8 weeks of age, when they could be socialized to humans[5]. Sensitive periods may occur also later on in life, such as during parturition, when bonding between dam and offspring takes place. Cows handled during their first calving have been shown to be easier to handle and display less flinch, step and kick responses during their first 2 weeks of milking, indicating that they were less fearful of the handling procedure. It has also been suggested that by encouraging the cows to develop a general attachment to humans during the sensitive period at parturition, the cows become less fearful later[6].

Training the animals

Animals can also be trained or conditioned to accept certain restraining devices if they are positively rewarded in some way. Teaching animals to behave in an appropriate way depends on the animals' ability to make certain associations, though animals are thought to be generally limited in their ability to learn. Constraints on learning have been seen in laboratory experiments with pigs which, in response to a food reward, tend to perform their species-typical food-searching activity – rooting[8]. In addition, training depends on an animal being able to remember the association. Training is often time-consuming and sometimes impractical where animals remain in a system for only a short time; but it has been used with sheep and cows with promising results. Sheep trained to run a race and to enter a handling machine for barley food rewards, have been shown[9] to run the race quickly from year to year. Dairy cows have been conditioned to move from their field to the milking parlour in response to the sound of a bell, and an estimated 1 h of a stockman's day can be saved in this way[10]. Natural leader sheep or Judas sheep can be trained to lead a flock through a slaughterhouse[11].

It appears, therefore, that humans can have considerable positive effects upon farm animals but can also have negative effects. Human behaviour is often inconsistent and dependent upon mood, and humans are often perceived as a fear-provoking stimulus. It has been suggested that automation of animal units might be more predictable and, therefore, more easy to 'adapt' to. Mechanized broiler and turkey catchers are currently being developed and have been shown to provoke lower stress responses than normal procedures by humans. Food for thought!

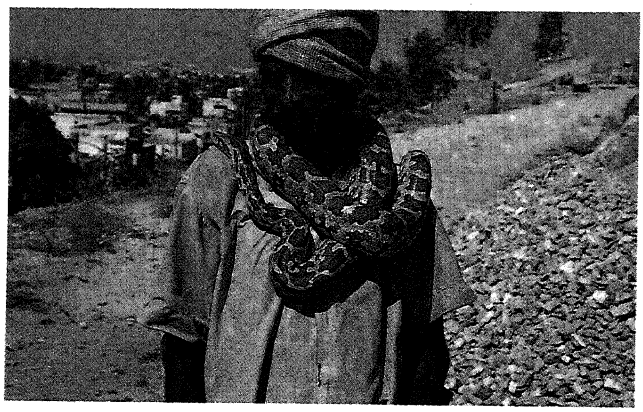
Conflicts or coexistence?

Madhusudan Katti
Department of Biology, University of California, San Diego, USA

The sprawling American city of Los Angeles has obliterated vast areas of natural habitat in southern California, and its suburbs continue to encroach upon the remaining fragments of forest and coastal sage scrub, for condominiums and recreation. The Angelenos forest has, amazingly enough, survived to this day, and is one of the remnant fragments of wilderness near the city. Even this is surrounded by suburbia – and is a source of frequent conflicts between humans and wildlife.



A young mother jogging alone one evening on a mountain trail in the suburbs got killed by a mountain lion: the first known mountain lion attack on humans this century! The local police and fish and wildlife officials immediately swung into action and, in a couple of days, tracked down and killed a female mountain lion. Shortly after they confirmed – using genetic tests of hair samples – that it was indeed the same killer animal, a solitary mountain lion cub was found near where the jogger was attacked. The cub was then sent to a zoo. It seems likely that the jogger strayed too close to the cub – *Had she seen the animals? Did she deliberately approach them too close (like so many Americans brought up on the ideas of cuddly wild animals often do)? Or did she just blunder into them*? – and provoked the mother into attacking her.

About a month after the mountain lion attack, a big black bear strayed out of the Angelenos forest and wandered into a suburban mall. Panic ensued and the local police and wildlife warden were alerted. The game warden soon shot the bear dead after unsuccessful attempts to tranquilize it for translocation. A few weeks later, a panic-stricken 911 (the emergency telephone line) call from another LA suburb reported another black bear which the caller could see outside her/his window near a school. When the cops and game warden rushed in, they found the bear perched up in a tree *looking at some children playing in the schoolyard* – so it had to be shot dead too!

Reading about these incidents in the long, hot Californian summer of 1994, when a vast forested area outside LA was burnt down (by arsonists?) and huge tracts continued to burn all over the northwestern US, I could not help but wonder if we in the third world had anything to learn at all from this, the world's most advanced, industrialized, first-world nation, in terms of managing our wildlife and natural habitats.

I myself grew up in Bombay, a city often compared to Los Angeles or New York, but much worse in terms of infrastructure or civic amenities, and on an average, offering a lower quality of life to its inhabitants. Unlike LA, Bombay also faces a shortage of land to accommodate its burgeoning human population. Yet, bordering the megalopolis' northern suburb of Borivli lies a 100 km^2 tract of tropical forest protected in the form of a National Park. The forest is in remarkably good shape, considering it is completely surrounded by over 15 million human beings. The park also has a resident population of leopards estimated at around 20–40: certainly too high a density of large carnivores to be supported by the habitat. The Indian leopard is a larger animal than the North American mountain lion, with a long and continuing history of man-eating problems that keep cropping up all over the country each year. Many of the Borivli leopards, lacking space and food inside the park, venture outside the forest at dusk to pick up dogs and other small animals from the shanty towns bordering the park. Sometimes the prey include human children, and even adult humans have been attacked and killed. Yet, the leopards are tolerated and their population allowed to build up over the past many years. It was only recently – responding to a public outcry after a child's killing – that the forest department trapped two individuals, which, unfortunately enough, bashed themselves against the cages and died.

The Borivli leopards are by no means an exception to man–animal relations in India. There is another long-standing, recurring conflict between a large mammal and human beings in eastern India for which the solution still eludes the Forest Department. This is the case of the famous Dalma or Bihar – Bengal herd of elephants:

Animals are often entwined into the lives of rural Indians. Although frequently employed in earning a livelihood, they are also treated as members of the extended family.

a remnant population of about 40 animals that has lost almost its entire home range of tropical deciduous forests to the axe and the plough. This herd – of a species renowned for its long memory – flow wanders across the hills and plains as if in search of its lost homeland. Inevitably, they come into conflict with peasant humanity, which happens to produce the only foods now available to the elephants. So the elephants undertake their annual migrations after the monsoons carving a trail of destruction among the farms and villages: large areas of crops are laid waste – from the human point of view – and frequently, humans who dare to defy the giants get killed. Last year, its incredible march led this herd almost into Calcutta city: the Forest Department and villagers only barely managed to turn the elephants back from some 20 km outside the city, averting what could have been a disaster of spectacularly tragic proportions. Once again, in a now annual feat, the foresters and villagers managed to beat them back to their patch of remaining forest sanctuary – only to gain a few months of relief before the elephants set forth once more. As with the Bombay leopards, the only action the government has taken so far is to pay some compensation to the victims and talk of translocating the herd. Meanwhile, the people are already taking things into their own hands: at least three elephants were killed last year – victims of poisoning or electrified fences.

Virtually all the remaining wild elephants in India face this problem of habitat loss and fragmentation to some extent, and conflicts with humans are common. One recent case was that of a big tusker which took to raiding crops outside the Kalakad–Mundanthurai Tiger Reserve in Tamil Nadu and killed two villagers before it was itself tragically brought down by a fatal dose of tranquilizers pumped into it in an attempt to capture and translocate it. But there was little else the beleaguered Forest Department could have done – if they had not made the capture attempt, people may have taken things into their own hands with graver consequences. And so the casualties mount on both sides of this conflict.

Going back to the question of whether the West can offer us any new ideas on dealing with the problem of wildlife in fragments of natural habitat embedded in a humanized landscape matrix: the above stories seem to highlight a certain contrast between the two societies' approaches. On the one hand, we have a country of 950 million people, most of whom lead a hand-to-mouth existence, with hardly enough land to support them – but willing to share that land with its wild denizens, even at a substantial human cost. On the other hand is a country with barely a fourth of India's population occupying a landmass three times as big as India, and a much higher standard of living for its people – yet even the smallest trespass by a wild animals brings instant and fatal retribution! The way many western countries have systematically targeted wild animal species perceived to be inimical to human interests (largely economical), often with little real evidence – like the wolf and the coyote in North America and the dingo in Australia – suggests a basic lack of respect for Nature and its wild denizens. This contrast is indeed a historical one: one can certainly make a strong case that Indian society has always been more protective of its wildlife than any western nation, the vast differences in population, resources and standards of living notwithstanding.

Some of my American teachers, while lecturing students on the loss of biodiversity and human pressures on wildlife, like to show a clipping from a film on human population growth. The segment shows a map of the world with a number of red dots scattered across it: the animated map depicts the distribution of human population across the globe, each red dot representing a population centre of over 1 million people. As the animation starts from a few thousand years ago and reaches the present time, one sees the map filling up with red dots: initially quite slowly, but at an accelerating pace in the current century. The film makes quite a dramatic illustration of human population explosion and, accompanied with data on global extinction rates of different species, reinforces the popular correlation between population growth and loss of biodiversity. The subtext is the fact that the equatorial belt, or the South, with the maximum number of red dots is also the region with greatest threats to biodiversity.

But what struck me most was another element which actually subverts the above popular analysis: the fact that the Indian subcontinent – as indeed most of Asia – has always supported a disproportionately larger share of red dots. Yet the extinction rates in this part of the world did not shoot up until the arrival of Europe in India! Another interesting region worthy of such a fine analysis is South America: that continent had a fairly high density of red dots before Columbus discovered it, but many of these blinked out following the arrival of

Europeans. And again, there is little evidence suggesting extinctions caused by native Americans: the overall positive correlation between human population growth and extinction rates appears here too only in the post-Columbus era! This pattern has already been pointed out in some critiques of the biological expansion of Europe – but it remains in the realm of the subversive, on the fringes of mainstream ecological discourse, and has not made it into many university syllabi.

This suggests that the differences are indeed cultural, with the less modern pre-western societies being more tolerant of wildlife than the modern western ones. And so, one may be reassured about our own historically superior record – at least in this respect – and search for the older ways that allowed us to maintain this coexistence. But I suspect the Indian scenario is (typically, one may say) much more complex, much more ambiguous, given the overt and subtle interplay of cultural, social and economic differences inherent in our multilayered society. If the above examples highlight coexistence in Indian society at a broader level, the following stories suggest streaks of arrogant intolerance at some specific sublevels.

The story of the Sunderban – deprived humans pitted against man-eating tigers in the world's largest mangrove swamp and tiger reserve – is all too sordidly familiar. Perhaps the final solution – one way or the other – to this intractable conflict will come from global warming and its attendant rise in sea levels! And that gives rise to a vision of the homeless humans of Calcutta stranded between man-eating tigers on one side and elephants on the other, both rendered homeless due to different human activities – one shudders at such an image! But tigers do occasionally turn to human flesh in other areas as well, even if not on the same scale as in Sunderban: while the much-lauded Project Tiger has so far succeeded in protecting many tiger populations, it has failed to provide more habitat for the increasing tiger population, and individuals are often forced to forage outside the reserves. Man-eating problems are not infrequent in some of the sub-Himalayan tiger reserves, notably Dudhwa, and the Forest Department has often been forced to kill some of these problem animals. One particular instance from the late 1980s, however, is stuck in my mind. One tiger had, over the course of a few months, killed as many as 16 local villagers, but no action was taken: perhaps the villagers were trespassing to collect firewood or engaged in another such illegal act, and so were either not vocal enough in their protests, or otherwise invisible to the authorities. But then the tiger made the error of picking its 17th victim from among the staff of the Forest Department – and was killed soon after. As one of my teachers at the Wildlife Institute of India commented wryly, it may seem that in some parts of India the life of one forest official equals those of 16 poor villagers!

Going further back, even if it was the arrival of the Europeans in India that triggered off major ecological damage, these external forces were, nonetheless, aided and abetted by many within our society. While the white hunter may have brought the guns, it was largely the local Maharajas, Princes and Nawabs who drove the cheetah to extinction and pushed the tiger and many other species to the brink. On the other side of the human/wildlife conflict/coexistence coin are the Bishnois of Rajasthan: now an enduring symbol of a traditional conservation ethic with great respect for wildlife, hundreds of Bishnois were massacred 300 years ago for protecting the trees around their villages – not by any European imperialist agency but by their own local king.

Where does that leave us then? On the one hand, we show higher tolerance for wildlife than the West, even bearing some human costs. But on the other, the West treats its citizens more as equals when it comes to wildlife conflicts – each victim is avenged, so to speak – while we seem to place our own in a hierarchy of values. This might lead one to say that in India wildlife has more value than (some) human life – a position many of the poorer victims already articulate. Perhaps, it is not too surprising to learn that in a society where some people have always been more equal than others, some animals might also be held more equal than some humans! The West, though it has its human hierarchies, is nevertheless more explicitly homocentric when it comes to dealing with nonhuman nature.

What lessons may one draw from such comparisons? Neither approach satisfies anyone who is interested in ensuring justice for both the human and nonhuman life forms sharing this earth. The Indian approach of tolerance and sharing allows nonhumans to coexist with humans to a greater extent – but many humans suffer. Even these older values and ethics respecting nature are now retreating under the combined assault of western consumerism and increasing human needs within the country. The West is still in the process of evolving a new set of ecological ethics based on a modern biological understanding of the origin and role of life on earth. We may be in a position to offer a model (religion-based) framework for such ethics, which can be expanded and elaborated with the help of modern ecological understanding. It is perhaps time we start actively offering the West some of our knowledge and solutions to its own problems, rather than passively waiting for them to come and help solve ours. For neither culture knows the best answers and both are groping for the light – albeit one more confidently and assertively than the other.

Environmental design

N. K. Waran

Institute of Ecology and Resource Management, School of Agriculture, University of Edinburgh, West Mains Road, Edinburgh EH9 3JG, Scotland, UK

Investigations of the behaviour of farmed animals kept in intensive conditions in Europe and America have indicated that their welfare is generally of concern. The inherent features of the modern systems for housing animals are confinement and restriction. Today's husbandry systems appear to be problematic for animals in that they prevent them from behaving in the way intended by nature. Consider, for example, the plight of the pig, a highly exploratory and socially sophisticated animal. When the sow gives birth, it is generally in a crate that prevents her from squashing her piglets. It also prevents her from building a nest, something she is highly motivated to do prior to parturition, and she is prevented from moving about, turning around and interacting normally with her piglets. Piglets are weaned at an unnaturally early age (3–5 weeks) and are moved into weaner accommodation that is typically cramped (0.2 m^2/pig) and barren (no bedding, no rooting substrate). They remain in grower accommodation until they reach slaughter weight, when they are often mixed with unfamiliar pigs and transported in cramped conditions to the abattoir.

Many of the animals in intensive systems exhibit abnormal behaviours which are sometimes stereotypic[1]. Stereotypies are defined as behaviours that are performed with monotonous regularity and are fixed in all details. Some researchers believe that they are mechanisms enabling the animal to cope with an environment that does not satisfy its expectations[2]. Others believe that they are associated with levels of feeding; pigs that are confined and fed low-maintenance diets are more likely to exhibit such behaviours than those fed higher levels. What does seem clear is that animals do not show these behaviours if they are kept in husbandry systems that are similar to the natural environment of their species.

In general, animal housing in the western world has evolved to suit the requirements of humans rather than of animals. The importance of the ease of cleaning and managing housing, and of handling, moving and observing animals, has quite correctly been catered for in most environments; but the actual behavioural needs of animals appear to have been compromised in many cases. Certain natural behaviours are not seen in the modern housing system, and more often than not animals perform abnormal or stereotypic behaviours. Behaviours such as feather-pecking in battery hens, belly-nosing in weaner pigs, and bar-biting in stalled sows are thought to be indicative of welfare problems in these animals, and are probably caused for the most part by the conditions under which they are kept.

Recently there has been a growing concern about the welfare of animals in intensive conditions, and with this, a growing interest in the design of so-called *ethologically sound* environments: environments that facilitate the species' typical behaviour and also enable that animal to be farmed effectively. There have been two broad approaches used in the past in designing environments that suit the behavioural needs of animals, or ethologically sound environments. The most well-known approach, and innovative at the time, was that used by the late David Wood-Gush and Alex Stolba (of Edinburgh, Scotland) and others in the designing of housing for pigs. This 'start-from-scratch' approach enabled the researchers to identify key features in the pigs' normal environment that appeared to elicit or release certain behaviours[3]. These key features were then incorporated into a new housing system for pigs called the Edinburgh Family Pig Pens. The second approach is one of modifying an existing environment through the improvement of the quality of limited space, either by artificial enrichment devices (such as food-balls and hanging tyres/chains for pigs) or by incorporating certain features thought to be important to the animals (such as dust-baths and laying-boxes for hens)[4–6].

Start-from-scratch designs

In general, it is often suggested that domestic animals have been heavily selected for certain features of domestication (for example, docility, trainability and a reduced fear of novel situations) and have 'adapted' in ways that suit the modern farming systems; in the process, they have lost the ability and the need to exhibit the behaviours their ancestors would have shown in their natural environments. In order to test this theory, in 1978, David Wood-Gush, Alex Stolba and colleagues released ordinary domestic large white sows and boars in a semi-natural environment in the Pentland Hills outside Edinburgh[3]. The Edinburgh Pig Park, as it was called, consisted of a 1.1 hectare site on the side of a hill which had forested and open areas, different types of grasses and shrubs, and various degrees of slopes. The group composition of 2–5 sows and 1–2 boars plus

Animal housing in the western world has evolved to suit the requirements of humans rather than of animals.... Certain natural behaviours are not seen in the modern housing system.

1–10 juveniles was adhered to, and the pigs were allowed to live and breed as normally as possible. Over a number of years, various studies on the behaviour of sows and piglets were conducted. These studies suggested, contrary to the opinion at the time, that pigs exhibited most, if not all, of the behaviours that had been recorded in groups of wild pigs. It was possible to identify certain key features in the pigs' environment that were important in the release of certain behaviours, such as rooting (i.e. digging with the snout) and defecation sites, and nesting sites. Based on this Stolba and Wood-Gush[3] attempted to recreate the 'natural' environment in a more restricted indoor area that could easily be managed. Although their aim was to develop an environment that allowed pigs to exhibit more natural behaviours, and to live in a more natural grouping, they also wanted to make this alternative style of housing more economically viable.

In 1980 the first Edinburgh Family Pig Pen was built at Easter Howgate Farm, south of Edinburgh. The Pig Pen housed four sows and their offspring. The sows remained there until all their breeding life, and were joined by a familiar boar 2–3 weeks after farrowing. Subsequent study of this system resulted in alterations in the original design, and a further two layouts were tested. Despite these alterations, there were still problems with the design. The monopitch roof of the building coupled with the cold Scottish weather was blamed for the high incidences of piglet mortality, and it was difficult to maintain an optimum group size of four sows since the addition of new individuals to the established group caused problems. However, the system did appear at the time to be economically viable – the number of piglets weaned was comparable with the better intensive systems, food conversion and growth were also comparable, and production records were good. The system did not take off commercially but the approach highlighted the importance of certain features for pigs, and showed that pigs could be kept in groups. The system is still being refined to this day: A research group in Aberdeen (Scotland) is working on a pen that operates on these lines, and a group in Switzerland (the home of the late Alex Stolba) is also developing the system.

There are, however, additional problems in this approach. Although the pigs were seen to exhibit certain behaviours in a more natural setting, no attempt was made to determine the importance of these behaviours for the animal. The need to show a behaviour, or the strength of the preference for an environmental feature, was not measured at the time, and the fact that the animals exhibited certain behaviours when given the opportunity to do so was taken by the researchers to indicate that these were important for the animals' well-being. This need not be the case since some behaviours may be considered as 'luxury behaviour': the animal may show it if it can but is not highly motivated to perform it if it cannot.

Recently, methods of assessing an animal's need to exhibit a behaviour have been developed[7]. If these methods are used in conjunction with the 'start-from-scratch' approach, a clearer idea of the importance of each of the key features may be gained.

Altering the existing designs

The second approach, that of modification or enrichment, involves changing something in an existing environment to encourage more natural behaviour. Examples of this can be seen in most European/American zoos, where man-made termite mounds have been built into chimpanzee enclosures to encourage more natural foraging activities and tool-use[8]. This approach has also been extended to farmed animals. Pigs have been provided with chains to manipulate, straw to root and balls to 'play' with. The addition of such objects has been claimed to reduce excitability, making the pigs easier to move and manage. It is claimed in addition that 'toys' help reduce the stressfulness of the often barren environment in which pigs live[5].

Modification of the environment can help solve the problems associated with some very intensive farming conditions. For example, in Europe and America over 90% of laying hens are housed in 'battery cages'[9]. These are so called because a large number of cages are placed in tiers within one hen-house. Layers are kept in groups of 3–6, with an individual space allowance of 300–450 cm^2 per bird. The cages pose problems for the birds since, although they are provided with adequate food and water, they are not able to fly, perch, walk about, peck the substrate, nest, or escape from each other.

There has been a widespread call for a ban on these cages but alternative forms of managing large flocks of birds have not yet been fully developed. The Edinburgh modified cage is an attempt to improve the hens' welfare by enabling them to live in larger cages, fitted with perches, nest boxes and dust baths. Production is above average in these cages, and all facilities are heavily used. Feather, foot and claw damage is also reduced. It is felt that further development of such modified cages would lead to vast improvements in hen welfare.

In conclusion, environmental design is a broad subject encompassing the physical, social as well as developmental needs of the animal. Designing animal environments to take these needs into consideration, as well as the needs of the humans operating the system, is a difficult task, and in order to do it effectively we must have an understanding of the impact the environment can have on the well-being of the animals. A logical sequence of events leading to a new system would, therefore, be: (i) define the behavioural requirements; (ii) determine if existing systems contravene these requirements and, if so, determine the consequences for the animal; and (iii) if there is a need following (ii), then a new system(s) requires to be designed taking into account behavioural requirements and other management and economic considerations.

Stereotypies in the stabled horse: Causes, treatments and prevention

L. Winskill, N. K. Waran, C. Channing and R. Young

IERM, University of Edinburgh, Kings Buildings, West Mains Road, Edinburgh, EH9 3JG, UK

The environment for most stabled horses is far removed from that of its wild ancestors. The horse is a social animal, and in natural groups in the wild it lives in harems, usually consisting of one stallion, a few mares and all their offspring up to two-years old[1]. They restrict their movements to a specific home range within which the major requirements are food, water and shelter. Home ranges of free-ranging horses vary greatly in size and are correlated with resource availability[2]. In contrast, the stabled animal is removed from this normal open range and often deprived of social contact. Many performance horses (e.g. racehorses, show jumpers, etc.) in Europe and also in India are confined for up to 24 h a day with the exception of short periods of time reserved for exercise, and others are turned out to pasture for merely a few hours a day.

This restricted environment often has a significant effect on the normal time budget of the horse as it can no longer spend the majority of the day foraging and expending energy looking for suitable resources[2]. Feeding with concentrated food also has consequences for the horse, since it eliminates the additional time that confined animals can occupy themselves with ingestion and manipulation of food[2]. Free-ranging horses spend a high proportion of their time grazing. A study by Boy and Duncan[3] on free-ranging feral Camargue ponies during spring and summer revealed that 57.5% of their time was spent grazing. This proportion of time is likely to be greater in the winter months, when grass is scarcer. In the stabled environment, however, if fed on hay, horses will spend 40% of their day eating, which is reduced by one tenth if fed chiefly on concentrates[4].

As already highlighted, the stabled horse is often deprived of social contact, both visual and physical. The design of the majority of housing for horses does not take into consideration their behavioural needs, often enclosing the animal in small individual loose boxes or stalls, where it is deprived of social contact and exercise. Rees in her book *The Horse's Mind*[1] describes the confined horse as being like 'a fish out of water'. She notes that many learn to accept confinement, but others kept in these unnatural conditions, deprived of freedom,

exercise and companions, become excitable and irritable. It is in such conditions that behavioural problems may arise.

This article discusses the incidence of behavioural problems of the stabled horse giving examples of those most commonly found and how they might be treated and prevented from occurring. More general factors relating to the occurrence of these problems are also mentioned.

Behavioural problems and their incidence

Stabled horses can be seen to exhibit a variety of behavioural problems or 'stereotypies' such as crib-biting, weaving, wind-sucking and wood-chewing. Such behavioural anomalies are often wrongly referred to as 'vices', a term which implies that the blame should be attributed to the horse itself and not to the management procedures adopted or the housing imposed by humans[5,6]. An example of such misuse of terminology is highlighted in the paper by Krzak *et al.*[7] regarding wood-chewing of stabled horses, in which they state that: 'The owner of a wood-chewing animal must absorb the costs of replacing damaged fences and stalls and of preventative measures such as covering wood surfaces with metal, wire or taste repellents. For these reasons, horses that exhibit this 'vice' are of reduced value and may not be saleable'. The welfare of the animal is not mentioned; merely the cost and inconvenience brought upon the owner are highlighted. Fraser and Broom[5] believe that such attitudes have been an important factor in the perpetuation of many systems which result in poor welfare, while Luescher *et al.*[8] suggest that the term 'vice' should be reserved for nuisance behaviours related to temperament such as biting, kicking and rearing.

Some behavioural problems of the stabled horse are more accurately referred to as stereotypies, e.g. 'repetitive, invariant behaviour with no obvious goal or function'[9], and are indicative of a situation in which the animal lacks a certain degree of control over its environment[5]. Stall-walking, crib-biting, wind-sucking, weaving, swaying, pawing, stall-kicking, head-shaking, head-nodding, crib-whetting and tongue-dragging are behaviours that have received detailed description, and are examples of movement sequences which horses repeat with very little variation in form[6]. Stereotypies have been recognized and much researched in many confined animal species, for example, zoo animals[10], pigs[11], sheep[12] and domestic fowl[13], but as emphasized by Rees[1], such behaviours in stabled horses seldom receive the same attention.

The proportion of horses exhibiting stereotypies varies among studies, which makes it difficult to assess the extent of the problem. A study by Kennedy *et al.*[14] revealed that 18.4% of the 49 horses observed at two riding schools and four private livery yards showed clearly recognizable stereotypies. This figure was even thought to be an underestimate, as the staff at the stables described more horses as stereotypy performers than those identified during observation. Kiley-Worthington and Wood-Gush[15] stated that in some of the racehorse stables which they visited, all the horses were exhibiting stereotypies, and in another stable 26% of the horses were seen to perform a stereotypy within only half an hour of observation. A recent article[8] quoted that over 15% of domesticated horses exhibit stereotypies.

These figures, however, should all be questioned due to the small sample sizes involved in the studies. In an investigation involving 1035 thoroughbred horses aged 3–8 years in Italy, Vecchiotti and Galanti[16] report the incidence of cribbing, weaving and stall-walking as 2.4%, 2.5% and 2.5%, respectively, of all behaviours. Similarly, a recent study carried out on 21 thoroughbred horses in the north and centre of Italy showed that 67 out of 1180 (5.7%) horses showed a behavioural problem[17]. These lower percentages are perhaps a better representation, as a larger number of horses were analysed. However, until a study is undertaken comparing the incidence of stereotypies between differing breeds, ages and sexes of horses with varying types of yard (e.g. breeding, racing, livery or riding school), it will remain difficult to quote an accurate figure representing the extent of occurrence of stereotypies in the stabled horse. Another factor which will have an effect on studies involving survey questionnaires distributed to horse owners is a reluctance on the part of some owners to admit that their horse is a stereotypic performer (as this often decreases the value of the animal), leading to underestimation of the affected numbers.

Stereotypies: examples, causes and treatments

Quantitative evidence relating to the causal factors of stereotypies in stabled horses is very scarce in the scientific literature, the majority being purely anecdotal in nature. With the exception of more recent studies[17,18], research in this area has involved either small sample sizes[19] or has consisted of a collection of individual case studies[14]. This lack of evidence implies that the causes of abnormal behaviour are still unclear, and more research is still required.

Wood-chewing

Wood-chewing is a normal component of a free-ranging horse's feeding behaviour, especially when preferred grasses are less abundant during late autumn and winter[20]. Wood-chewing is, however, a common problem in the stabled environment, where a horse may chew 0.5 kg of wood a day[5]. Coupled with the financial burden on

the owner to replace fences and stable boards, wood-chewing can also cause damage to the animal itself, largely by causing excessive wearing of teeth[21]. It can pose more serious consequences such as gastrointestinal disease[22], and small splinters of wood or nails may puncture the oesophagus or mouth[5,21], and may also lead to the formation of phytobezoars or enteroliths[21].

The association of wood-chewing with pelleted feeds has been well documented[22]. The exact cause of wood-chewing associated with these feeds is unknown although reduced cecal pH and relative lack of fibre or 'chewing time' or both have been suggested[5,22]. The horses' natural diet consists of an almost continuous consumption of roughage, a large amount of which is required by the system for proper digestive fermentation. Willard *et al.*[19] undertook an experiment to determine the effect of diet on cecal pH and feeding behaviour of horses. For the study, three fistulated horses were used, and their dietary treatments were hay, concentrate and concentrate plus cecal infusions of Na_2CO_3. Horses fed on hay were found to spend significantly more time eating feed and significantly less time chewing wood, in coprophagy, in searching for feed and in standing than those receiving the concentrate diet. The amount of wood chewed per day was significantly greater for horses fed on concentrate diet and the Na_2CO_3 infusions appeared to reduce the amount of time spent chewing wood by the concentrate-fed horses, but the difference was not significant. They state that their results may indicate that increased cecal acidity and a narrowed acetate–propionate ratio, as was noted with the all-concentrate diet, influences the horse's desire to chew wood and practice coprohagy.

Doubts, however, have to be raised about the significance of these results, firstly due to the small sample size used (three horses), and secondly as only two feeding regimes were used: 8 kg of mixed grass legume hay and 6 kg of a sweet feed mixture fed at 12 h intervals. A combination of hay and concentrate may have been more appropriate to normal feeding practices. Another factor is that the authors do not mention whether these quantities of hay and concentrate represent the same percentage of body weight, which will have an effect on the results.

The results of this experiment contrast with those of a study carried out by Jackson *et al.*[23], where horses were subjected to one of the three treatments. In the first, the animals were fed long-stemmed alfalfa hay twice a day; in the second they were fed alfalfa cubes twice a day, and in the third they were fed alfalfa cubes three times a day. Both the cubes and hay were fed at 2.5% of body weight per horse per day. It was shown that there was no difference in the amount of wood chewed, despite the fact that animals in treatment 2 spent less time eating than those in treatments 1 and 3, and the cubed alfalfa would have contained less roughage than the long-stemmed hay (C. Morgan, personal communication). The difference between the two studies could possibly be explained by the fact that horses in the latter experiment were able to socialize, whereas those in the former were maintained in metal stalls, where boredom could also be a factor predisposing the horses to chew wood. Furthermore, reduced cecal pH and lack of fibre or chewing time[19, 22] suggest that the degree of intestinal fill provided by the diet should also be investigated.

Exercise of the stabled horses is also believed to reduce wood-chewing by reducing boredom[7]. A study undertaken by Krzak *et al.*[7] demonstrated that horses chewed more wood when they did not receive exercise than when they received 45 min of exercise on a mechanical treadmill followed by a further 45 min in a paddock with bare soil in either the morning or the afternoon. The greatest amount of wood-chewing occurred during the late night and the early morning when distractions were minimal. The authors believe that this provides some support for the boredom theory, and also suggest that hunger may have been associated with wood-chewing in this particular study, as its incidence was seen to increase several hours after the afternoon feed. Feed restriction has already been found to be related to the performance of oral chain manipulation in tethered gilts[11], stereotyped pecking at nonfood objects in broiler breeders[24] and abnormal behaviours, including chewing wood in individually penned sheep[12]. Frustration of feeding motivation has been suggested as an underlying cause of oral stereotypies in pigs[25]; however, in this particular study[7], wood-chewing did not appear to be related to the time of feeding, as oral contact was not associated with the afternoon feeding and did not increase immediately before or after the morning feeding.

Finally, weather has been associated with the amount of wood-chewing. In the study by Jackson *et al.*[23], the incidence of wood-chewing was seen to increase, in both wet and cold weather.

The most common method employed to prevent wood-chewing is to cover all wood surfaces with a noxious substance such as creosote[5], carbolium or lemon-flavoured oils[22]. Such practices, however, only prevent the performance of the behaviour and fail to identify the underlying cause. It is obviously important that the animal receives a correct diet in terms of protein and energy, and should contain more than 50% roughage, or there will be a risk of failing to satisfy its needs for fibre fill and chew time[3]. If it is essential that the horse be confined, adequate exercise should be given, and attempts made to relieve boredom; for example, by providing a companion animal such as a goat[26]. Providing a sheep as a social companion proved successful in an experiment looking at social facilitation in pigs, in which one of the treatments involved housing the animals in isolation[27]. The inclusion of toys has also been suggested[26]. Since wood is a natural component of a

horse's diet, the problem cannot be entirely eliminated[26].

Crib-biting and wind-sucking

Crib-biting and wind-sucking are probably the most easily recognizable sterotypies in the stabled horse[14]. Wind-sucking involves opening the mouth, contracting the pharyngeal muscles, flexing the neck muscles and swallowing air, usually making a characteristic grunting noise. Crib-biting (or cribbing) is characterized by the horse resting its upper incisors on a solid object such as a door or a manger. It then leans back, arches its neck and engulfs a bolus of air (aerophagia)[28,29]. In rare cases, the mouth may be placed against the knees or cannons[5]. Cribbing is usually associated with stabled horses; however, some will crib when turned out to pasture[28]. Both crib-biting and wind-sucking can be detrimental to the health of the animal. Crib-biting can cause excessive wear of the incisor teeth, in some instances they may be worn down to the gum line[26,27], and both crib-biting and wind-sucking can cause the musculature of the throat to increase in size, and make the animal more susceptible to flatulent colic[5,29]. Horses which practise aerophagia intensely may reduce their intake of feed, which will ultimately lead to a deterioration of their physical condition[5].

Heredity has been thought to play a role in the frequency of stereotypies. A survey was undertaken by Vecchiotti and Galanti[16] in which 80 trainers were interviewed on the occurrence of anomalous behaviours, involving a total of 1035 thoroughbred horses. The incidence of crib-biting (also weaving and stall-walking) in related horses was found to be higher than that in the surveyed population. The authors suggested that this was due to the involvement of inheritance in each of the three behaviours. However, as discussed by Broom and Kennedy[6] this could simply be due to the fact that many related horses, particularly thoroughbreds, are kept in similar housing conditions which may give rise to the performance of stereotypies.

In other species, it has been shown that stereotypies are associated with opioid activity, which may have the effect of quietening the performer[30]. When naloxone is administered to stereotyping sows, the behaviour is stopped[5]; narcotic antagonists were also found to prevent crib-biting in horses[29]. Baseline β-endorphin levels in cribbing horses were found to be half of those in non-cribbing controls. This was thought to be due to cribbing horses having an impaired release of β-endorphin, which in turn increases the sensitivity of opioid receptors (Gillam *et al.*, 1994, unpublished).

In a study investigating the effects of different diets on the frequency of cribbing behaviour, feeding grain or sweetened grain rations was seen to cause a significant increase in cribbing frequency (Gillam *et al.*, 1994, unpublished). This is thought to be due to the palatability of these particular rations, since palatable food has been shown to release β-endorphins and enhance stereotypic behaviour patterns in the horse[29]. Kennedy *et al.*[14] undertook a study in an attempt to discover factors relating to both management, and horses' characters which may be linked to the development of stereotypies. Many of the individual animals involved who performed crib-biting were seen to exhibit this behaviour around the time of feeding. A proportion was seen to exhibit crib-biting post-feeding, which could possibly be related to the palatability of the food[29]. Heifers tied up in stalls have also been found to spend most of their time performing stereotypies 2–4 h after feeding[31]. Other bouts of crib-biting in this study, however, were linked to the anticipation of food prior to feeding[14]. Pigs exposed to an intermittent delivery of food with a chain in front of them were seen to develop stereotypic chain manipulation in the interval between food deliveries, and displayed a lower plasma cortisol level than in the absence of the chain, suggesting a stress-reducing role of chain manipulation when the pigs were anticipating the delivery of food[32], which could possibly be an explanation for the increase in the frequency of crib-biting seen in horses prior to feeding time.

Feeding has been associated with the performance of oral stereotypies in a number of other species; for example, wire-chewing in commercially housed rabbits and bar-biting in heifers[31], sheep[33] and pigs[11]. When on high feed intakes, tethered gilts performed a lower incidence of repetitive behaviours such as bar-biting and chain-chewing, which increased when fed a small ration[11]. Bar-biting, crib-biting and other stereotypies are more frequent in the absence of straw or other manipulable material[34], so it appears that the type and bulk of forage offered as well as the ability to manipulate are important[5].

Traditionally, the control of crib-biting and wind-sucking has been directed towards preventing the behaviour by mechanical or surgical techniques[26]. The cribbing strap is the most commonly used mechanical control device. This consists of a 4 cm leather strap fastened around the throat, tightly enough to make arching of the neck uncomfortable, but not so tight as to interfere with respiration[5,28]. In some designs, there is a metal 'gullet-piece' which has a recess into which the windpipe fits, or a pressure plate containing one to three sharp spikes[5,28]. These straps can be buckled so tightly that they interfere with normal eating, and in one noted case a tightly applied strap was associated with acute chondritis of the larnyx[28]. Another preventive measure consists of a hollow cylindrical perforated bit, which prevents the animal from making its mouth airtight[5].

Surgery has been performed in both wind-sucking and crib-biting horses[5,28,35,36]. It is, however, a very drastic

measure to undertake in order to prevent behaviours caused largely by management practices imposed by man. The success rate of operations is also fairly low, and the majority of animals responding to these methods of prevention are those which have not practised the anomaly for long periods[5].

Attempts such as surgery or the use of a cribbing strap when used to prevent the performance of a behaviour prevent only its manifestation without eliminating the causal factors involved. Such measures may cause additional frustration for the animal, which may perform another stereotypic behaviour that it is not restricted from expressing, further compromising its welfare. As recommended for animals performing wood-chewing, the housing and management of the horse needs to be improved. A simple task such as feeding at random times throughout the day may help in reducing the expression of crib-biting and wind-sucking which occur prior to feeding. However, in their most severe forms, wind-sucking and crib-biting may continue to be performed when turned out to pasture (personal observation), emphasizing the persistence of stereotypies once developed[9]. In such circumstances where the behaviour continues despite recommended changes in feeding and other management practices, such as the provision of social companionship and increased exercise regimes, the use of narcotic antagonist drugs such as naloxone and naltrexone, may play a role[29], although this could be argued by some to be no better than surgery or physical restriction.

Weaving and stall-walking

Weaving and stall-walking have been described as locomotor activities which have become fixations[26]. The main feature of weaving is that the horse swings the head and neck from side to side, whilst shifting its weight from one foreleg to the other[5,22]. This is similar to the rocking behaviour shown by monkeys in captivity[5] and in institutionalised humans[9]. Head-swaying has also been observed in singly caged rabbits, where its function has been suggested as a mechanism to relieve boredom[37]. Stall-walking describes a form of stereotypic pacing, in which the horse constantly walks around the perimeter of the stable. It is thought to resemble weaving as both behaviours involve accurate precision and repetition[5]. Both activities can lead to weight loss, but particularly 'stall-walking', where vast quantities of energy can be depleted[5,26]. Stall-walking can also cause flexion of the spine, especially if the area available to the animal is particularly small[5]. Apart from its aesthetic appearance, the performance of weaving is disliked by horse owners as it can cause uneven musculature development in the neck, which can have an effect upon performance.

There is little information available regarding the causal factors of these behaviours, although frustration, boredom due to lack of variety in the environment and lack of exercise have been suggested[5,26]. Lack of variety in the environment has been found to be a contributing factor in the occurrence of stereotypic pacing in captive-felids, as the frequency of this behaviour in captive leopards was found to decrease significantly after enrichment of the environment[10]. In many captive carnivore species, stereotypic pacing is thought to be caused by the build-up of frustration due to being unable to perform predatory behaviour[10]. Stereotypic pacing in captive American black bears was seen to reduce dramatically when food was hidden in manipulative objects[38], and in captive polar bears expectation of food was found to influence the frequency of pacing behaviour[39]. Feeding could also be one of the contributing factors influencing the onset of stall-walking in the stabled horse, but there is no evidence to suggest this, more research obviously being required in this area.

There are not many measures undertaken to prevent these behaviours. A metal grate is often attached to the stable door to prevent horses from weaving, but the most obvious method of preventing an animal from developing these stereotypies would be to turn them out to pasture, as they appear to be linked to the need to exhibit locomotory behaviour.

General factors relating to the occurrence of stereotypic behaviours

As previously mentioned in relation to crib-biting and wind-sucking, inheritance is thought to play a role in the performance of stereotypies in horses. There is, however, little evidence to accompany this hypothesis with the exception of the survey of thoroughbred horses in Italy by Vecchiotti and Galanti[16], in which they revealed a genetic component in the causation of crib-biting, weaving and stall-walking. A study in Japan[6] came to a similar conclusion. This is certainly apparent in dogs, in which particular breeds seem to be predisposed to abnormal behaviours (e.g. whirling in Bull Terriers)[8]. Kiley-Worthington[40] also notes that stereotypies seem to be more prevalent in thoroughbred and Arab-type horses, which suggests a genetic factor, although she suggests that this could be due to the restricted environments that these 'warm-blooded' breeds are kept in.

It has been proposed by a number of authors that stereotypies can be learnt by imitating neighbouring stereotypic performing animals, particularly between mothers and their offspring[5,8,40]. Stereotypic behaviour in bank voles was more rapidly developed in those individuals which were visually exposed to a demonstrator already performing stereotypies[41]; similarly, neighbour-

ing stereotyping sows were seen to influence the amount of stereotypic behaviour performed by tethered gilts[42]. However, in an experiment designed to determine whether a horse could learn the position of grain in one or two buckets by watching another horse, Baker and Crawford[43] showed that no observational learning was demonstrated by the animals. The reason why neighbouring horses develop stereotypies is, therefore, more likely to be as a result of them being kept in the same inadequate environment rather than due to their ability to copy.

Abrupt weaning has also been suggested as a possible factor relating to the onset of the performance of stereotypies, as a survey of thoroughbred breeding farms in Italy showed that 23.8% of horses less than two years old showed abnormal behaviour[17]. These behaviours were seen to commence immediately after the post-weaning period, and as the animals were turned out until the training period, the authors believe that the abrupt weaning could be a stressor for the foals, which could in turn lead to behavioural problems.

The management of young horses in training was the major factor linked to an increase in the prevalence of abnormal behaviour in a survey sampling the largest uniform population of thoroughbred horses yet to be studied, in relation to the performance of weaving, box-walking, wind-sucking and crib-biting[18]. The same study found that the risk of horses performing abnormal behaviour increased when the total number of horses on the yard was less than 75, in box designs which minimized social contact between horses, when bedding types other than straw were used, and when the amount of feed was less than 8.8 kg per day.

Conclusion

In order to prevent the development of stereotypies in the stabled horse, an appreciation of the type of social and physical environment the horse has evolved to live in is obviously required[40]. This knowledge should also be taken into consideration in future housing design; for example, by providing more space and social companions in the form of group housing. It will, however, probably prove difficult to persuade owners to take into consideration their animal's behavioural requirements as horses are very valuable animals and are too often 'wrapped in cotton wool'. This is highlighted in a survey of thoroughbred breeding farms in the north and centre of Italy, where stallions were found to perform a higher frequency of abnormal behaviours than mares[17]. The authors suggest that the reason for this is the different management of the two sexes. This is probably true, since stallions are worth vast sums of money and are nearly always kept in single stables, with no access to pasture for fear of theft or injury. Horse owners, therefore, need to be educated about the psychological causes of stereotypies, as most are treated only because they are not aesthetically pleasing and may decrease the value of the animal.

If horses are to be confined, then every effort must be made to prevent the occurrence of these abnormal behaviours using suggestions outlined in the article; for example, by providing hay *ad libitum*, providing a social companion and adequate exercise. There is also scope for the provision of enrichment devices such as the 'Edinburgh foodball', which has already proved to be a successful foraging device for pigs[44].

ICI India Limited

ICI India Ltd. is one of the leading chemical companies engaged in diverse businesses including Pharmaceuticals, Paints, Explosives, Rubber Chemicals and Surfactants. The company is presently looking for:

SCIENTISTS

for its prestigious R&D Centre located at Thane near Bombay. The Centre has excellent facilities and high calibre staff, and undertakes national and international projects. Applicants should have a Ph.D in SYNTHETIC ORGANIC CHEMISTRY with relevant postdoctoral experience. Exposure to Industrial research would be an advantage, but is not essential. Only persons with proven track record of excellence should apply.

The company offers professionally challenging and stimulating work environment, performance-based career growth & an excellent remuneration package including company leased housing.

Please apply within 10 days to: The Personnel Manager, ICI India Ltd., P.O. Box 87, Thane-Belapur Road, Thane - 400 601, Maharashtra: Fax: (022) 763 2889.

Seamless chemical engineering science: The emerging paradigm*

R. A. Mashelkar

I consider it to be a matter of great honour that I have been asked to deliver the ninth P. V. Danckwerts Memorial Lecture. Danckwerts' contributions to the evolution of Chemical Engineering Science (CES) are monumental. He set the pace and the tone and defined the features of CES in the early fifties through his path-breaking and incisive contributions. His work has continued to inspire generations of chemical engineering scientists (CE scientists). I certainly happen to be one of them. It is, therefore, a special privilege that I have this opportunity to pay my own tribute to Danckwerts. Today I wish to speak to you on an emerging paradigm – the seamless chemical engineering science.

How did Danckwerts himself view CES? I searched and found a statement in his presidential address delivered to the Institution of Chemical Engineers almost three decades ago. He said: 'I shall use the phrase Chemical Engineering Science to mean the aspects of science developed by chemical engineers for their own purposes in fields not covered by other branches of technology'[1]. He also went on to alert us: 'It will be a great mistake to think of the content of chemical engineering science as permanently fixed. It is likely to alter greatly over the years in response to the changing requirements of industry and to new scientific discoveries and ideas for their application'. He was absolutely right. I wish to refer to those explosive advances in science which are reshaping our lives. I also wish to emphasize how these advances in adjacent sciences will force us to reconceptualize CES of tomorrow. I particularly want to focus on the merging boundaries between CES and the adjacent sciences and also on the need to build new bridges with our neighbours.

We look around and see that discrete boundaries no longer exist between various natural sciences such as physics, chemistry, biology, mathematics, etc. Let us remember that the 1985 Nobel Prize for chemistry was actually awarded to two mathematicians! Take even subdisciplines such as inorganic chemistry, biological chemistry, organic chemistry and physical chemistry. The conceptual boundaries between these disciplines have already vanished. The Nobel Prize winning work of Lehn[2] was a testimony to this realization.

Is only science going borderless? Of course not. The borderless world has already dawned on us. Borderless organizations are here to stay too. I wish to quote from the speech by Jack Welch, the Chairman and Chief Executive Officer of General Electric (GE), whom we all respect for his dynamism and vision. In his lecture on 'Global Competitiveness' delivered last month, he talked about GE's strong commitment to the boundaryless behaviour and said, 'Boundaryless is the language, the behaviour definer, the culture, the soul of a true global enterprise. It ignores geography, borders, accents, currencies, and unites people of all cultures'. When asked about what happens to those GE people who did not accept this boundaryless behaviour, he responded by saying, '(we) tell them they have to change, or else if they don't change, they have to part company with us. And we do have them part company – lots of them over the question of boundaryless behaviour, of being open'. Strong words indeed – but it shows the way it works in industry. Why does it do so? Let me answer this.

Successful commercialization of modern scientific discovery today demands cross-disciplinary collaboration between scientists and engineers from different disciplines. Advances are generally the sum total of numerous creative ideas and interdisciplinary cooperation. In industry, individuals with diverse scientific and technical backgrounds tend to work together in a mission mode. The driving force for industry is continuous innovation to displace one's own product by oneself – with the well-known fear of someone else displacing it otherwise for them. The concept of interdisciplinary research and development has not gained as much ground in academia as one would have wished. And this is really sad because innovation is not a unidimensional process. It is comparable to the intermeshing gears of a clock. The challenge before us is to make this intermeshing happen.

Why did I decide to speak on this topic? I find myself in an interesting situation. I head the National Chemical Laboratory (NCL) in India. I have to deal with multidisciplinary teams of over 500 research scientists and engineers. I find myself communicating with physical

R. A. Mashelkar is in Council of Scientific and Industrial Research, New Delhi 110 001, India.

*Ninth P. V. Danckwerts Memorial Lecture presented at Glazier's Hall, London, UK, 9 June 1994.

Reprinted from *Chemical Engineering Science*, Vol. 50, R. A. Mashelkar, 'Seamless Chemical Engineering Science: The emerging paradigm,' page 1–22, 1994, with kind permission from Elsevier Science Ltd., The Boulevard, Langford Lane, Kidlington OX5 1GB, UK.

chemists, organic chemists, inorganic chemists, etc. I deal with molecular biologists, biochemists, bio-organic chemists too. I also deal with materials scientists, applied mathematicians, NMR experts and so on. Our CES group is placed amidst all these groups and it has to interact with all these disciplines. This interaction is crucial to meet NCL's charter, which is to develop globally competitive products, processes and technologies. Interestingly, we have found that we succeed in this only when we come together as a team, leaving aside all the conceptual and cultural barriers between different disciplines. But I must also honestly admit that I have found it to be a hard act to put together. I thought I would share the agony and ecstasy that I have experienced during all these years of going 'boundaryless' with you.

But before I begin to address the principal issues, I must put the role of an engineering scientist, as I see it, in perspective. I would like to give an analogy with the medical school. We have there basic scientists, who generate new knowledge, but it is knowledge for its own sake. Then we have the hard-core practising clinicians, who use the established tools in their everyday practice. But in between these two communities, there are those academic clinicians. They are the ones who understand the language of the basic scientists and they are the ones who know the demands of the profession, as reflected by practising clinicians. What these academic clinicians do is to use the methods of science to develop new tools and new paradigms that the practitioners would find most helpful. They also communicate the needs of these practitioners to the scientists. The academic clinicians thus play this great role of facilitators. To my mind, a CE scientist is like an academic clinician, a facilitator. His task is to look at the continuous advances that take place in basic sciences such as chemistry, biology, physics, etc. He would harness this knowledge to develop new tools, which hard-core chemical engineers would put to use. The richness of our chemical engineering profession, therefore, depends very critically on the vitality of the CE scientists and also on the rich variety of skills, tools, etc., that they bring into the profession.

I will give my personal perceptions about the following issues. What is the emerging relationship between CES and adjacent disciplines? What driving force is shaping this relationship? How do we respond to the explosion of knowledge in adjacent sciences? What will be the new role of a CE scientist *vis-à-vis* chemical engineering and other disciplines of engineering and sciences? What new tools and techniques can we adopt from other disciplines and, in turn, what could we give to other disciplines? Danckwerts practically defines Chemical Engineering Science as 'applying methods of science to distinctive chemical engineering problems'. Is this definition valid anymore? What should be the new definition?

A word about how I have organized my lecture may be in order. This is certainly not a lecture on 'new frontiers in CES', since these frontiers have been widely discussed and elaborately defined by the Amundson report[3]. I am also not getting involved in a discussion of the 'core' vs 'frontiers' issue, which has again been dealt with by some of our very best scholars and thinkers[4,5]. I am also not speaking about the future of fields such as mass transfer, reaction engineering, applied thermodynamics and so on. Furthermore, although I want to deal with the issue of merging boundaries with other disciplines, I am not going to create distinct boxes such as CES–physics interface, CES–biology interface, etc. To me, the boundaries between other disciplines have already vanished. I will, therefore, deal with only some 'generic issues' that should be of concern to us.

This lecture is admittedly a narrow view from a window. I also have the inescapable personal bias, which might show through the examples and the illustrations that I have chosen to give, and also the recommendations that I have dared to make despite my limitations. However, I thought it is worth putting these thoughts on record, since this is the time to do it. Tomorrow might be too late!

Nonlinear dynamics – New interdisciplinary challenges

Complexity and nonlinearity reside in much that a chemical engineer encounters. His ability to acquire new tools and knowledge by exploiting the contemporary advances in physics has undergone a sea change in recent years. A wide variety of features ranging from steady state to multiple steady states to oscillations to chaotic dynamics and spatiotemporal patterns[6,7] have become more commonplace observations. The advent of increasingly sophisticated experimental tools to detect and analyse microscopic events, new methods of mathematical analysis and computational advances have further accelerated the development in this area.

The discovery of dynamical chaos has opened up many exciting possibilities with wide-ranging implications in natural sciences and engineering sciences, CES being no exception. The usefulness of chaos comes from the fact that it is a collection of many sets of orderly behaviour, none of which dominates under normal circumstances. At first sight an engineer shies away from chaos, because he finds it unreliable, uncontrollable and, therefore, unwanted. However, the challenge for an engineer is to control chaos and make it manageable, exploitable and, in fact, invaluable.

We ought to recognize that the special problems encountered in CES have to be viewed within a grand universal framework. Indeed, forms of quantitative universality have been found to occur in chaos so that it

now seems that studies on a case-by-case basis may not really be necessary. Thus, for example, the routes to chaos by the system when a control parameter is varied follow specific mechanisms like period-doubling, intermittency or crisis. In each of these cases the onset has a typical diagnostic measure. For instance, in the case of period-doubling bifurcation, the ratio of successive bifurcation points tends to converge to a universal constant, now popularly referred to as the Feigenbaum number. The realization that the behaviour of complicated physical systems can be analysed on the basis of very simple nonlinear equations indeed suggests that the complexities of the real world may arise from underlying simple causes. Furthermore, for a system exhibiting chaotic dynamics, an important property is its sensitivity to its initial conditions. Even an infinitesimally small difference in specifying initial conditions accurately may lead to a catastrophic growth in the error. This means that one can make near-accurate short-term predictions about the system behaviour but certainly not long-term. This has profound significance in many CE systems that we deal with.

Multidimensionality, intermittency and coupling are conditions that are frequently met in many CE systems. Therefore, such systems become serious candidates for exhibiting chaotic behaviour. The subtleties brought out by the chaos theory pervade a number of situations, covering complex reactions in a CSTR, bubbling from a submerged orifice, mixing and so on. Let me illustrate the point further by giving some illustrations.

Chemical systems provide excellent prototype systems for studying nonlinear behaviour, since they offer a variety of convenient settings ranging from the simple to the more complex[8]. In this context, an open, well-stirred system (CSTR) following nonlinear kinetics and involving a few chemical species forms a good basis for the study of low-dimensional nonlinear dynamics and steady-state behaviour. Common examples of systems with nonlinear kinetics involve reaction mechanisms with autocatalytic or nonisothermal feedback features[9]. It is interesting that an early experimental observation of chaotic dynamics was reported by Schmitz *et al.*[10] for the now famous Belousov–Zhabotinskii oxidation reaction scheme. Continued theoretical and experimental investigations have revealed newer and newer nonlinear dynamical and bifurcation patterns. Attention continues to be given to analysing the behavioural patterns of systems of interest to chemical engineers, say, for example a nonisothermal consecutive reaction $A \rightarrow B \rightarrow C$ occurring in a CSTR[11,12].

Open systems operating far from equilibrium produce a very rich behaviour. Advances in modern instrumental methods such as photoelectron, field electron and field ion microscopy reveal the ensuing structures with higher and higher resolution power. Oscillatory, chaotic and spatiotemporal concentration patterns of the adsorbed species for carbon monoxide oxidation on platinum surfaces for various types of catalysts, including supported wires and foils, are available[13]. Specific domains of the catalysts show synchronization as a result of heat conduction through the supporting material or even through the gas phase. Propagating reaction–diffusion fronts (diffusion coupling) also leads to such synchronization. The important keywords are, therefore, coupling and synchronization.

Due to the coupling between complex kinetics and transport processes in CE systems, a wide range of dynamic behaviours can be observed. Possibility of dynamic pattern formation by coupling at a larger scale was demonstrated by Arce and Ramakrishna[14]. The dynamic behaviour and the stability of such systems and its linkage to the understanding of formation and propagation of long-range dynamic patterns (including travelling waves in reactors) is obviously a hot topic for study. True CE culture is entering into the field; the contributions by Fox and Villermaux[15] on the role of micromixing (a typical CE paradigm) in controlling the existence and nature of oscillatory patterns is a good example.

The development and study of nonlinear systems has been confined to study of low-dimensional systems so far. But a CE scientist has to look far beyond this. He has to deal with systems involving time delays (something that an electrical engineer may not experience in his systems) or those that are modelled by a set of partial differential equations. The time delay elements, for instance, are inherent in many CE operations, such as in feedback loops of well-mixed processes. The effect of their presence in the observed dynamics of a nonlinear system can be quite dramatic and they require attention.

Consider the classical problem of bubbling. We have been looking at this problem for decades. But suddenly a potentially new way of looking at it has emerged. Tritton and Egdell[16] found that bubbling from a submerged orifice is sometimes regular and sometimes irregular. They observed a period-doubling sequence leading to chaotic behaviour. Subsequently, intermittency of varying degrees and period-3 patterns were observed. Examples such as this suggest that such new tools can lead us to look at dispersion science in a very different way.

Consider another classical problem of mixing. Recent experimental studies and the merging of kinematics with dynamical systems and chaos are providing a paradigm for analysing mixing from a universal viewpoint. This is as well, since there is a large spectrum of problems studied in various disciplines in which mixing assumes importance (Figure 1). A universal framework can be used for analysis in different disciplines, whether it is mixing in a screw extruder or mixing in the mantle of the earth[17].

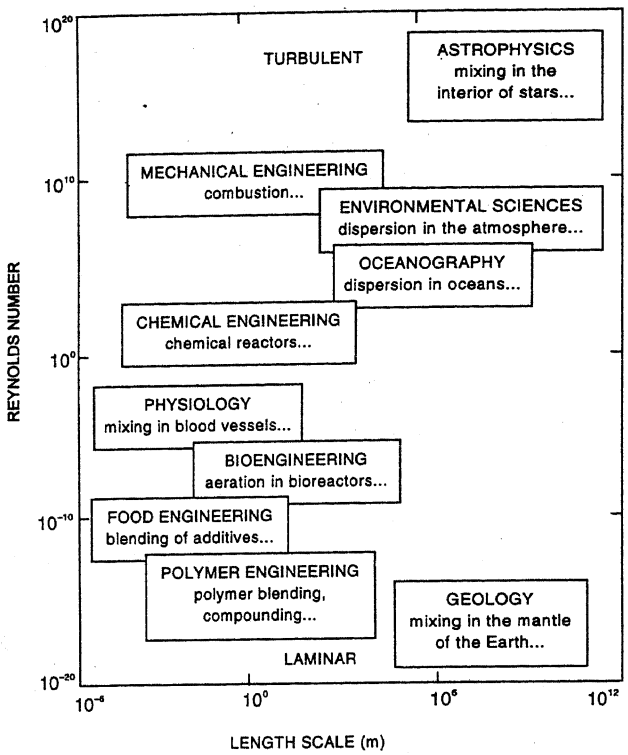

Figure 1. Mixing phenomena studied in diverse disciplines.

The real excitement lies in the potential of achieving laminar mixing of viscous fluids in a regime of deterministic chaos produced by intermittent change of initial conditions[18–21]. Here mixing results from a fundamental kinematic property. In such chaotic processes, mixing efficiency is not directly related to energy dissipation. The prospect of devising entirely new mixing devices based on these new principles is truly exciting. The recent work by Howes *et al.*[22] is interesting from this angle.

The examples I cited are typically those that are at the heart of chemical engineering. But let me move on and tell you about a more complex system, which combines the synergistic efforts from diverse disciplines being interpreted using the theory of chaos, which leads to new ways of taste detection. Let us consider membranes with biological activity. The central question concerns the interrelationship between the microscopic and macroscopic membrane properties. Properties such as the action potential, spontaneous firing and chaotic behaviour can be viewed now from a system-dynamical viewpoint. Thus, for example, the mechanism of oscillatory electrical potential of dioleyl phosphate millipore filter membrane placed between two solutions of different electrolyte concentration can be related to the macroscopic behaviour of interfaces generated due to chemically driven surface tension effects[23]. The system, when subjected to sinusoidal alternating current, synchronizes with the forcing frequency and also desynchronizes for changing initial conditions. Aperiodic behaviour in the form of chaos appears in the regime[24]. The appearance of chaos follows the route of quasiperiodicity and analysis of dynamic chaos enables us to use it as a sensor for detecting taste. The simple philosophy followed here is that the substances as received by biological membranes change the membrane potential, leading to sustained oscillation and spatiotemporal firing patterns of the neurons, which when transmitted to the cortex and the brain recognize the taste. It is thus possible to use an artificial lipid membrane to convert chemical information to electric currents and construct sensors that identify the taste. The prowess of the synergy of diverse disciplines is at once obvious here. A CE scientist should simply relish the idea of exploring, analysing and exploiting analogous phenomena and enriching the profession.

Fractals is another concept that has excited the physics community over the past two decades. Fractals are scale-invariant geometric objects with the property that when a small piece is magnified it resembles the whole object statistically. Many physical processes produce phenomena that show self-similarity over a wide range of scales. The methods of fractal geometry have been extensively used in diverse disciplines, ranging from atmospheric sciences to modelling of earthquakes and also in miniature systems in cell biology. Aspects of fractals in chemical engineering problems that we deal with, be they porous electrodes, catalytic surfaces, membranes and so on, have been dealt with very elegantly by Villermaux[5]. A lack of quantitative connection between the measured value of the fractal dimension and the underlying physics of the process has many times led to a scepticism about its meaningfulness. If one comes out with a fractal dimension after a lot of sweat and hard work, we often have someone saying, 'so what?'. Fractals are not merely physical objects but are strange attractors of the nonlinear systems, which make them all the more beautiful, while being all-pervading at the same time. The connection of physical and mathematical fractals is, however, important, since it links the nonlinear system dynamics to fractal geometry.

The methods of fractal geometry when applied to data obtained from mathematical model, while providing an insight into the behaviour of these nonlinear systems, are grossly inadequate for the measured experimental time series data. Also the presence of noise in the experimental data seriously distorts the results. Clearly, there exists a need for efficient noise reduction methods for dynamically sensitive systems, which need to be tested possibly on model examples first and then on real experimental systems. As more CE scientists get attracted to fractals, these words of caution may be useful.

CE scientist as a molecular information engineer

Molecular chemistry that a chemical engineer conventionally learns is that of a covalent bond. However, it is supramolecular chemistry that is holding the centrestage now. Supramolecular chemistry is the *designed* chemistry of the intermolecular bond[25,26]. It deals with chemical species that are held together and organized by means of intermolecular (noncovalent) binding interactions. The chemical, physical and biological features of these chemical species constitute the essence of this highly interdisciplinary field. It involves the organic synthetic techniques of receptor construction, metal-ion–ligand complexes involving coordination chemistry, studies of interactions involving physical chemistry and finally biological processes involving substrate binding and recognition. Its location at the intersection of chemistry, biology and physics makes it a unique one and it also offers great challenges to a CE scientist.

Designing systems for storing information in the structural (and eventually temporal) features of molecules and supermolecules constitute the real essence of supramolecular science and engineering. Supramolecular science deals with the process of molecular recognition. The essence of molecular recognition is that the molecular information is stored in the interacting partners. Chemical ingenuity is used to design receptors possessing steric and electronic features. These are designed to be complementary to those of the binding substrate. Further molecular manipulation provides a balance between the rigidity and the flexibility suitable for the function to be performed. Such subtle organization of molecular, structural and dynamical features forms the basis of *molecular information engineering*.

Why should a CE scientist get involved with this field? This is because molecular information engineering will be finally concerned with the design of molecular devices and of systems displaying higher forms of molecular and supramolecular behaviour such as self-organization, regulation, cooperativity, communication and replication. Let me explain this a little further.

We know that an interplay between molecular self-organization and molecular recognition of individual constituents leads to the construction of natural supramolecular systems. Such systems combine order and mobility. Their functioning depends on the organization. If CE scientists abandon the limits of their classical thinking, they can start conceiving the development of new materials, which simulate natural supramolecular systems, where their functioning will be governed by their organization. The connecting links between apparently separated disciplines of materials science and life science bringing in the central theme of supramolecular systems is demonstrated in Figure 2.

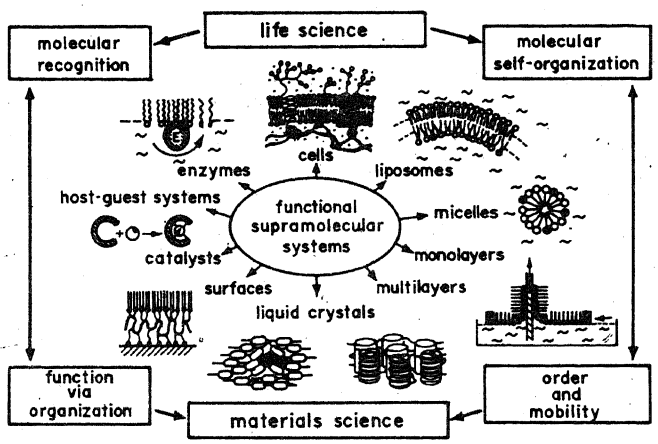

Figure 2. The connecting link between life science and materials science – the role of functional supramolecular systems.

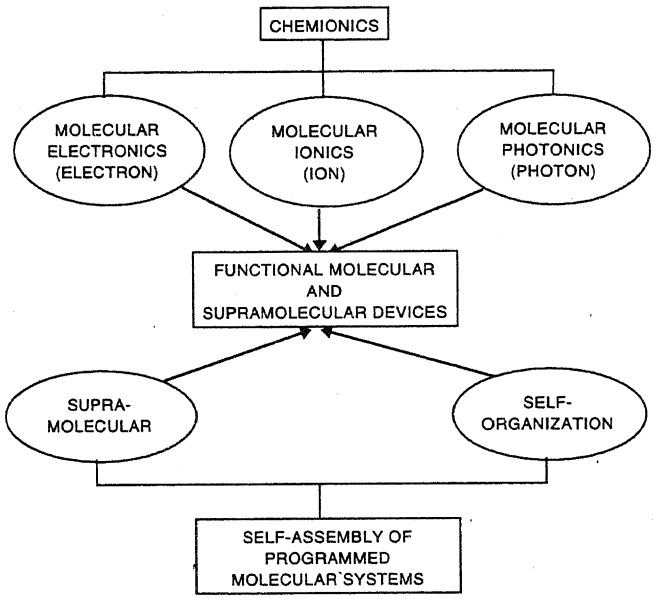

Figure 3. Chemionics as the chemistry of recognition-directed and self-organized photonic, electronic and ionic molecular and supramolecular devices.

But how do we enter this exciting field? The chemistry of molecular signal generation, processing, transfer, conversion and detection is already being hotly pursued by innovative chemists. The job of a molecular information engineer, if I may use that term, will be simply to design, build and operate molecular devices, which will be structurally organized and functionally integrated chemical systems built into supramolecular architectures. The function performed by such molecular devices will be the result of the integration of the elementary acts performed by the components, which may be photoactive, electroactive or ionoactive, depending upon whether they operate with photons, electrons or ions (See Figure 3). Strategies towards properties and

functions rather than towards structures will be the goal of a molecular information engineer. He will continuously seek to express a desired property in a molecule or a material, whatever be the composition and the structure.

What I have said so far sets out the general background. But now let me give a specific example of how CE scientists can use molecular information engineering in polymers to solve some challenging unsolved problems. I focus on the exciting idea of creating molecularly imprinted polymers. Molecular imprinting in polymers involves the idea of using a specific imprinting molecule to coordinate the assembly of synthetic monomers around a molecule of interest. The functional monomers are polymerized in the presence of a print molecule. The functionality in the print molecule interacting with the complementary functionality is found in the monomer units. A cocktail of functionalized monomers is 'prearranged' around the imprint molecule by noncovalent interactions, which could be ionic, hydrophobic, hydrogen bonding, etc. After polymerization, the imprint molecule is removed from the polymer. This leaves a polymer with recognition sites that are complementary to the imprint species with regard to both shape and functionality. This site will constitute an 'induced molecular memory' which will be capable of selectively recognizing the imprint species. The polymer will have a macroporous structure which will allow an imprint molecule diffusion into and out of the polymer matrix.

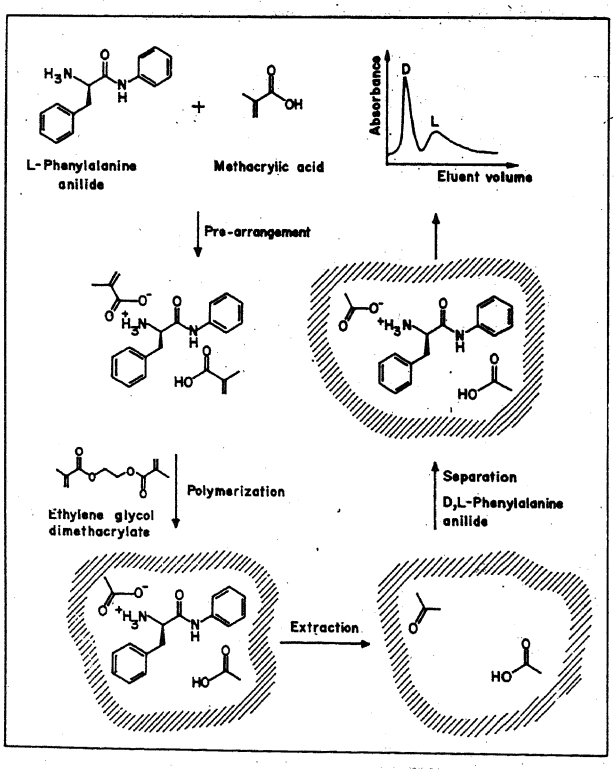

Figure 4. Schematic representation of molecular imprinting by a noncovalent approach of Mosbach[27]. An amino acid derivative is used. Different stages in imprinting technique leading to a molecularly imprinted polymer (MIP) capable of baseline separation of racemic mixtures are shown.

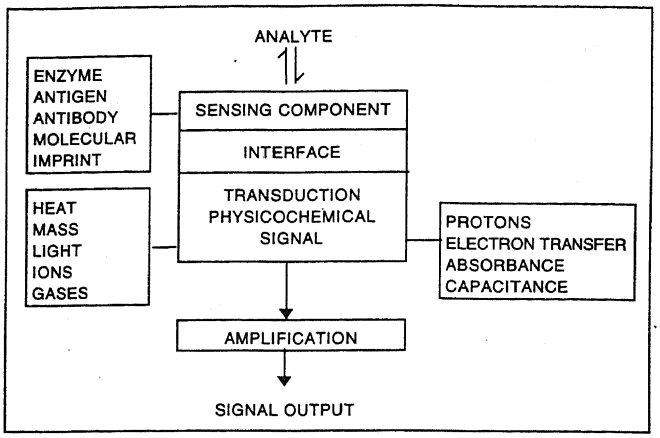

Figure 5. The principles underlying conventional biosensor operations and the possible role of MIPs in their function.

Molecularly imprinted polymers (MIPs) are exciting, since they have a fascinating range of applications. Figure 4 shows a schematic representation of molecular imprinting through a noncovalent approach using an amino acid derivative demonstrated by Mosbach[27]. Here, after mixing the imprint species with functional monomer and crosslinker, polymerization is initiated and the print molecule extracted from the resultant polymer under acidic conditions. Such MIPs find immediate applications in the challenging task of separation of racemic mixtures. Separation factors of between 2 and 8 have been achieved. What is impressive is that the molecular memory of the MIPs is not lost despite their manifold use in racemic resolutions over a period of several months.

This opens up an exciting new field of separation science for us in a challenging area such as chiral separations, where so far traditional chiral stationary phases (CSPs) have been used. Tailor-making binding polymers for a given separation process without involving the 'trial and error approach' inherent with different CSPs will be a big gain if we followed this strategy. The science–business connection is obvious here too. Please remember that of 500 or more optically active drugs presently in the market, about 90% are administered as racemic mixtures. Food and Drugs Administration regulations now require that for any new optically active drug, both enantiomers must be treated as separate substances in pharmacokinetic and toxicological profiling. Molecular imprinting might be the way to permit enantiopolishing, i.e. the removal of small amounts of contaminating optical isomers on a commercial scale. Separation and purification of wide ranges of molecules by exploiting the stereospecificity and regiospecificity

promises enormous potential with applications in differentiation of isoenzymes, conformers or epitopes and so on.

One can extend this molecular information engineering further, since MIPs can also move into substrate-selective polymers as sensory components. The idea will be to substitute the bio part in an enzyme- or antibody-based sensor with catalytically active or ligand-specific polymers prepared from specific polymers imprints. These can then move towards more robust sensing element systems (Figure 5).

In many cases no suitable biomolecule will be available. It is here that molecular imprinting will have the greatest potential. It will be able to create the custom-tailored synthetic binding site for a given molecule. The possibility of 'direct contact' systems, where 'molecular wires' could be created linking the binding cavity directly to a transducer, such as an electrode, to give rise to an instant signal upon binding follow naturally. A whole range of exciting possibilities will open up as soon as the real prowess of molecular information engineering is seen by CE scientists.

CE scientists and living systems

The fascination of chemical engineers for living systems dates back to several years. Whether it is transport phenomena[28] or reaction engineering[29] in living systems, CE scientists have brought elegant tools of sophisticated analysis to this field. Modern biotechnology, be it industrial, medical, environmental or some other, has always put a great demand on truly borderless behaviour between diverse disciplines. For instance, medical biotechnology thrived only because of a close cooperation between biologists, biochemists, geneticists, immunologists, medical specialists, chemical engineers and so on. Challenges of implantable and extracorporeal devices that duplicate the function of mammalian organs or facilitate the prevention or treatment of diseases are being met only through borderless laboratories combining several disciplines. Metabolic engineering and tissue engineering, in which CE scientists have got involved, require strong interdisciplinary teams. Search of novel biocompatible materials for prosthetic replacement and repair of both hard and soft mammalian tissue is also showing promising results only due to such synergy of action. Unresolved problems in industrial biotechnology of development of highly accurate, sensitive, and selective sensing devices capable of measuring concentrations of bioactive substances and metabolic components in bioprocess streams and monitoring these parameters for computer control also require strong interdisciplinary teams.

What chemical engineers have already achieved is something to be proud of. Significant contributions have been made in industrial biotransformation processes[30], the subject of last year's Danckwerts memorial lecture. Chemical engineers had the lion's share in the development of artificial kidney, pursued initially as a natural extension of their work on membranes. They were at the centrestage when insulin was produced on a large scale using recombinant DNA technique. Now they have moved a step further by developing hybrid pancreas. The idea is to take live pancreas cells and immobilize them in an inert matrix to be used as hybrid pancreas. In drug delivery systems, we are now talking of low flow pumps and smart membranes. In low flow pumps, microcapsules are so produced that each releases its contents at a specified time. Smart membranes will sense the glucose level of the blood and release the required amount of insulin. Attempts are even being made to generate artificial red blood cells, which will not contain any living matter and yet perform the functions of the cells in great detail.

In this context it is worth quoting from an editorial that was written by Frauenfelder and Berg[31] in connection with a special issue of *Physics Today* that dealt exclusively with the emerging new relations between physics and biology. They said 'interface between physics and biology ... is a cross-field endeavour to which physicists can make major contributions. But to do so, they need to learn enough biology to be able to talk with biologists and to distinguish problems that are central from those that are peripheral. Since much of biology is descriptive, the physicist has a strong advantage: It is much easier for a physicist to learn biology than for a biologist to learn physics'.

Just replace the word 'physicist' with 'CE scientist' and read the above paragraph again. The idea is clear. CE scientists have already played a crucial role in bringing quantitation to biology[32]. The tools and skills that we will use in future will also come from diverse disciplines again. My chemical engineering colleague in NCL, Bhaskar Kulkarni, recently wrote a paper[33] on the application of artificial neural networks for procaryotic transcription terminator predictor and it featured on the front cover of the journal *FEBS Letters*. The interesting point here is that a chemical engineer has picked up a tool developed by electrical engineers and mathematicians and contributed to quantitation of a biological problem!

CE scientists are making headway in developing more advanced methods. The growth of procaryotic cells has been predicted in a rigorous quantitative way – a far cry from our gross Monod and Michaelis–Menten equations. Such new models consider the formation of proteins from amino acids, RNA as well as DNA from nucleotides and cell wall membranes from lipids, not only for the parent cell but also for the plasmids contained in it. The distribution of plasmids as the cells multiply has also been predicted.

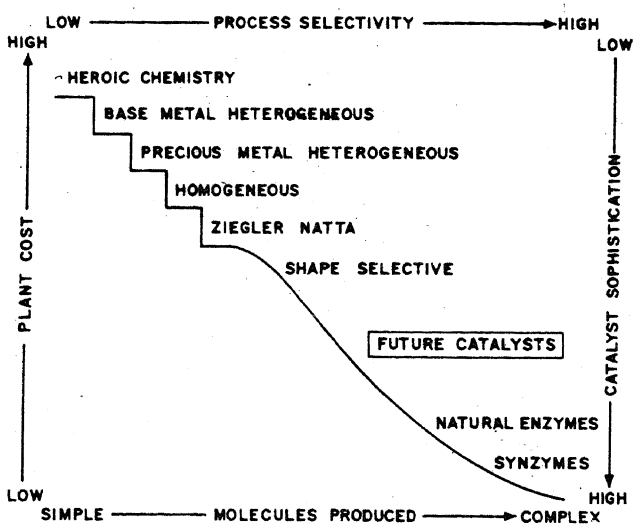

Figure 6. Historical trends in the development of catalysts.

Let us, for a moment, look at enzymes, which the CE community is looking at as catalysts of the future. Figure 6 shows the way in which catalyst development has moved over the years. The chemical engineers have so far contributed to the development of production processes of commercial enzymes. They have tried to immobilize them and so on. However, once again if they become borderless then they can get involved in an even more exciting game, namely displacing the enzymes themselves. Indeed, designing catalysts functioning in a manner similar to natural enzymes, i.e. creating synzymes, is emerging as an exciting challenge, as we can see from Figure 6.

Enzyme catalysis involves binding of the reacting substrate in a perfectly fitting cavity or cleft of the enzyme that contains functional groups in the correct stereochemistry for binding, catalysis, and group transfer. The idea of using zeolites as hosts has opened up the field of zeozymes. Use of molecularly imprinted polymers now offers interesting possibility for creating enzyme-like catalysts too. But as we become more and more borderless, we can start bringing in diverse ideas from different disciplines. A recent breakthrough[34] is worth describing.

Many attempts have so far been made to create a synzyme for the purpose of catalytic oxidation on lines of the enzyme cytochrome P-450. Heterogeneous mimics have been designed that use organometallic complexes encapsulated in the supercages of zeolites, which are the so-called zeozymes. However, these systems have no real mechanistic analogy with the enzymatic process, and the oxidation rates tend to be low. Parton *et al.*[34] tackled this problem by developing a composite

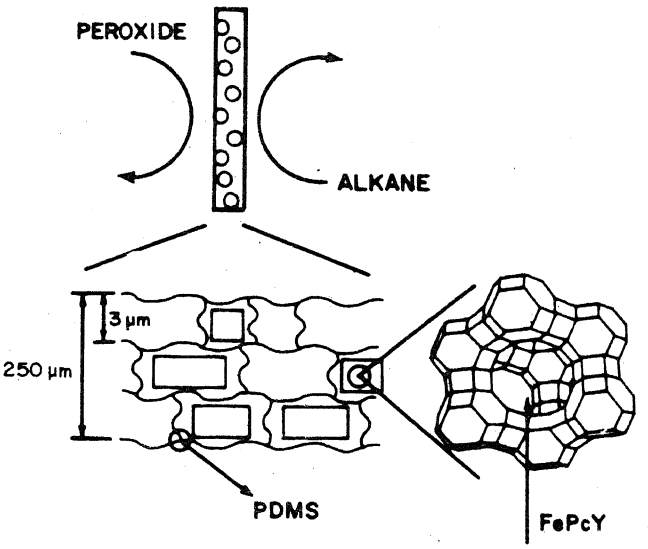

Figure 7. Zeozyme in a polymer membrane providing a mimic of cytochrome P-450.

catalytic system by incorporating iron phthalocyanine complexes encapsulated in crystals of zeolite Y, which were in turn embedded in a polydimethylsiloxane membrane (Figure 7). The polymer served three purposes. It acted as a mimic of the phospholipid membrane in which cytochrome P-450 resides. It acted as an interface between the two immiscible phases. It avoided the need for solvents or phase transfer agents. The system oxidized alkanes at room temperature and showed amazing turnover. The premium here again was on creativity, daring and combining concepts from diverse disciplines in an uninhibited fashion!

The way the field will move will be hard to predict by any logical and structural analysis. We already have examples of animals as bioreactors – take the case of transgenic cows producing human lactoferrin or transgenic sheep producing α-1 antitrypsin. Modern biotechnology is thus helping us to replace bioreactors by animals. On the other hand, modern polymer science is helping us replace animals by plastics! Let me explain this.

Immunoassay techniques require antibodies produced from laboratory animals. How about making plastic antibodies? This is not a dream anymore. All that we need is an exploitation of molecular information engineering done on chosen polymers so that they will become antibody mimics which will be comparable to biological

antibodies. It has been shown[35] that molecularly imprinted polymers could be made which show strong binding and cross-relativity profiles very similar to antibodies. Now this opens up an enormous opportunity, since MIPs can be made against a great number of organic molecules, for example, drugs, metabolites, hormones and toxins, provided they have suitable interaction points. It is easy to see then the amazing synergistic effect of diverse disciplines merging together.

CES and nanotechnology

Great expectations on nanosystems (1–100 nm) have been raised recently. Exciting pictures of nanoscopic machines that replicate, build crystalline rocket engines, repair cells and extend life spans have been painted[36,37] and even new strategies of doing all this by micromachining have been suggested. However, there is a problem here, since such nanomachines must themselves be put together by other nanomachines! Ideas of building molecules by pushing together atoms by the tip of the scanning tunnelling microscope have also been suggested. We can only imagine how slow and cumbersome these processes will be. Solid-state physicists, materials scientists, and electrical engineers build nanostructures through techniques such as chemical vapour deposition, etc. However, fabrication of microstructures and devices requires increasingly substantial effort as they are extended to the range below 100 nm. Then how can we proceed?

While we are all struggling, biology abounds in nanostructures with dimensions of about 1–100 nm (ref. 38). Just consider the range of biological structures – from proteins to viruses to cellular organelles. The challenge is to make structures of the size and complexity of biological structures, but without using biological catalysts or the information coded in genes. Nanotechnology, therefore, requires new strategies and technologies.

Self-assembly is emerging as a new strategy in chemical synthesis, with the potential of generating nonbiological structures with dimensions of 1–100 nm. Structures in the upper part of this range of sizes are presently inaccessible through the chemical synthesis route and the ability to prepare them would open a route to structures comparable in size (and perhaps complementary in function) to those that can be prepared by microlithography and other techniques of microfabrication.

What can CE scientists do here? One option is to look at the nature and see how we can exploit the self-organized structures that it has already created. The second is to understand the process of self-organization and simulate it synthetically to create new structures. Both approaches require ingenuity but both are possible, as I will show.

Surface layers (S-layers) represent the outermost cell wall component of many eubacteria and archaebacteria. These S-layers are arrays of protein or glycoprotein subunits that are linked by noncovalent interactions. Channels of 2–6 nm diameter exist in S-layer lattices. This beautiful S-layer material was isolated from highly thermophilic eubacteria, crosslinked with glutaraldehyde and then it was deposited on commercially available microfiltration membranes[39]. The only function of the microfiltration membrane was to provide mechanical support. These membranes displayed unusually steep rejection curves. Such new types of UF membranes will have considerable potential in opening up new doors to ultrafiltration technology.

Let us now turn to synthetic methodologies. Block copolymers have particularly interesting features with respect to equilibrium statistical mechanics, forming various phase-separated domain structures with nanometer periodicities, the so-called nanopatterns. Recently, a breakthrough was achieved[40] in using the process of self-organization in block copolymers of polystyrene–polyparaphenylene. The films, of 10–30 μm thickness, were produced by evaporating solutions in carbon disulphide under the flow of a moist gas. Empty spherical cells about 0.2–10 μm in diameter appeared spontaneously in a beautiful hexagonal array. Such membranes might find application in controlled release of drugs or other bioactive species, or as materials with useful optical properties, moulds or scaffolding for forming ordered microstructures, and model substrates for surface science. What is remarkable is that the polymer architecture is able to induce a complex regular morphology at a scale two or three orders larger than the molecular scale. The mechanism of formation of this new regular morphology involves a combination of complicated thermodynamics and transport phenomena and provides an interesting challenge to CE scientists.

Nanobiotechnology is emerging as an exciting field. Fabricating organized biomolecular structures is a new challenge that is being met by bringing in diverse disciplines. Genetic engineering will tailor protein's makeup and also its function. Organic chemistry will provide new materials for anchoring and preserving the altered proteins. Electrical engineering will offer ways to detect signals from internal working of proteins. We can finally turn a small assembly of biomolecules into a custom-designed molecular machine.

Another exciting area is where proteins are being turned into nanoscale chemical processing plants. Proteins can be used as reaction vessels for controlling the particle size of other materials. They can cage several compounds. If the chemical affinity of the protein can be changed, then the protein can be engineered to fit the mineralization product that one wants inside it. Such

caged particles will pass through the human body in an unrestricted way. They will be useful in diagnosing and treating diseases. It is clear that CE scientists can share the grand challenges of nanotechnology by joining hands with others working in protein engineering, organometallic chemistry, semiconductor technology, etc.

Entering new territories

Venturing into new fields will be both exciting and rewarding for CE scientists. Nontraditional thinking, whether it is in terms of creative use of ultrasound, photoenergy, microwaves or some other means, will continuously give the CE scientists new challenges and new opportunities. Laboratory curiosities or chance observations in other disciplines can be turned into major opportunities with winning technologies if we are both vigilant in watching other fields and daring. Let me take one specific example in detail, namely sonochemical reaction engineering.

Chemists have shown over the years that application of ultrasound yields entirely different products from the same reactants, enhances the rates of the reactions phenomenally and even permits at very mild reaction conditions synthesis of products that can normally be done only under very high temperatures. Although catalogues of the use of ultrasound by chemists are available[41], little or no work aimed at quantitative prediction of the effects of ultrasound on the course of chemical reactions has been carried out. Now sonochemical reaction engineering is beginning to emerge as an exciting area of research for CE scientists, since it combines so many novel elements of cavitation dynamics, transport phenomena and reaction engineering.

The influence of ultrasound on chemical reactions is known to come from the cavitation phenomena. Very small bubbles of dissolved gases that are omnipresent in the liquid can grow in the rarefaction cycle of the sound wave and collapse rapidly and adiabatically during the compression cycle. The adiabatic compression generates very high temperatures and pressures in the bubble. Reactive intermediates are then born, which can diffuse out and react with other reactants present in the surrounding liquid phase. Further, when a cavitating bubble collapses near a solid surface, it does so asymmetrically and generates microjets of high velocity. The resulting microjets can clean the solid surfaces. Such a cleaning action leads to reactivation of passivated catalytic surfaces and also local heating of catalytic surfaces. This results in impressive enhancement of the rates of reaction. The high velocities generated can also decrease any diffusional resistance present and, once again, enhance the rates of the reactions.

The big question is how can sonochemistry be taken through the path of sonochemical reaction engineering to sonochemical technology? A body of engineering knowledge has still to be acquired before design of reactors or even scale-up can be achieved. The first paper on sonochemical reaction engineering, which provides a high level of predictive ability, appeared a few months ago[42]. It is interesting to see that a multidisciplinary team of chemical engineers, mechanical engineers and chemists worked together to provide insights into the fluid-dynamical phenomena as well as the reaction events.

A lot more needs to be done in sonochemical reaction engineering. Capturing the dynamics of a cavitating bubble, postulating the rates of reactions occurring in the bubble that produce reactive intermediates, modelling of convection created by microjets and acoustic streaming, investigation of pitting and its effects on creation of new surfaces, understanding the physics of the fusion of particles and the new catalytic chemistry are some of the interesting challenges in modelling. But an even bigger challenge is to make a sonochemical reactor work in practice. New ideas on loop reactors are emerging[43]. Normal sonicators have the problem of erosion of the power-transmitting surfaces due to cavitation. How do we concentrate the power away from the transducer surfaces? The use of spherical vessels for batch reactors or hollow cylindrical-type transducers to position the power around the centre of the axis seems to be a possibility. However, only a close interaction with acoustic engineers, mechanical engineers, chemists, etc., can move this field further.

The use of ultrasound is just one possibility. Interesting opportunities exist for the development of applications of both electrochemistry and photochemistry. Unusual cross-disciplinary thinking is needed though. The concept of using electrical potentials impressed upon metallic or semiconductor catalysts to bias either the rate or pathway of a heterogeneous catalytic reaction to affect the reaction kinetics or product distribution is an unexplored area. Can we carry out electrochemical (i.e. electron insertion/withdrawal) processes at electrode surfaces in the proximity of immobilized enzyme systems as a means of conducting oxidative or reductive enzymatic transformations? This will do away with the necessity of cofactor reactants. Another interesting challenge is the simultaneous generation of electric power with production of useful organic intermediates by controlled catalytic oxidation or reduction at an electrochemical cell electrode. Such 'bootstrap' chemical processes, which are energy- and raw-materials-conserving, will make the profession leap-frog.

If we go really borderless, then we can think in terms of the combined-fields approach[44]. We can generate additional driving forces in a process that works simultaneously with the conventional driving force of the process. The additional forces may evolve from the application of external fields or body forces. Electric

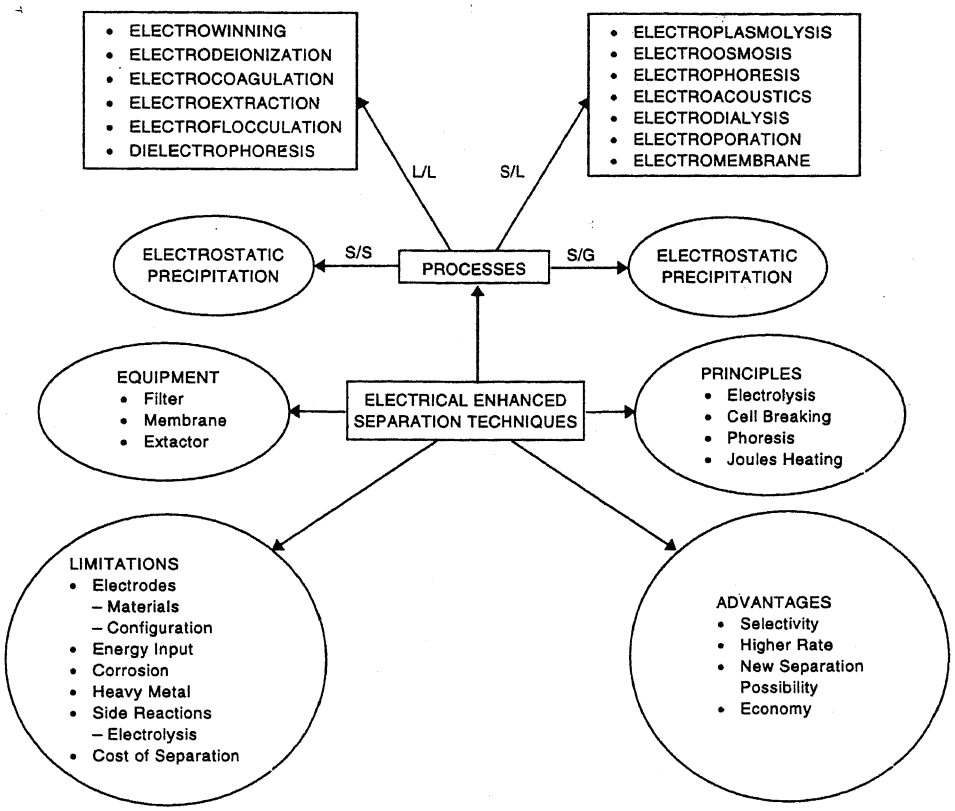

Figure 8. Range of electrical enhanced-separation techniques.

field, which is one possibility, has already been explored for enhanced-separation techniques (Figure 8), but my feeling is that we have only been scraping the surface so far and a lot of unconventional thinking has to go on here.

Take, for instance, an imaginative use of the electrical field in the pulsing mode. We know[45] that an electric pulse of intensity in kilovolts per centimeter and of duration in microseconds to milliseconds can cause a temporary loss of the semipermeability of cell membranes, thus leading to ion leakage, escape of metabolites, and increased uptake of drugs, molecular probes and DNA by cells. This phenomenon is referred to as 'electroporation'. Electroporation can find applications in insertion of proteins into cell membranes, improving drug delivery and hence effectiveness in chemotherapy of cancerous cells, activation of membrane transporters and enzymes, etc. Why not design very cheap disinfection or water purification processes based on electroporation?

Let us pursue the idea of pulsing and look at other possibilities. Consider membrane fouling during cross-flow microfiltration. We can imaginatively use electrolytic membrane cleaning. Here again, intermittent electric field pulses can be used to clean membranes without the interruption of the separation process. It has already been shown[46] that this technique can improve the overall membrane permeation rates by a factor of up to 10 with only a modest electrical energy requirement. Another technique, namely the *in situ* electrolytic membrane restoration, is very effective in restoring membrane water permeation rates under mild chemical conditions. Used in combination, these techniques have the potential of obviating the requirement of membrane backflushing and conventional chemical cleaning.

Let me emphasize again that these examples are by no means exhaustive but are only typical of the opportunities that exist. Photochemical and electrochemical reaction engineering have already matured. Sonochemical and microwave reaction engineering are emerging as new disciplines. Asimov's orbital reaction engineering[47] may be a long way away – but emergence of other fields will depend on our creativity and daring again.

New look at old materials through seamless science

With rapid advances in science, a CE scientist will have an opportunity to look at old materials and make them perform new functions. He may even convert them into smart materials with attributes of selectivity, sensitivity, shapability, self-recovery, self-repair, self-diagnosis, self-tuning and switchability. Use of some severe interdisciplinary science is required here to make this happen. For instance, 'dumb' water-swollen gels, which are

just used as passive supports, can be so transformed that they bend, walk and even mimic enzymes! To show such an exciting range of possibilities, I will just choose three familiar materials, namely gels, zeolites and clays.

Let me focus on gels first. Biological materials in the body are usually composed of soft and wet materials. This is in contrast with most industrial materials that we chemical engineers use. Take, for instance, metals, ceramics and plastics. These are dry and hard. Seldom do we use soft materials. But it is beginning to emerge now that 'soft and wet' materials can be important not only as biological materials that construct the body but also for displaying their functions. Designing mobile machines using soft and wet materials, furnishing soft materials so that they are able to make shape changes, or to generate tensile stresses that can lead to motility without the requirement of a rigid structure are challenges that will be met in the new world of seamless science.

Let me discuss more specifically polymeric gels, which are swollen polymeric networks. They possess the cohesive properties of solids and the diffusive transport properties of liquids. The combination of elastic properties and osmotic reactivity makes them very special. Gels are held in place by a hydrophilic lattice of long-chain molecules. The fragile balance between the electrostatic repulsion of the adjacent polymer strands and the osmotic pressure exerted by the ions in the solvent holds the key to the behaviour of gels. Disrupting a gel's charge distribution by altering its environment can trigger it to swell or shrink suddenly[48,49]. Such phase transitions can be exploited imaginatively.

The thermodynamics of phase transitions, aspects of transport phenomena as well as the energy conversion phenomena in these gels will be best understood by CE scientists. Indeed, the entry of CE scientists in this area is giving rise to the development of several systems of interest, including separation technology[50,51], sustained release systems[52] and so on.

It is rather interesting to notice the simultaneous generation of ideas in such fields that take place between different disciplines driving different applications using similar principles. Our research group recently used the pH sensitivity of the hydrogels for attaining time-invariant diffusional flux through bilayered membranes with collapsible barriers[52]. The novelty of the approach was that the bilayers were formed *in situ* and the diffusional behaviour was manipulated at will depending on the external stimuli. The idea rested, however, on making both surfaces of a gel slab collapsible. Our Japanese friends[53] decided that they would collapse only one of the surfaces of the gel. Their idea was to create a bending motion (Figure 9). By exploiting this asymmetric collapse with the help of a rachet-type 'gel looper', they showed that a gel could 'walk' along a bar! As chemical engineers, it is easy to see that we were interested in controlling diffusion and the Japanese were interested in soft robots – but the phenomena exploited by us were exactly the same.

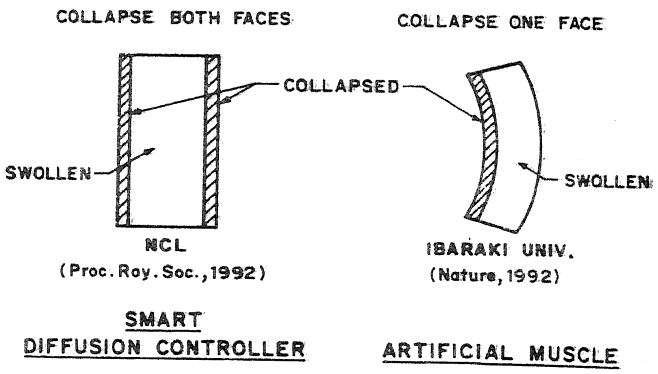

Figure 9. Schematic presentation of two applications of a reversible collapse of a gel bar surface used for designing a smart diffusion controller[52] and a mimic of artificial muscle[53].

In contrast to motors and hydrodynamic pumps, the motion of a polymeric gel demonstrated by Osada *et al.*[53] is produced by the chemical free energy of the polymer network. Thereafter, electrical or thermal energy is used to drive the direction and control the state of the equilibrium. Thus, the chemomechanical gel driven by outside stimulus is able to exhibit 'gentle' and 'flexible' action, and its movement is more akin to that observed in a muscle than in the metallic machine systems. The application of chemomechanical gel as an 'actuator' for robots and other systems has special interest. The molecular machine that is capable of biomimetic motility by using gel will allow entry into a new world of movement where the system works smoothly and gently without noise, heat evolution and exhaustion[48, 54]. Applications might eventually include the construction of devices that can be inserted into muscle and even emulate the nervous system. This field opens up so many new exciting vistas for CE scientists.

Let us now move to zeolites, which were initially discovered as naturally occurring materials. Much zeolite research and development with which chemical engineering scientists are associated is still aimed at the traditional uses such as catalysts and adsorbents. However, over the past few years we have seen zeolites emerge as advanced materials[55]. Indeed, zeolites as microporous materials with nanometer dimension window, channel and cavity architecture present new opportunities. The key in assembling and maintaining controlled microstructure is to use solid host lattices that serve as templates within which a guest structure of nanometer architecture can be assembled. This opens up new possibilities.

Take the field of solar energy conversion. Here a spatially well-organized molecular system is required that models photosynthetic mechanisms. This will enable

redox reactions to proceed efficiently along the desired paths. Other potential applications include zeolite electrodes and electron relays, zeolite batteries, zeolite fast-ion conductors, intrazeolite semiconductors, zeolite chemical sensors, zeolite imaging and data storage materials, zeolite lasers and displays, as well as zeolite composites to form perm-selective membranes or thin films.

The stage is set for rapid developments of zeolite-based electronic, optical, magnetic and dielectric materials. Zeolite semiconductors may not be far away. The marked proton conductivity of certain acid zeolites may open up the ways to electrochromic zeolites. The emergence of acentric zeolites may lead to the design of zeolite piezoelectric devices. The molecule-sized pore and channel structure of zeolites could provide a novel medium in which to create ultrahigh resolution images and package and process information at high storage densities. The unidimensional channel architecture of certain zeolites may even permit the assembly of low-dimensional zeolite conductors and the control of energy transfer and energy migration in restricted dimensions. How do we overcome the present disadvantages of zeolites, namely pore plugging, poisoning, structural defects, the difficulties of growing large single crystals, and interfacing a zeolite device with the outside world? A CE scientist is well poised to take upon himself some of these challenges. But he must operate in the borderless way interacting with materials scientists, physicists, electronic engineers and so on.

Let us look at another old material that we are so familiar with – namely, clays. There have been suggestions that clays may have served as templates for the first self-replicating systems on this planet[56]. Indeed, clays have been considered as possible chemical microreactors in the prebiotic synthesis. They may very well have served as 'low-tech' precursors to the self-replicating biomolecules. Oligomers of glycine have been formed in the presence of clays subjected to cycles of wetting and drying simulating natural cycles. It has been demonstrated that energy due to mechanical stress could be stored within the lattice as trapped holes, and released in the form of additional acidic catalytic sites. Luminescence can be induced by dehydration of a clay and mechanical stress can translate into triboluminescence. In short, clays can store energy from the environment and release it in various forms.

Is it not then possible to let our imagination run wild and aggressively move into this area? We can raise a number of questions. Can clays oligomerize simple molecules into biomolecules? Can the required dehydration reactions occur in an aqueous environment? Can clays protect their reaction products from photodecomposition under intense irradiation from sunlight? Can clays store energy and release it by transforming it into chemical energy to operate these condensation reactions? Can clays distinguish stereoisomers to form certain products selectively? The answers to most of these questions are positive. Can the CE scientist not move aggressively to exploit these materials?

What I have tried to emphasize here is that innovation is the key to making mundane materials smart or adding enormous value to them. However, the innovation will emerge only if we intermesh intimately with other adjacent sciences.

Acquiring new tools from other disciplines

We must empower a CE scientist with sophisticated tools, both experimental and computational, for him to march ahead. The quest of a CE scientist to probe molecular-level events and structure on the one hand and to gain access to the spatially resolved macroscopic processes on the other will mean that he will be in constant search of new tools. Especially valuable are those tools which allow the measurement of the dynamics of the events (say during mixing) or allow *in situ* measurements during say a reaction–diffusion event on a working catalyst. Once again these tools will be available elsewhere and the real ingenuity will lie in locating them and using them. Thus, tomography technologies are extensively used in medical diagnostics. A thermal neutron-based Computerized Tomography (CT) system may be used conventionally for industrial diagnostics. It is up to the CE scientist to know the relevance and the worth of these tools and bring them into the profession.

If we look around, we see that NMR spectroscopy and imaging, tomography, trajectography, image processing capability, etc., are serving as powerful aids for CE scientists, who are searching for more and more detailed information. Let us see how this is being achieved by taking a few specific examples.

Tomography techniques used in the medical field cover a wide range of tomographic sensing techniques. These include nucleonic (X-ray, γ-rays), optical, ultrasonic and electrical methods. Some of these methods would have limitations for CE problems at hand. For instance, optical sensors are not useful in opaque systems. Radiation-based sensors are slow, expensive and have safety constraints. However, the scope for the use of these techniques is enormous. Electrical capacitance tomography can be used for nonconducting systems. Electrical resistance tomography can be used for conducting systems. Optical tomography has already been used for imaging mixing process within agitated vessels.

An eye for application of new tools will take us a long way. For instance, consider positron emission tomography (PET), an imaging technique widely developed for diagnostic medicine. It was imaginatively applied by chemical engineers to examine the problems of mixing of powders and gain some valuable new insights[57,58].

Similarly consider a commonly used technique in industrial diagnostics, namely thermal-neutron-based CT system. It can be operated in a radiograph mode to obtain 2-D transmission images or in the real-time mode to image dynamic events. Both systems can be used in conjunction with computerized tomography for 3-D imaging. Jasti and Fogler[59] used this technique imaginatively recently in getting some important insights into porous media flow.

Let us cite a specific example to illustrate the power of these techniques. Williams *et al.*[60] exploited electrical impedance tomography to study mixing in stirred vessels. The batch mixing of a slug of brine tracer was mapped out. Simultaneous capture of video images of the tracer mixing provided a visual confirmation of the tomography reconstruction. The experimental acquisition of fully 3-D concentration field information was particularly satisfying. Such work provides a powerful incentive to develop and implement fully 3-D models of the flow and mixing, since the details available now are precisely commensurate with the details that are capable of being provided by computational fluid dynamic (CFD) models.

CE scientists getting involved in such endeavours must not be just at the periphery but must also get involved in obtaining deeper insights into image reconstruction problems connected with spatial nonlinearities and also the utilization of 3-D data. Furthermore, after a while, it is also important that they move from the 'comfort zone' of studying 'clean model systems' to 'real-life systems' with these powerful tools. The idea is to solve the 'problems that need to be solved' rather than those that 'can be solved'.

Let us move on to NMR techniques now. Excellent reviews by Gladden[61,62] show the great power of this tool in chemical engineering. NMR probes physical and chemical phenomena occurring over a vast range of both length and time scales. While NMR spectroscopy yields information on structure and dynamics at the molecular level, NMR imaging probes macroscopic phenomena such as structural heterogeneities within materials, filtration processes, concentration and velocity profiles, etc. Such studies enable additional insights into the physics of the problems and may even suggest new strategies.

We ourselves have used NMR extensively over the past few years and found it to be a very versatile tool – for probing both microscopic as well as macroscopic events that take place during the swelling and dissolution of polymers[63–65] as well as during the hydration of superabsorbing polymers[66–68]. Let me just illustrate the point by giving an example. We looked at the molecular-level events while studying the dynamics of mobilization in swelling-dissolving polymers. We saw strange plateau appears in the averaged molecular mobility vs. time curves (Figure 10 *a*) as well as in fraction of

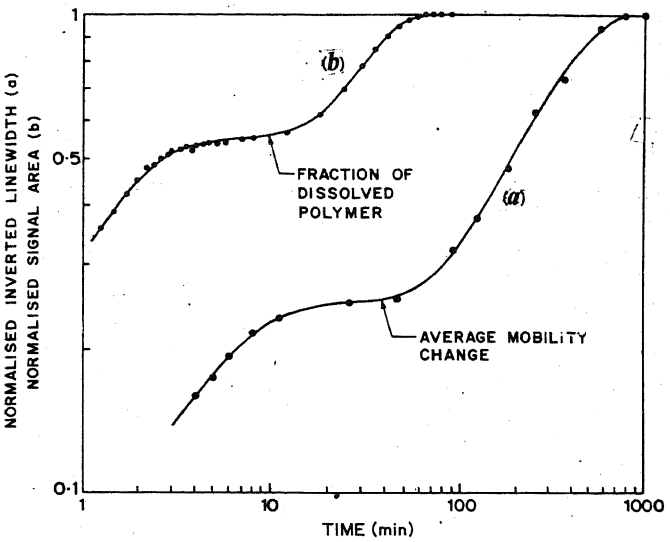

Figure 10. *a*, Reciprocal olefinic proton line width reflects on the average mobility in a swelling–dissolving polyisoprene polymer. The non-monotonous increase of mobility with time is striking[65]. *b*, Normalized signal area measured during dissolution of high molecular weight polystyrene reflects on the dissolved fraction of polystyrene in $CDCl_3$ solvent. The plateau is striking and is influenced by disengagement dynamics[64].

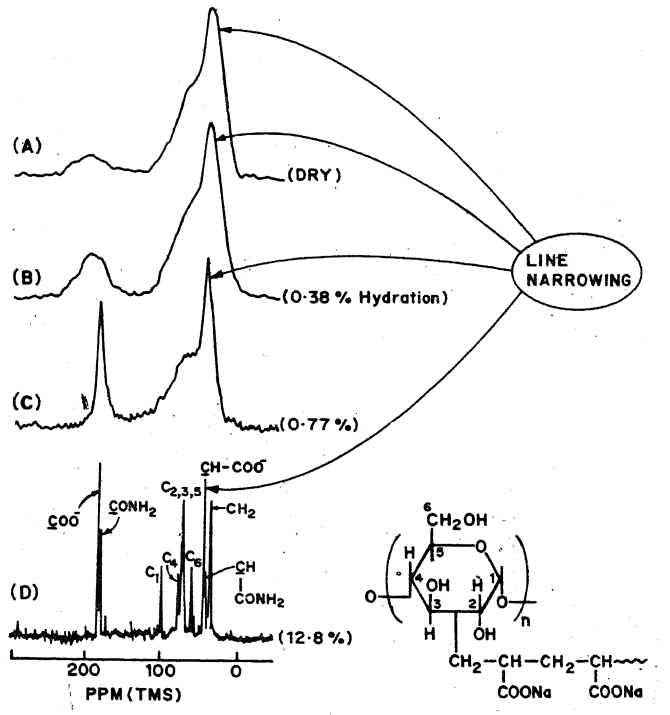

Figure 11. Specific hydration of a superabsorbing polymer (with the structure shown) studied by high-resolution solid-state NMR by Rajamohan *et al.*[68]. Line narrowing at the carboxyl shows preferential hydration at that site despite other hydrophilic groups present in the polymer.

polymer dissolved vs. time curves (Figure 10 *b*). These unexpected observations helped us understand the role of disengagement dynamics at the gel–fluid interface for the first time. We have even been able to examine specific hydration sites in superabsorbing polymers (Figure 11), showing how water mobilizes the carboxyls preferentially, first in preference to other hydrophilic groups. Thus, NMR is a powerful tool that gives important insights into both macroscopic and microscopic phenomena.

In the above example, although we studied molecular mobility of macromolecules, it was still averaged over the sample dimension. However, some recent spectacular advances enable us to observe the dynamic events of reptation of a macromolecule even at a single-molecule level.

Perkins *et al.*[69] observed the tube-like motion of a single flexible DNA molecule by using fluorescence microscopy. Kas *et al.*[70] reported direct observation of reptation obtained by video microscopy of fluorescent labelled filaments of actin in a solution. How such improved understanding of molecular processes of migration and reorientation of DNA molecules undergoing conventional and pulsed field gel electrophoresis, as obtained by direct observations from a microscope and computer modelling studies, has helped in improving these sophisticated separation processes has been shown by Bustamante *et al.*[71]. Advent of such studies at molecular level will empower CE scientists to examine problems of interest to them with even greater rigour.

Let us move from experimental tools to computing tools. CE scientists have not been found wanting in moving quickly and exploiting new advances, be they in artificial intelligence (AI) techniques or in parallel processing, or in some other areas. They have not caught on to virtual reality as yet, but I am sure they ought to – and they will indeed do it soon.

A recent AI application in chemical engineering is the use of artificial neural network (ANN). ANN is a numerical (not symbolic), empirical modelling tool that has received much attention recently[72]. The ANN developments began with computer modelling of the human brain with a view to emulate neuron interactions. The universal approximation characteristic of ANN makes them extremely useful for applications such as on-line fault diagnosis, process control, process modelling, process and product design, trend analysis, etc. The ground is now ripe for wide-ranging applications. The ability to adapt, learn from noisy, incomplete or inconsistent data, better filtering capacity and true multiple-input–multiple-output nature make them indispensable in modern times. In most situations in real-world applications, a chemical engineer would neither have a formal model nor complete experimental data and ANN can help him greatly. Besides serving as a numerical modelling tool in intelligent process manipulations, when combined with symbolic information processing, ANN supports the expert systems and the combination holds very significant technological promise.

Uncertainties abound human endeavours and associated information and data are often vague. Conventional techniques are, therefore, less useful when it comes to modelling and newer tools such as ANN provide some hope. The theory of chaos has already pointed out that apparently random behaviour may, in fact, be deterministic. The notion of fuzziness that prevails has prompted the development of fuzzy models and tools based on fuzzy set theory and logic, and applications in engineering such as reliability modelling, critical-path optimization and fuzzy logic controls are gaining ground. Future developments will, therefore, be clearly dominated by these new emerging tools.

Seeking solutions through new seamless science

Chemical engineers are expected to solve problems. Sometimes one finds a tendency to skirt around these and try and model them. Consider the problem of fouling in polymer membrane devices. Endless number of papers have modelled this phenomenon. But just modelling fouling is being a 'part of a problem' and not a 'part of a solution'. We really need to think creatively of ways and means by which fouling can be prevented. The solutions may require again the use of most severe interdisciplinary science. For instance, now that we know how to use molecular information engineering, why not develop a membrane with a molecularly imprinted polymer? May be a smart self-cleaning surface using 2-D imprint with an attribute of an enzyme mimic might do the trick! Or why not use a piezoelectric polymer which enables generation of mild turbulence at the membrane surface for a continuous cleaning action? However, such solutions require CE scientists with borderless attitude, who will go beyond the traditional thinking and seek solutions from other fields, and this is the new generation of CE scientists we will have to create.

Let me speak from a personal experience on drag reduction. Over 2000 papers have appeared on drag reduction under turbulent-flow conditions in polymer solutions. But these papers have not helped us in resolving the issue of the basic limitation of these polymers, which arises due to their poor shear stability in turbulent fields. Many of us in the chemical engineering community have continued to model the degradation phenomenon. This modelling started in the seventies and continues even today in the nineties[73]. But have we solved the basic problem of *generating* shear-stable drag-reducing polymers? The only way we can solve the problem is by moving from the quest of 'new analysis' to new 'synthesis'. This new synthesis has to be again

based on an understanding of the molecular behaviour of these polymers under turbulent conditions, appreciation of the mechanochemistry of degradation and then finally designing some new synthetic strategies by using good contemporary chemistry.

We recently tried to make a modest effort towards this and achieved at least partial success. We used the knowledge of polymer chain breakage developed by polymer physicists[74]. Then we performed the mechanistic analysis of a perfectly 'zipped' assembly of a fully extended bead rod chain model of macromolecules in an elongational flow[75]. We showed that the enhanced stability of such zipped structures was a result of the distribution (near the chain centre) of the drag tension into the two parallel 'zipped' chains and reduction of the drag force due to the enhanced hydrodynamic shielding. This helped us in devising quantitative guidelines for the optimum design of shear-stable and effective drag reducers. But then we needed some ideas from chemistry to exploit this further. The final idea was to introduce some chemical moieties with interacting functionalities on the backbone of a polymer to bring in the association effect. We created a shear-stable drag reducer by using hydrogen bonding as a tool, which led to an interpolymer complex formed when dilute solutions of two polymers bearing complementary proton-accepting and proton-donating functional groups were mixed[76,77]. Zipped chains of the kind shown in Figure 12 were formed, with the 'zips' occurring due to hydrogen bonding. Such zipped molecules were far more shear-stable and also provided 2–6 times higher levels of drag reduction.

18

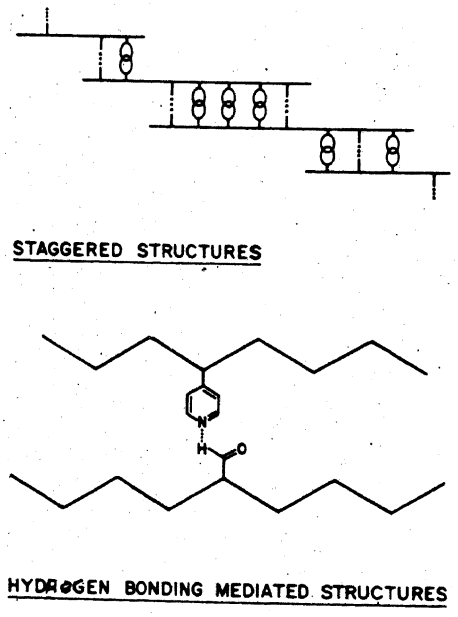

Figure 12. Design of shear-stable polymers by using hydrogen-bonding-mediated copolymeric structures, proton acceptor (containing 4-vinyl pyridine) and proton donor chains (containing methacrylic acid) create the staggered structures, which provide enhanced drag reduction[77].

The key point is that as CE scientists we had to take the clues from developments in polymer physics, perform an analysis based on a molecular model and finally shift to chemical synthesis of hydrogen-bonding-mediated systems to arrive at more effective systems. Remaining borderless or not shifting from 'analysis' to 'synthesis' would not have helped us to make progress. Of course, it is not that we claim that the problem of having shear-stable polymeric drag reducers is solved – but at least a modest beginning has been made.

Creating the seamless chemical engineering science: Some concerns

I have spoken on seamless chemical engineering science. I have referred to how the boundaries between different disciplines of sciences as well as engineering science are vanishing today. How do we make this boundaryless world work though? Let me now discuss some of my concerns in this respect.

First of all we all live in a world of very high specialization. This automatically implies that we are continuously erecting our own new boundaries, creating our own small clubs and generating our own special language and jargon all the time. However, boundarylessness implies interconnectedness. There itself lies the contradiction! How do we take care of these contradictions?

Another problem is that of dealing with adjacent sciences, where new mergers are continuously taking place and new territories are being continuously built. How do we deal with a moving target? What happens, for instance, when chemistry itself starts merging its boundaries with other disciplines, such as biology, in a profound way? Let me explain my worries by giving a specific example of the way chemists are trying to meet the challenge of generating and identifying biologically active compounds for pharmaceutical developments. Here, ideally, one would like to have access to an infinite source of compounds, encompassing the entire realm of structural and conformational space, that could be screened rapidly for individual molecules with desired biological properties. Chemists have now moved to combinatorial methods in biology and chemistry, which are powerful methods for generating molecular diversity (Figure 13). One approach, light-directed chemical synthesis, combines semiconductor-based photolithography technologies with solid-phase organic chemistry to synthesize large arrays of molecules with potential biological activity. A CE scientist is then confounded with the prospect of dealing with a phenomenon of rapidly emerging area, where boundaries between several adjacent disciplines have vanished. How does he cope with this challenge?

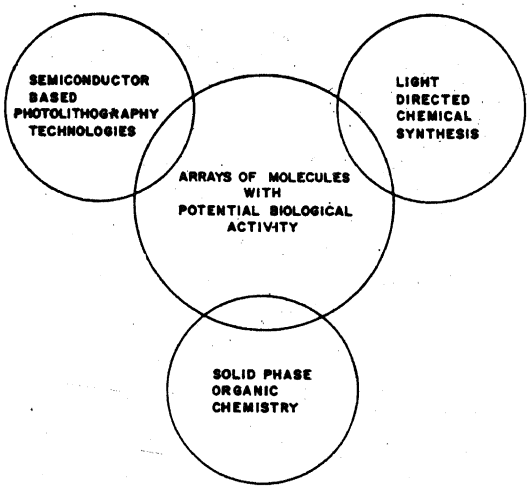

Figure 13. The principle of combinatorial chemistry, which combines diverse skills and technologies.

Then there is the problem of the language and the cultural barriers between different disciplines. Learning the language from another discipline and also teaching the language of CES to another discipline is not an easy job. Only those CE scientists who have dared to learn other skills and languages from adjacent disciplines will eventually make a mark. It also seems to me that interdisciplinary scientists will have to be great communicators too. They will have to constantly exchange information in a 'jargonless' way and also pass on their infectious enthusiasm by communicating well.

A CE scientist picks up tools and ideas generated in adjacent sciences and begins to publish papers in hardcore leading journals in chemical engineering. However, the elegance of the new tools or the sophistication of the new language may be mistaken for *novelty* and the problem solved may indeed be a trivial one. Many times a new tool from adjacent science, just because of its glamour value, may be applied to a trivial CE problem, which may not require that sophistication at all. This is misuse of tools and should be guarded against.

What are the forums for the presentation of results of research in interdisciplinary fields? Not many, I am afraid. More and more specialized clubs are mushrooming with little or no interaction between them. I saw someone make a suggestion that in a CES symposium dealing with an interface problem with other sciences, we should invite some scientists who may be able to give an alternative viewpoint. However, he was promptly turned down. Have we become too parochial? Will we be able to make progress if we continue this way?

We have another problem of peer recognition for those who work in interdisciplinary areas. As someone involved with the election of the Fellows of the National Academy of Science and National Academy of Engineering, I have found that engineers and scientists who are working on borders or trying to fuse these borders end up in difficulty in seeking recognition. Invariably, they fall between stools. Thus, somebody working in biomedical electronics does not get considered in either medical sciences or engineering sciences committees. Where does he go then? This is truly demotivating. The academies will have to recognize this problem and evolve special ways of solving these problems.

Many chemical engineering departments have recognized today the importance of having basic scientists with training and research experience from non-CE areas, be they in natural sciences or other branches of engineering. Thus, a chemical engineering department might employ an NMR specialist or a solid-state chemist. Sometimes the cultural and language barriers posed before these new entrants create great difficulties. A long time passes before they are accepted as part of the family. While speaking to some of them, it became clear to me that they also face difficulties on acceptance in academies or professional bodies. For instance, a physicist specializing in NMR in a chemical engineering department and applying NMR for solving problems of interest to chemical engineers does not get accepted as a Fellow of the Institute of Physics. At the same time the concerned Institute of Chemical Engineers also turns him down because it looks at his basic qualifications and finds that he is a non-chemical engineer! What a penalty to pay for working on borderline areas! Should not our professional bodies reexamine this and take new and bold approaches?

Then there is the question of how far does an engineering scientist go. There are some shining examples in our profession. Mark Davis from Virginia Polytechnic was educated as a traditional chemical engineer. He did his Ph D in kinetics and mathematical modelling. He wrote a book on numerical methods for chemical engineers. Then he contributed to the synthesis of zeolite A containing a transition metal. He exploited the use of ESR in the study of zeolites. Finally, he succeeded in synthesizing zeolite VPI-5, the first 18-ring opening crystal, which sparked off a renaissance in zeolite synthesis! A CE scientist is so well endowed due to his training that, if he dares to learn, he can conquer many territories. Extending this theme, I have reconsidered (Figure 14) the molecular heterogeneous hexagon conceptualized by van Santen[78]. It is clear that CE scientists will invade this hexagon in years to come with telling results!

With the boundaries between engineering science and science themselves merging, some basic conflicts are likely to arise. What is the role of an engineer and what is the role of a scientist? To my mind, a scientist 'explores', whereas an engineer 'exploits'. I looked for a

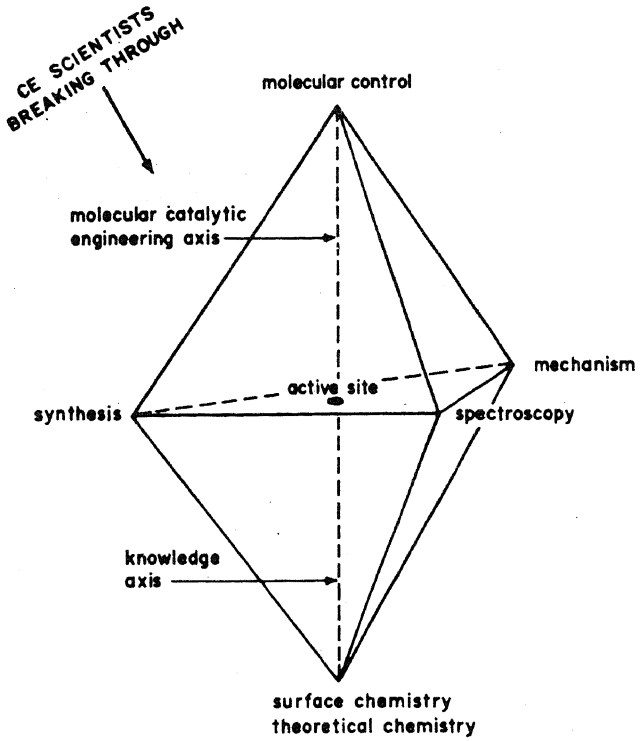

Figure 14. Molecular heterogeneous hexagon model due to van Santen[78]. Note the entry of CE scientists into this hexagon.

good definition of a scientist. I found one provided by Sir Peter Medawar. He says: 'A scientist is one, who weighs the earth and ascertains the temperature of the sun. He destroys matter and invents new forms of matter and one day he will invent new forms of life.' Then I looked for a definition of an engineer and found one given by Eric Laithwaite. He built on Sir Peter Medawar's definition and said: 'An engineer is one who uses the earth and tries to capture the sun's energy more effectively. He controls the rate of destruction of matter and tries to find alternative sources of energy and new materials. He invents new shapes of matter and strives to improve the quality of life in whatever form he finds it.' The basic goals of exploration and exploitation could not have been spelt out more clearly.

And that is precisely the problem that I am more concerned with. How does a CE scientist ensure that rather than getting possessed by the new tool that he has picked up and rather than spending all his research career on sharpening and refining this tool, does he bring benefit to the profession by using this tool in problem solving? Let me illustrate this point by going back to my early remarks about nonlinear dynamics and CES–physics interface.

Coupling between different nonlinear systems to bring about synchronization of states holds significant promise for future technology developments. Already, a few examples of the use of these concepts have emerged. Consider the spectacular success in enhancing the power of lasers by coupling them under chaotic conditions. In spite of the scores of papers on deterministic chaos, why is it that the CE scientists have not directed their attention to using this powerful technique to bring in similar spectacular results by, say, coupling chemical reactors? Here one is almost reminded of an inventor who endlessly refines his models but shies away from making a start for the fear that the real thing will not fly!

The challenges of the future will have to be met through both continuity and change. CES will extend itself, on the one hand, to the molecular focus of microscale processing and, on the other, to macroscale integration of processes and systems. Enormous flexibility and bewildering breadth have been the cornerstones of CES. However, the demand for enhanced flexibility in our approaches will be even higher in the coming years. The role of a CE scientist in this regard will be most crucial. He will have to be both very daring and innovative. In order to search for new tools and ideas, he may have to travel to the depths of the seas, climb new heights of the mountains, or he may have to go deep into the forests. If he does not dare to learn from other disciplines, then he will not be able to bring these jewels – these new ideas. The experience is that whenever this has happened, the results have been rewarding. Beckett *et al.*[79] borrowed the 'cold extrusion' idea from plastics and successfully applied it for the first time to milk chocolate, which is always melt-processed. This has opened up now endless possibilities of using plastics-processing techniques in chocolate processing. A CE scientist must not only dare to learn but he must also learn to dare.

Continuous improvements are fine – but discontinuities in knowledge create new technologies and that would not happen unless he dares. And most crucially, unless a CE scientist is himself 'boundaryless' and believes in seamless CES, all this will not happen.

Let us again remind ourselves that the word 'engineer' comes from the French word 'ingenieur', which literally means 'an ingenious one'. To my mind, our ingenuity of exploring the new tools of knowledge from adjacent disciplines is going to be the key to our success. Finally, I would like to repeat the inspiring inscription on the Lamme Medal of The Institute of Electrical and Electronics Engineers, USA, which simply says: 'The engineer views hopefully the hitherto unattainable.' I firmly believe that it is in this new seamless world of chemical engineering science that the CE scientists will not only 'view' the unattainable but also 'attain' the unattainable.

REVIEW ARTICLE

The neurotransmitter receptor triad: Nicotinic acetylcholine receptor, γ-aminobutyric acid receptor (type A) and inhibitory glycine receptor

P. R. Satish and A. S. Balasubramanian

Department of Neurological Sciences, Christian Medical College Hospital, Vellore 632 004, India.

Many different neuroactive substances known as neurotransmitters, which are involved in signal transduction, bind to specific membrane receptors in the vertebrate central nervous system. Of particular interest are the similarities shared by the nicotinic acetylcholine receptor, γ-aminobutyric acid receptor and inhibitory glycine receptor with respect to their pentameric structure, their neurotransmitter binding pockets, and colocalization with gephyrin. All three receptors undergo phosphorylation catalysed by protein kinases A and C. The biochemical defects in relation to these receptors result in the clinical manifestation of certain human disorders.

RECENT studies have indicated that the agonist binding pockets of the excitatory nicotinic acetylcholine receptor (nAChR), the inhibitory γ-amino butyric acid receptor subtype A ($GABA_AR$) and the inhibitory neuronal glycine receptor (GlyR) are formed from conserved amino acid positions in the extracellular domains of the ligand-binding subunits. Alignment of the subunit sequences of these three receptors shows that a motif of aromatic side-chains equivalent to positions 159–161 of GlyR α1 subunit is highly conserved at the homologous positions of the ligand-binding $GABA_AR$ and nAChR proteins (Figure 1).

It has been demonstrated that the exchange of the aromatic residues at positions 159 and 161 of GlyR generates receptors that are preferentially gated by agonists with longer carbon chains, such as β-alanine, taurine or γ-amino butyric acid (GABA). Moreover, it was shown that the replacement of phenyl alanine at position 159 by a tyrosine residue was sufficient to convert the GlyR into GABA-responsive protein[1].

Another feature indicating a close relationship between nAChR, $GABA_AR$ and GlyR is the colocalization of gephyrin, a peripheral membrane protein, with GlyR-, nAChR- and $GABA_AR$-containing areas of brain. Further, experimental results indicate that determinants of subunit assembly are in part located at homologous positions in these three ligand-gated ion channel proteins[2–4].

The main objective of the following sections is to discuss the biochemistry of the ligand-gated ion channels (with emphasis laid on nAChR, $GABA_AR$ and GlyR), their modulation by phosphorylation and the defects underlying specific human disorders in relation to these receptors.

The biochemistry of ligand-gated ion channels

Ligand-gated ion channels constitute one of the two major classes of neurotransmitter receptors[5]. These are multimeric protein complexes; they serve to transduce the extracellular signals to the cell interior by acting, as their name suggests, as ion channels. The binding of their respective ligands induces the opening of these channels, which are then rendered permeable to specific ions. They are then said to convert the chemical signal (ligand binding) released from one cell into an electrical signal (hyperpolarization or depolarization) that propagates along the target cell membrane. Thus, they provide for rapid dialogue between cells of the central nervous system. (This class is exemplified by the excitatory nAChR, the inhibitory GlyR, the inhibitory $GABA_AR$, etc.).

To date six families of ligand-gated ion channel receptors that mediate information in brain and neuromuscular junction have been characterized at the level of their amino acid sequences[6,7]. They are: (i) the excitatory nAChRs of neuromuscular and neuronal origin, which conduct cations; (ii) the excitatory neuronal kainate-type glutamate-activated channels, which conduct cations;

GlyR	α1	154	M Q L E S	F G Y	T M N D L
GABA R A	α1	155	L K F G S	Y A Y	T R A E V
GABA R A	β1	152	L E I E S	Y G Y	T T D D I
nAChR	β1	144	M K L G T	W T Y	D G S V V

Figure 1. Alignment of partial GlyR, $GABA_AR$ and nAChR subunit sequences. The regions homologous to amino acids 154–166 of the GlyR1 subunit are shown; amino acids homologous to residues 159–161 of the GlyRα subunit are boxed. (Based on ref. 1)

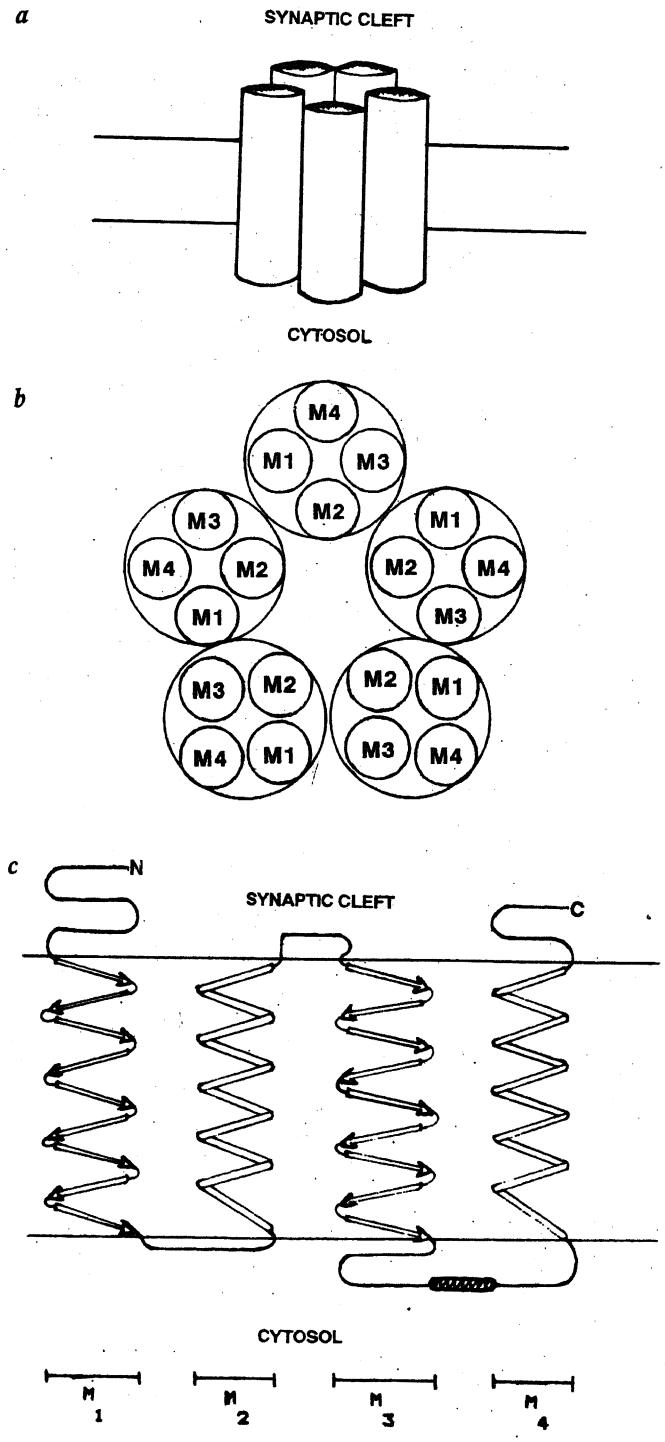

Figure 2. Schematic model of the topology of an idealized ligand-gated ion channel. *a*, Pentameric subunit structure viewed through an angle to the plane of the membrane. *b*, Schematic model representing the arrangement of the transmembrane domains, namely M_1, M_2, M_3 and M_4 (depicted as smaller circles) within each subunit (the larger circles) around the central ion channel (based on ref. 8). *c*, Membrane topology of an individual subunit containing transmembrane domains $M_1 - M_4$, viewed through the plane of the membrane. The hatched rectangle indicates the region of the subunit that contains the phosphorylation sites for various protein kinases. (Based on ref. 56)

(iii) the excitatory neuronal serotonin receptor (5-HT_3 receptor), which also conducts cations; (iv) the inhibitory neuronal GlyR, which conducts chloride; (v) the inhibitory neuronal $GABA_AR$, which also conducts chloride; and (vi) the sarcoplasmic reticulum ryanodine receptor, which conducts calcium.

These ligand-gated ion channel neurotransmitter receptors are pentameric complexes of subunits which are integral membrane proteins arranged around a central aqueous pore (Figure 2*a*, *b*)[8]. In a given receptor, these subunits reveal a high degree of sequence homology[9]. The sequence identity extends to other classes of receptors too. The hydropathy profiles displayed by the subunits of different families of these receptors are similar, suggesting that all possess a common transmembrane folding[9–14]. They are, therefore, said to form a superfamily of ligand-gated ion channels.

The minimal model for transmembrane organization of the subunits, which was proposed for Torpedo nAChR subunits[15,16], has been extended to all members of the superfamily[8]. It consists of

(a) a hydrophilic N-terminal domain oriented towards the synaptic cleft and carrying the glycosylated moieties,

(b) a compact hydrophobic region subdivided into three uncharged segments long enough to span the membranes and referred to as M_1, M_2 and M_3,

(c) a hydrophilic domain oriented towards the cytosol, which carries the consensus site for phosphorylation, and

(d) a short carboxy terminal hydrophobic transmembrane segment denoted as M_4.

In this minimal model both the N- and C-terminals are oriented towards the synaptic cleft (Figure 2*c*)[9]. However, this view has recently been challenged for glutamate receptor[17].

The extracellular domain of each of the receptor subunits forms a cylindrical vestibule which extends above the membrane plane. The agonist binding domains are located on the N-terminal domain and the cylindrical vestibule forms the ion channel, which lies along the axis of pseudosymmetry of the molecule[6]. Accordingly, the agonist site and the ion channel are topographically distinct. Hence, indirect or allosteric interactions account for the opening of the ion channels by their respective ligands[18].

Directed mutagenesis of the receptor subunits coupled with their transient expression in Xenopus oocytes has suggested that among the four hydrophobic putative membrane-spanning regions, namely M_1, M_2, M_3 and M_4, primarily M_2 and then M_1 and M_3 are most critical, and M_4 is the least required for ion conductance[5]. Therefore, each of the subunits contributes its M_2 region to line the inner wall of the ion channel[6,9]. Superimposed rings of charged residues bordering the M_2 regions of

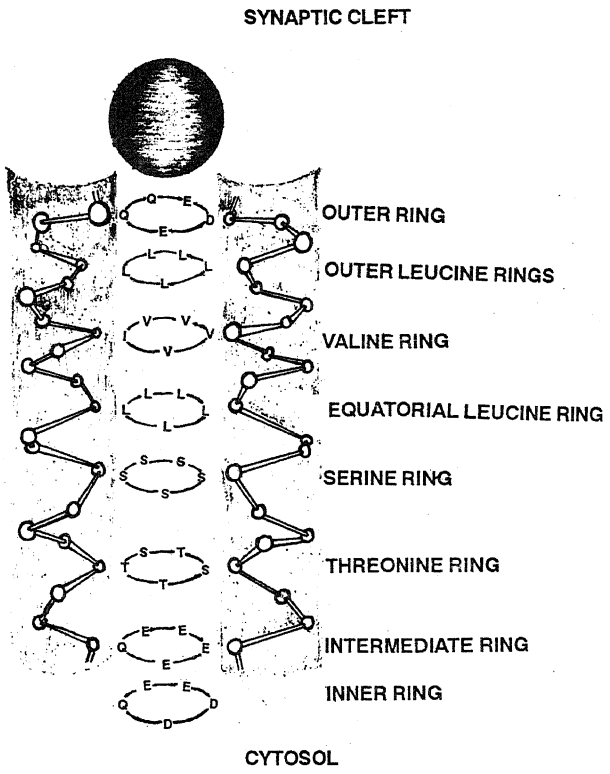

Figure 3. The arrangement of the M_2 segments of two subunits as transmembrane helices, wherein the superimposed rings of amino acids line the lumen of the ion channel. The channel is framed by rings of negatively charged amino acids at both the ends; these are called the inner ring and the intermediate ring at the cytosolic end, and the outer ring at the synaptic cleft end. At a low divalent ion concentration, removal of negative charges at these positions reduces both the inward and the outward currents. The other rings (from N- to C-terminal end) of the M_2 segments are: threonine ring, serine ring, equatorial leucine ring, valine ring and outer leucine ring. (Based on ref. 9)

the receptor have been shown to determine the conductivity of the ion channel (Figure 3). In all the subunits, charged amino acids are present at both ends of M_2.

In fact, high channel conductance of nAChR for cations is due in part to the negatively charged vestibule. The expected net negative charge within the vestibule is in excess of 10 negative charges, comprised of 31 negative and 21 positive groups. This excess negative charge density results in the repulsion of anions and concentration of cations in the channel mouth[19].

Significant in this regard is the fact that, $GABA_AR$ and GlyR, which conduct chloride ions (anions), have excess positive charge of about the same amount in their vestibular region. This suggests that charged vestibules may be a general mechanism of enhancing cation or anion selectivity[6].

The nAChR has a subunit stoichiometry of $\alpha_2\beta\gamma\delta$ in the neuromuscular junction[20], whereas it is just $\alpha_2\beta_3$ in the central nervous system and autonomic ganglia[21].

The subunit stoichiometry of GlyR which mediates synaptic inhibition in brain stem and spinal cord areas of the central nervous system (CNS) has been established[10] to be $\alpha_3\beta_2$, but which of the six α, four β, three γ, one δ and one ρ subunits comprise the $GABA_AR$ which mediates synaptic inhibition in other areas of the CNS is unclear as yet[22].

GlyR (ref. 23) and $GABA_AR$ (ref. 24) have been purified, and the amino acid sequence of their subunits and their functional expression studied[10–12]. Their subunits show sequence homology with each other to such an extent that the mutation of only two amino acids of the subunit of the GlyR renders it responsive to GABA[1,25]. These subunits have significant homology with the nAChR subunits also, further stressing the fact that all three receptors have a close relationship[1,7,9–12].

The combination of ion channels expressed by a neuron is responsible for its unique electrical properties like excitability and ability to propagate action potentials. The permeability of these ion channels to their respective ions, in addition to being regulated by membrane potential (in voltage-gated ion channels) and neurotransmitters (in ligand-gated ion channels), is also altered by protein phosphorylation[26].

Protein phosphorylation

Four decades since the first report implicating it in glycogen metabolism, protein phosphorylation has now come about to be acknowledged as the most common posttranslational modification involved in the regulation of protein functions.

Protein phosphorylation is regarded as the fundamental event in most cellular processes, and especially so in signal transduction[27,28]. Signals impinging on cells have their effects amplified and disseminated by a network of protein phosphorylation and dephosphorylation systems; the enzymes catalysing these reactions are further subject to control via cascades of phosphorylation and dephosphorylation reactions. Phosphorylation has also been shown to mediate many actions of the second messengers. Most extracellular signals including hormones, growth factors, neurotransmitters, electric potential and components of extracellular matrix alter the state of phosphorylation of intracellular proteins. These extracellular signals modify the activities of kinases and/or phosphatases either directly (e.g. receptors with kinase activity) or via cascades of enzymatic reactions (e.g. receptors–G-proteins–enzyme–second-messenger–protein-kinase) (Figure 4)[26]. Such cascades involving second messenger and protein kinase systems display a number of properties which allow amplification, integration, convergence and modulation of multiple and simultaneous internal and external signals.

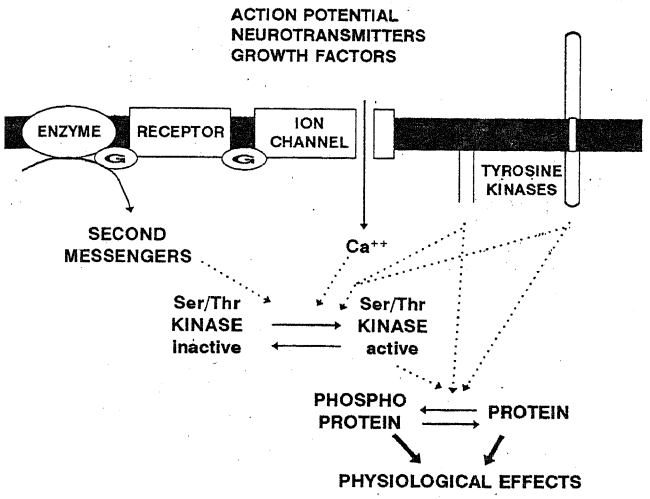

Figure 4. Schematic representation of some pathways by which extracellular signals alter protein phosphorylation in neurons. G in the figure indicates G (guanine nucleotide binding) protein.

Moreover, since the properties of many enzymatic components of signal transduction pathways are themselves altered by phosphorylation, the responsiveness of a cell to extracellular signal depends in part on the extent to which its proteins are phosphorylated. In other words, the cell keeps track of its recent history, encoded in its pattern of protein phosphorylation. Thus, protein phosphorylation allows not only the transduction of extracellular signals into the biochemical reactions inside the cells, but also the computation of several extracellular signals and their integration over time. It is, therefore, not surprising that most of the protein kinases and phosphatases are highly expressed in neurons, which are cells specialized in information processing[26].

Many proteins that are involved in synaptic function have been shown to be phosphorylated. These include proteins which play a role in neurotransmitter synthesis and release, voltage-gated ion channels, ligand-gated ion channels and G-protein-linked neurotransmitter receptors. The ion channels are a particularly appropriate target for the modulation of synaptic transmission by protein phosphorylation, since they are central to the process of signal transduction across the postsynaptic membrane[5,29].

Phosphorylation of the ligand-gated ion channels

Nicotinic acetylcholine receptor phosphorylation

Phosphorylation of nAChR has been extensively studied and documented[30,31]. One of the characteristics recorded for nAChR is its desensitization. In the continued presence of the agonist, the receptor rapidly fluctuates between conducting and nonconducting states for several hundred milliseconds and then enters a nonconducting, no-longer responsive desensitized state.

A comparison of the properties of the phosphorylated and nonphosphorylated nAChR shows that the rate of desensitization is enhanced in phosphorylated nAChR[32], whereas the channel conductance and the mean channel open time are not altered. Protein kinase activators like cyclic adenosine monophosphate (cAMP) analogues and phorbol esters are also recorded to enhance the rate of desensitization of nAChRs in different cell lines[33–36].

Tyrosine phosphorylation of nAChR is known to occur subsequent to innervation of muscle during development and is abolished by denervation. These findings establish the role of the neuron in regulating nAChR tyrosine phosphorylation[8].

Extracellular signals that are potential regulators of protein tyrosine phosphorylation have been investigated for their effect on the phosphorylation of nAChR. Agrin and basic fibroblast growth factor (bFGF) are the two well-documented examples. Agrin is known to induce tyrosine phosphorylation of nAChR in cultured myotubes[38] and the bFGF receptor is known to be a tyrosine kinase[37]. Whereas agrin mediates the nerve-induced aggregation of nAChR beneath the nerve terminals[8], bFGF bound to latex beads induces nAChR cluster formation in the Xenopus myoblast, at the bead myoblast contact point.

Drugs which inhibit tyrosine phosphorylation block both agrin-induced and bFGF-induced nAChR clustering[38]. Thus, tyrosine phosphorylation of nAChR most probably alters its interaction with the cytoskeleton in such a way as to cause the receptor immobilization, which results in accumulation of the receptor aggregates at the synaptic sites.

Phosphorylation of nAChR by calcium-diacylglycerol-regulated protein kinase or protein kinase C (PKC) in cultured chick myotubes results in the dispersal of nAChR aggregates and dephosphorylation promotes aggregation of the receptor. Diagonally opposite results are observed when phosphorylation due to cAMP-dependent protein kinase or protein kinase A (PKA) is activated[39].

All these facts suggest that phosphorylation, apart from enhancing the rate of desensitization of nAChR, also plays a vital role in its assembly and aggregation during synaptogenesis.

Recently, the autoregulation of phosphorylation of nAChR has been reported. This reveals a novel signal transduction pathway whereby the nAChR may regulate its own functional activity through phosphorylation[40].

GABA receptor phosphorylation

The evidence for direct modulation of GABA receptor function by phosphorylation is compelling. A basal-level

phosphorylation appears necessary to maintain $GABA_AR$ function[41]. Further, kinases activated in response to intracellular second messengers have been shown to regulate $GABA_AR$, resulting in a variety of functional effects, sometimes contradictory[42–44].

In different systems, for instance, PKA activation can potentiate, inhibit or have no effect on the amplitude of the GABA-elicited currents[45].

Phosphorylation due to PKC has been shown to decrease the current amplitude of some, but not all, GABA receptors.

These differential effects may be due to indirect effects of phosphorylation of other regulatory proteins; of equal importance is the fact that the functional properties of a given GABA receptor depend on the subunit composition. Different combinations of these subunits render the receptor responsive to different agonists and to a varied extent to the same agonist/antagonist[6,22].

Ethanol, man's most widely used and oldest psychoactive drug, acts by inducing the opening of $GABA_AR$ chloride ion channel. Recently, it has been reported that the alternatively spliced intracellular segment of the γ_2 subunit (namely, γ_2L, which has an eight amino acid insert), is required for the ethanol sensitivity in some GABA receptors. It is interesting to note that this intracellular segment contains a consensus PKC phosphorylation site[46]. Hence, it is possible that phosphorylation is involved in regulating receptor modulation at the ethanol-sensitive site.

Thus, in addition to their direct effects, intracellular phosphorylation events may also regulate GABA receptor more indirectly through effects on other modulatory sites.

Glycine receptor phosphorylation

GlyR can be phosphorylated both *in vitro* and *in vivo*, in response to PKA or PKC activators[47]. In Xenopus oocytes PKC activators decrease glycine-induced currents while PKA modulators increase the response to glycine. Although such data do not provide evidence for the actual phosphorylation of glycine receptor channels in the oocytes, the results obtained in intact spinal cord cells are consistent with a direct effect of phosphorylation in receptor function.

Given the variety of neurotransmitters, neuropeptides and growth factors known to regulate the intracellular activities of these two protein kinases, the fact that they modulate GlyR gives rise to intriguing possibilities, especially in the glycinergic neurotransmission in the spinal cord[48]. The dual mechanism of regulation by PKA and PKC modulators provides a sensitive instrument for the integrated modulation of the receptor by other extracellular messengers acting on the same neuron. This includes the previous, simultaneous or subsequent activation of a variety of G-protein-coupled receptors known to cause changes in cAMP or diacyl glycerol levels, which would further lead to changes in the subsequent neuronal response to glycine.

GlyR phosphorylation may prove to be a common mechanism by which the inhibitory action of glycine is regulated. This possibility is appealing, especially in case of pain transmission neurons. Two neurotransmitters, namely 5-hydroxytryptamine and noradrenaline, have important roles in the control of pain transmission at medulla and spinal levels. They are also known to alter the cAMP levels in target cells through their specific receptors. Thus, their observed effects may be mediated through the cAMP-dependent potentiation of inhibitory glycinergic transmission. Therefore, although further investigation is necessary, GlyR phosphorylation represents an attractive mechanism for the supraspinal regulation of some spinal cord processes. The integration of such cross-talking mechanisms of the neuronal membrane level accounts for transient and long-term changes in the efficacy of synaptic transmission, thus contributing to synaptic plasticity.

The defects underlying human disorders related to the neuroreceptors nAChR, $GABA_AR$ and GlyR

nAChR

Myasthenia gravis (MG) is a neuromuscular disorder characterized by weakness and fatigability of skeletal muscles. The underlying defect is a decrease in the number of available nAChRs at the neuromuscular junctions, due to an antibody-mediated autoimmune attack. Anti-nAChR antibodies cause accelerated destruction and the functional impairment of nAChR and failure of neuromuscular transmission. These antibodies act by three distinct mechanisms:

1. nAChR may be degraded at an accelerated rate by a mechanism involving crosslinking of the receptors.
2. The site in nAChR that normally binds acetyl choline may be blocked by the antibodies.
3. The postsynaptic muscle membrane may be damaged by the antibody in collaboration with the complement.

Thymus plays a role in the process of manifestation of autoimmunity. Muscle-like cells within the thymus, called myoid cells, bear nAChR-like protein on their surface. This acetylcholine-receptor-like protein is a glycoprotein, binds α-bungarotoxin irreversibly and has strong structural similarities with muscle nAChR. Its molecular weight, isoelectric point and amino acid composition are all very similar to those of nAChR found in mammalian muscle and the fish electroplax. This protein

most probably serves as the source of autoantigen and triggers the autoimmune reaction within the thymus gland[49–51].

$GABA_AR$

Epilepsies are a group of disorders characterized by chronic, recurrent paroxysmal changes in the neurological function caused by abnormalities in the electrical activity in the brain. Each episode of neurological dysfunction is called a seizure. Seizures may be convulsive when they are accompanied by motor manifestations or other changes in neurological function[52].

Current thinking awards GABAergic mechanisms a central role in the pathogenesis and treatment of epilepsy. The strongest evidence for a role of GABA in epilepsy is the fact that the pharmacological enhancement of GABAergic function produces antiepileptic effect. Several anticonvulsant drugs, including barbiturates and benzodiazepines, enhance GABA action at its primary sites, namely the GABA-benzodiazepine chloride ion channel complex[53].

GABA agonists are predominantly inhibitory and antiepileptic, whereas GABA antagonists produce seizures. Experimental agents that inhibit the breakdown of GABA are also predominantly antiepileptic.

Additional confirmation of the importance of GABA in epilepsy comes from analysis of neurotransmitter markers from animal models of acquired and genetic epilepsy. Pathological analysis of brain tissue from epileptic patients using positron emission tomography indicates either abnormalities in or the loss of GABA/benzodiazepine receptors[53].

GlyR

Reduced glycinergic inhibition caused by subconvulsive strychnine poisoning results in muscular hypertonia, heightened reflex excitability and an exaggerated response to sensory stimuli. These symptoms are similar to those of the autosomal dominant neurological disorder called startle disease, also known as hyperekplexia or kok's disease. This disorder is characterized by a marked muscular hypertonia in infancy, and an exaggerated startle response to unexpected sensory stimuli persistent in adulthood. Sudden jerking of limbs, or occasionally of trunk muscles, is observed; sudden noise or touch may cause the subject to jump or to fling an extremity.

More recently, point mutations in the gene encoding the subunit of the glycine receptor have been identified in startle disease pedigrees. These mutations map to arginine 271 located at the extracellular margin of the channel-lining M_2 region. In startle pedigrees the arginine 271 is replaced by an uncharged amino acid leucine or glutamine[54].

Site-directed mutagenesis of the GlyR cDNA coupled with their expression in mammalian 293 cells and their further studies using patch clamp technique have led to the discovery that the startle disease mutations cause no major alterations in ion permeation through GlyR, but rather dramatically reduce the receptor's agonist sensitivity. This finding, in addition to explaining the startle disease phenotype, identifies an unexpected structural determinant of the GlyR function.

This apart, analysis of other startle disease mutations may provide further important insights into the mechanisms of activation of the ligand-gated ion channel receptor superfamily.

Interestingly, startle response (abnormally enhanced startle response to acoustic stimuli) is also observed as one of the manifestations in the calcium calmodulin kinase II (CaMkII) mutant mice developed by Silva *et al.*[55]. The startle response is not observed in the wild-type mice, which have intact CaMKII. Whether there is any relationship between the startle response due to defective GlyR and that due to the absence of CaMKII, and if yes, the question as to what is its nature, has to be addressed in future.

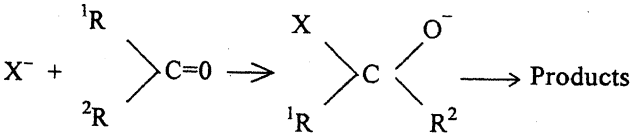
On the usefulness of quantum chemical bond order as a local reaction path indicator: The case study of a model carbonyl addition reaction†

D. K. Maity, D. Majumdar* and S. P. Bhattacharyya*

Chemistry Division, Bhabha Atomic Research Centre, Trombay, Bombay 400 085, India
*Department of Physical Chemistry, Indian Association for the Cultivation of Science, Jadavpur, Calcutta 700 032, India



The idea of using quantum chemical bond order (BO) as a local reaction path indicator proposed earlier with reference to ABC ↔ BCA type of isomerization processes is explored further with reference to model carbonyl addition reactions, e.g. $H_2CO + H–Cl \rightarrow H_2CCl–OH$ and $H_2COH^+ + H–Cl \rightarrow ClCH_2OH + H^+$. In each case the reaction is viewed as a superposition of elementary chemical events, some representing bond making and some bond breaking processes, respectively. Altogether four bonds are involved in the model. The active bond order profile in each case is marked by a sharp inflexion signalling the onset of a critical process, viz. bond breaking or bond making. An extended bond energy bond order description of the addition of HCl to the >C=O moiety is suggested and tested numerically. The semilocal description is seen to model the approximate reaction path well and predict the active portion of the transition state structure fairly successfully. The local RP modelling is also seen to predict changeover in the mechanism of the reaction when conditions are altered by protonating the carbonyl group. The origin of the observed BO inflexions is sought to be correlated with Fermi correlation.

CHEMICAL reactions involve breaking and making of bonds. These processes take place gradually along a certain path, the so-called reaction path (RP). The usual indicator of this path is energy and the abstraction of RP in theory is a curving, parabolic potential energy channel stretching from the reactants to the product valley on the potential energy surface (PES). The top of the path defines the so-called saddle point, the activation barrier and the structure of the associated transition state. Energy is, however, a global parameter of the entire system while intuitive visualization of a chemical reaction in terms of breaking and making of specific bonds relies on a more 'local' description. An essential ingredient of this picture is the assumption that the bonds being broken or formed are the 'active' or 'important' bonds while the other bonds are more or less 'spectator like' or 'passive' and do not play any decisive role in shaping at least the gross or dominant features of the RP.

In the recent years a number of reports dealing with the existence of inflexion points in reactive valence or bond order (BO) profiles have appeared[1–5]. It has also been conjectured that such an inflexion point in BO profile may even coincide with or be close to the saddle point on the reaction path[4,5]. The present communication explores the utility of these concepts further with the specific case of a prototypical carbonyl addition reaction which can be described in terms of a four-bond process. It is also shown that by isolating the active bonds and making use of the appropriate bond order conservation conditions, an extended bond energy bond order (EBEBO) description of the active portion of the transition state geometry can be arrived at and the minimum energy reaction path (MERP) constructed. Although the discussion that follows concerns a reaction in particular, the observations are quite general or further generalizable. It enhances the scope of applicability of the local description to much more[6] complex systems.

Carbonyl addition reaction

Addition of nucleophiles to carbonyl centres is a very fundamental process in organochemical and biochemical reactions. Common examples include hydrolysis of esters and amides, aldol condensation and numerous reactions of organometallic reagents and ylides[7–9]. Analysis of experimental results on these reactions has led to the following B_{AC}^2 mechanism for these processes[10];

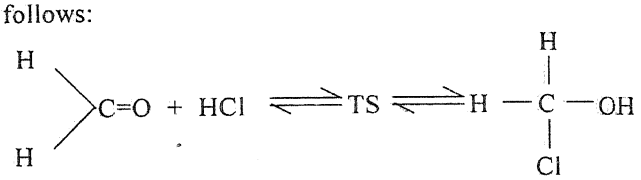
†Based on a lecture delivered by SPB in the 1993 mid-year meeting of the Indian Academy of Sciences, Bangalore.

Results of gas phase experiments have shown that esters undergo competitive proton transfer, eliminations and S_N2 reactions in favour of $B_{AC}2$ processes[11]. This $B_{AC}2$ mechanism has also been found to be operative for the gas phase additions to acyl halides[12]. Analysis of the kinetic results has led to the conclusion that the reactions in the gas phase feature a double-well potential surface with the tetrahedral species as a transition state and ion–dipole complexes as minima. Using crystallographic data for various nucleophilic groups interacting with different carbonyl centres, Burgi and Dunitz[13] were able to propose likely pathways for the approach of the nucleophile. Using SCF-LCAO-MO calculations[14] on the model addition reaction of hydride ion to formaldehyde, the same authors found no energy maxima in the potential energy profile. In a recent *ab initio* study on the addition of hydroxide ion to formaldehyde, Madura and Jorgensen[15], using a basis set containing diffuse functions, found a small local maxima in the energy profile of the reaction. Bayly and Grein[16] further confirmed that the reaction profiles for these addition reactions might be described adequately by adding diffuse functions to the basis set.

With this background in view, our purpose in the present communication has been to explore the possibility of (a) describing a simple carbonyl addition reaction quantitatively in terms of a rather *local* concept like variation of bond order, (b) constructing an *extended* bond energy bond order (semilocal) description of a process involving four active bonds, (c) using the local picture for predicting changeover in reaction mechanism, if any, when reaction conditions are altered, and (d) checking the validity of a *regional* or *local* hardness extremization principle proposed recently. The specific definition of bond order we choose to employ is due to Mayer[17]. The advantage of this quantity lies in its relative insensitivity to changes in the size of the basis set employed[18]. Irrespective of whether one is working in an *ab initio* or a semiempirical framework, the computed bond order index, which is a bond multiplicity index, turns out to be close to 1 for a single bond, 2 for a double bond, and so on. However, the minor method or basis dependence can be tackled by using renormalized BOs (see later). We have employed the standard AM1 method of Dewar and Thiel[19] with the hope of extending the present study, if useful, to reactions of different types involving much larger systems.

Method

The potential energy surface (PES) for the gas phase reactions studied in this paper has been computed by the standard AM1 Fletcher–Powell technique. For each point on the PES complete optimization of all geometrical parameters has been carried out. Bond orders have been calculated for each pair of atoms for all the relevant points on the RP. The generalized bond order (B_{XY}) between a pair of atoms (X and Y) is given by[17]



$$B_{XY} = \sum_{\mu \in X} \sum_{\nu \in Y} (\overline{D}S)_{\mu\nu}(\overline{D}S)_{\nu\mu} + \sum_{\mu \in X} \sum_{\nu \in Y} (D^{s}S)_{\mu\nu}(D^{s}S)_{\nu\mu}, \quad (1)$$

where the one-electron density matrix (ρ) in AO basis has been partitioned into $\overline{D}$ and D^s. $\overline{D}$ is the part of the one-electron density due to the core or the doubly occupied orbitals and D^s represents that due to singly occupied orbitals. At the AM1 or MNDO level of approximation, $S = 1$ and for closed shell systems $D^s = 0$, leading to corresponding simplifications in the expression for B_{XY} which now becomes identical with Wiberg's bond order[20].

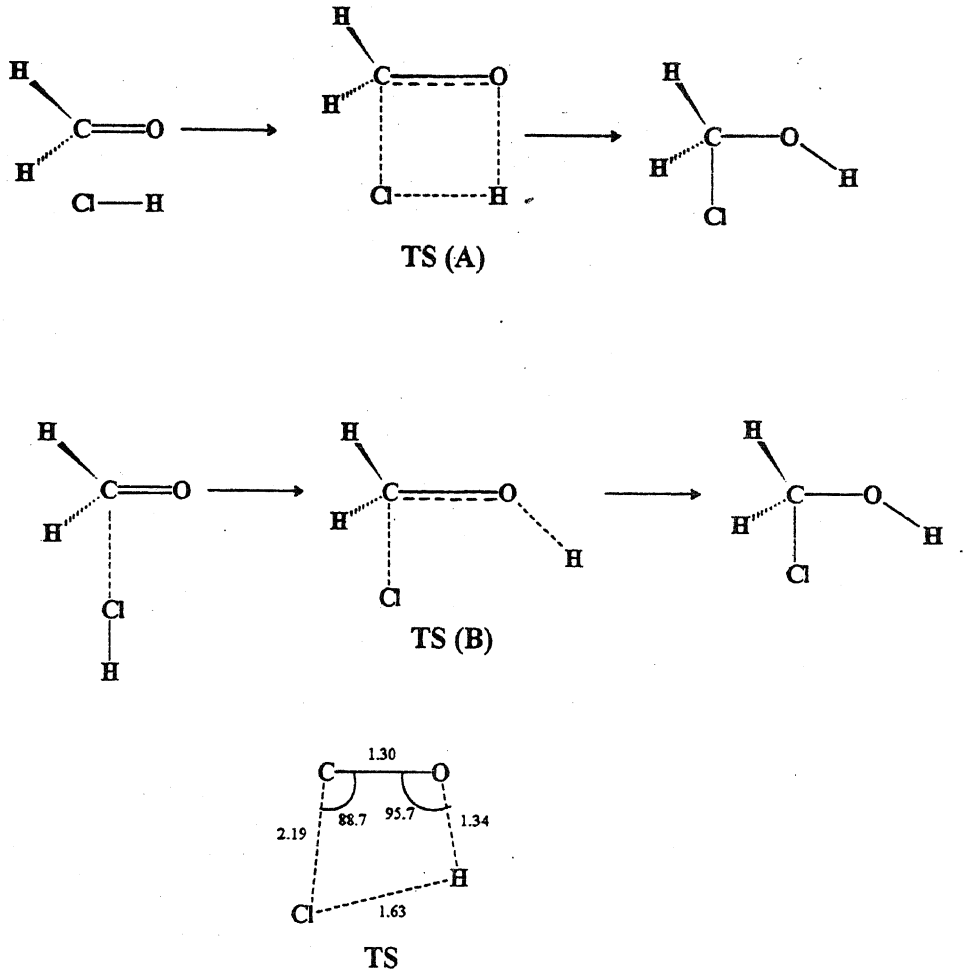
Results and discussion

Addition of HCl to H_2CO in the gas phase: a local versus global description

The gas phase reaction between formaldehyde and hydrogen chloride may be schematically represented as follows:

We have explored two different pathways (schemes A and B in Figure 1) for the reaction, each passing through a separate transition state [TS(A)/TS(B)]. In scheme A, the HCl molecule has been assumed to approach the carbonyl group laterally, leading to a four-centered transition state [TS(A)] as in Figure 1. In scheme B, the HCl molecule is assumed to approach the nucleophilic centre in a plane perpendicular to the plane containing the >C=O group, leading to a transition state [TS(B)] as in Figure 1. In both the cases the reaction coordinate (RC) involves a predominant participation of the effective C..Cl and O..H distances. However, scheme B turns out to be inappropriate as it fails to lead to any well-defined TS or to product. In scheme A, on the other hand, we find that the reaction proceeds through a well-defined TS characterized by the structure [TS(A)] shown in Figure 1. This TS has been located by varying the >C..Cl and O..H distances (r_1 and r_2) in a preset grid while all other geometrical parameters for each pair of values of r_1 and r_2 have been fully optimized by the Fletcher–Powell technique.

The energy profile along the reaction path is depicted in Figure 2 *a*. The location of the TS corresponds to a value of the path coordinate (PC) = 0.76. At this point on the RP, $r_1 (= r_{C..Cl}) = 2.19$ Å, $r_2 (= r_{O..H}) = 1.34$ Å, $r_{C..O} = 1.30$ Å and $r_{H..Cl} = 1.63$ Å



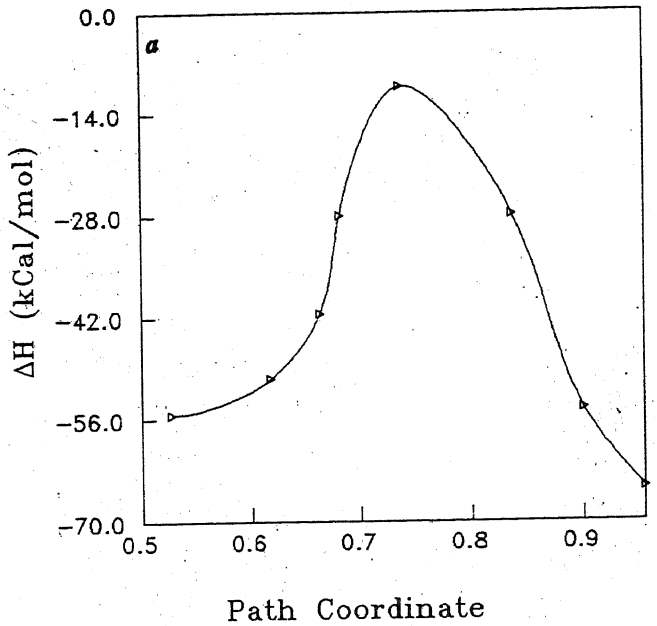


Figure 1. Reaction schemes (A and B) for the addition of HCl to H_2CO and optimized transition state geometry [TS(A)] for the lateral approach of HCl to the formaldehyde molecule.

(see Figure 1). Since the reaction scheme involves breaking of the H–Cl and p(C–O) bonds, respectively, and formation of a C . . Cl and an O..H bond, we designate them as 'active bonds'. A local model of the reaction should, therefore, be able to describe the process mainly in terms of quantities related to these four bonds only.

Figures 2 *b* and *c* display variations in H–Cl and O–H bond orders, respectively, as they change along RP, while Figure 3 *a* exhibits variations in the p bond order of the C–O bond as a function of the path coordinate. Variation in C–Cl bond order along the RP is also shown in the same figure (Figure 3 *b*). It is clearly seen that each of the H–Cl, C–Cl, C–O and O–H BO profiles reveals the occurrence of a definite and rather sharp point of inflexion. The C–Cl separation at the corresponding BO inflexion point is 2.19 Å, the H–Cl length is 1.63 Å , the C–O length is 1.30 Å and the O–H separation is 1.34 Å. If we compare these lengths with the bond length in the TS obtained by energy optimization route (i.e. by adopting a scheme of global RP analysis), we find that H–Cl, C–Cl, C–O and O–H bond lengths at the corresponding inflexion points match rather nicely with the corresponding bond lengths already found for the TS structure located on the given energy hypersurface.

It may be noted that the reaction in scheme A involves participation of four atoms (C, O, Cl and H). It would be of interest, therefore, to examine whether the total bonding capacity of the 'active atoms' is conserved along the MEP. We have, therefore, plotted the sum of the computed bond orders of the p(C–O), C–Cl, O–H and H–Cl bond (Figure 3 *c*) of the four relevant atoms along the RP. It is interesting to note that the so-called principle of bond order conservation (PBOC) advocated by Lendvay[2] appears to remain only approximately valid in this particular reaction in regions appreciably away from the critical region surrounding the saddle point. Around the saddle point, the active BO sum is not conserved. On the other hand, it passes through a minimum.

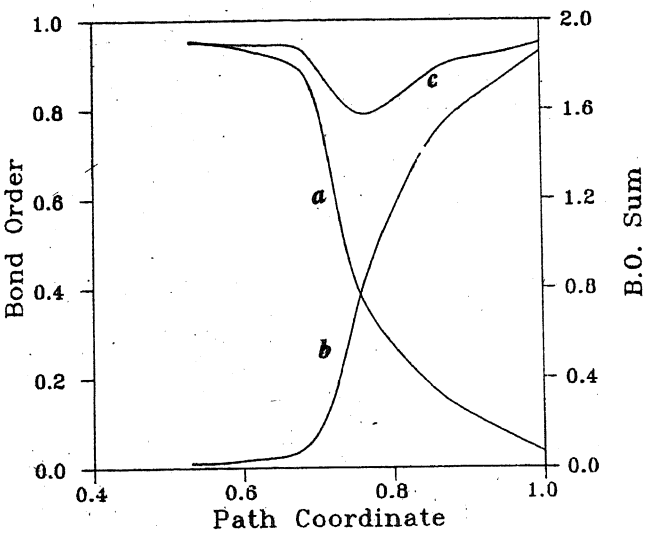

Figure 3. The BO profiles of: *a*, the Π (C–O) bond and *b*, the C–Cl bond along the reaction path for the gas phase addition of HCl to H_2CO. *c*, The extent of validity of the active BO sum conservation is shown for the carbonyl addition reaction.

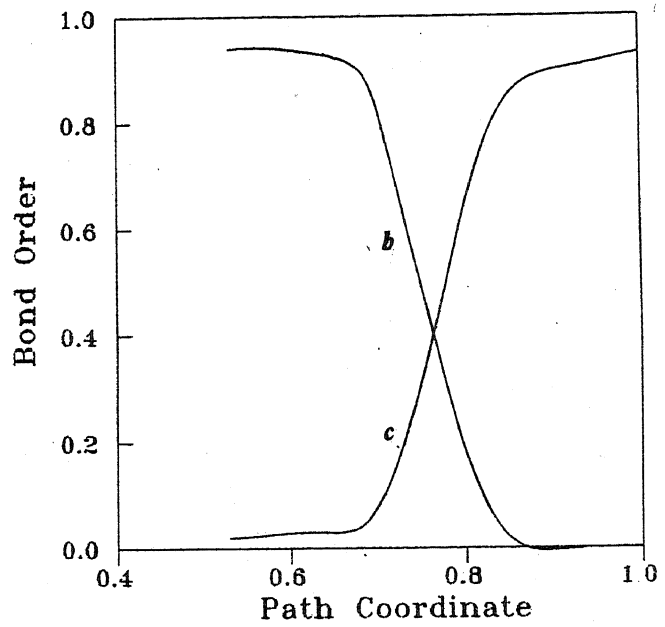

Figure 2. *a*, Energy profile in gas phase for formaldehyde +HCl reaction (scheme A): *b*, HCl bond order profile; *c*, O..H bond order profile along the RP.

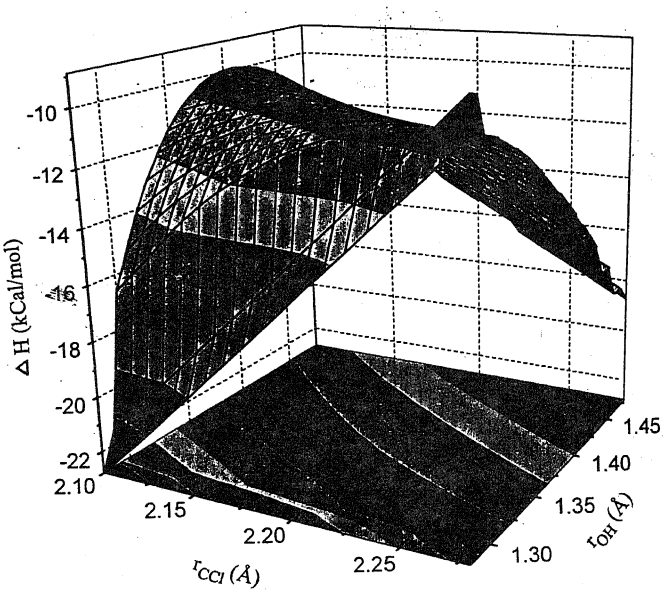

Figure 4. Energy contour as a function of O..H and C..Cl bond lengths for the formaldehyde +HCl reaction in the gas phase and the three-dimensional plot of the interaction energy. The transition state (×) on the reaction path (marked by the dotted line).

It has recently been shown that this behaviour of the active BO sum could amount to a local or regional softness or hardness extremization principle[21]. The saddle point, and the inflexion points in the BO profiles of the reaction under consideration occur almost at the same value of the path coordinate, viz PC = 0.76. The BO profiles of Figure 2 and 3, therefore, tend to suggest that the H–Cl, π(C–O), C–Cl and O–H bonds are each associated with a critical process occurring in the course of the reaction. They are then the active bonds. It would be worthwhile, therefore, to map the corresponding energy changes on the plane defined by the bond lengths of a pair of the active bonds, say C–Cl and O–H bonds. We have studied the reactive PES in three dimensions (two of these are the C–Cl (r_1) and O–H (r_2) bond lengths) and mapped its contour on the (r_1, r_2) plane. The energy map in two dimensions and the plot in three dimensions are displayed in Figure 4. The 'reaction path' has been marked on the contour map by a dotted line and the

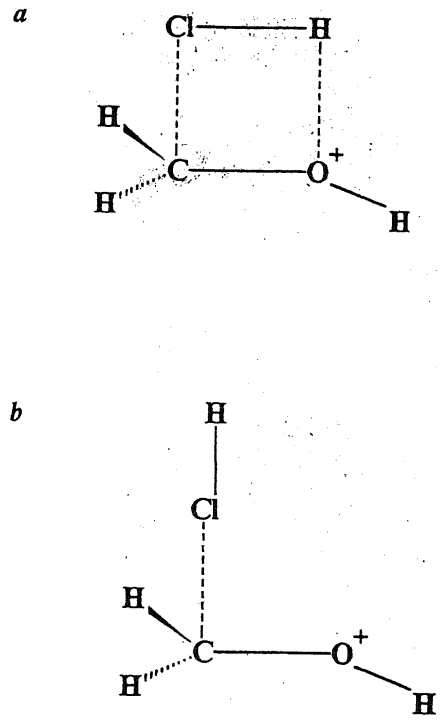

Figure 5. Schematic representation of: *a*, lateral and *b*, orthogonal approach of HCl to the protonated formaldehyde.

location of the TS by a cross (×) which corresponds to $r_1 = 2.19$ Å and $r_2 = 1.34$ Å. These values match well with those obtained from the points of inflexion on the BO profiles. The gas phase reaction is exoenergic by a small amount (5.34 kcal/mol) and the activation barrier turns out be ≈ 48.0 kcal/mol.

Gas phase addition of HCl to H_2COH^+: local description of mechanistic changeover

How would protonation of formaldehyde affect the course of addition of HCl to the carbonyl group? One can anticipate a drastic change in the mechanism since the addition of a proton would (i) severely distort the π electron distribution within the carbonyl moiety and (ii) create positive charge density on all atoms in the molecule. As expected, our calculations reveal the inappropriateness of the lateral approach, which fails to initiate the reaction (Figure 5 *a*). Initial search showed that the HCl molecule would prefer to approach the protonated >C=O group in a plane orthogonal to the plane containing the carbonyl group (Figure 5 *a*) with the Cl end pointing towards the carbonyl carbon atom. Figures 6 *a*

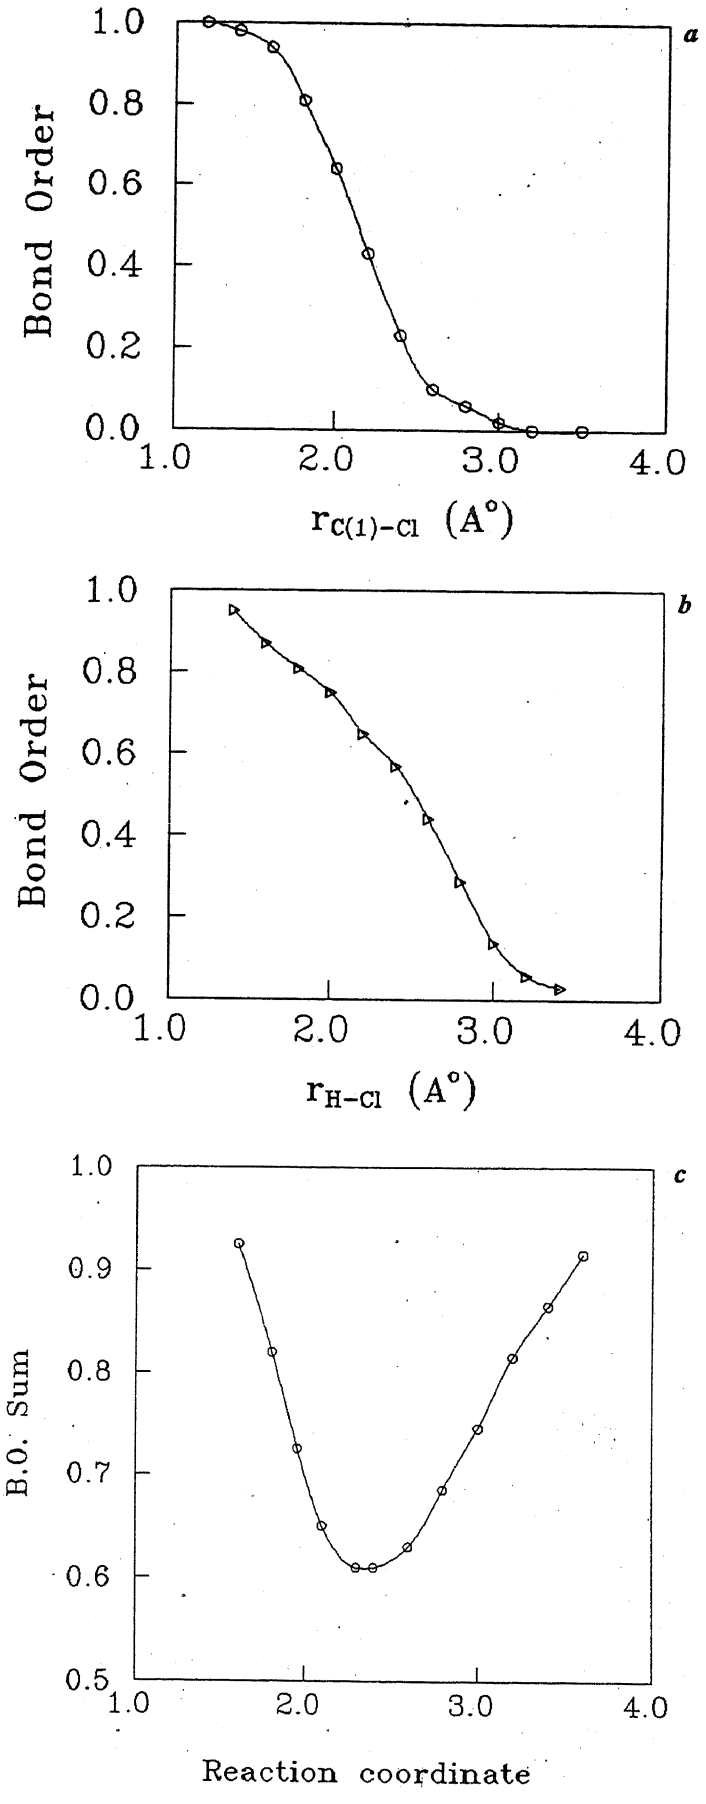

Figure 6. *a*, C–Cl bond order profile as a function of C..Cl bond distance; *b*, H–Cl BO profile as a function of H–Cl distance; *c*, sum of C–Cl and H–Cl BOs along the RP in the $HCl + H_2COH^+$ reaction.

and *b* present the H–Cl and C–Cl bond order profiles along the reaction path. These BO profiles, the active BO profiles, once again enable us to have a local description of the reaction in terms of elementary chemical events. It is interesting to note that the inflexion point in the BO profile of the H–Cl bond corresponds to an H–Cl distance of 2.75 Å when the C–Cl distance is about 2.25 Å. This C–Cl distance is much too large for any significant extent of C–Cl bond formation to have taken place. The inflexion point on the BO profile of the C–Cl bond itself, however, occurs only at a much shorter C–Cl length ($r_{C\text{–}Cl} \approx 2.08$ Å) indicating that the C–Cl bond formation takes place much later. In other words, *the breaking of the* H–Cl *bond does not synchronize with the formation of the* C–Cl *bond.* Obviously, this tends to suggest that the sum of H–Cl and C–Cl BOs is not conserved, a feature that is clearly seen to be true from Figure 6 *c*.

One can contemplate, therefore, that the mechanism of addition of HCl to H_2COH^+ could be fundamentally different from the mechanism established for the addition of HCl to unprotonated H_2CO. If the two asynchronous inflexion points, one rather early and the other late, observed in the H–Cl and C–Cl BO profiles, respectively, can be assumed to be associated with the physical process of bond breaking or making, one would be tempted to think that the addition of HCl to H_2COH^+ must be a two-step process. The H–Cl bond breaks first producing H^+ and Cl^-, the latter then attacking the carbon atom of the >C=O–H^+ group with the formation of chloromethanol. The entire process may be schematically represented as follows:

$$H_2CO + H^+ \rightarrow H_2COH^+,$$
$$HCl \rightarrow H^+ + Cl^-,$$
$$Cl^- + H_2COH^+ \rightarrow ClCH_2OH.$$

The inflexion that occurs in the C–Cl BO profile as Cl^- attacks H_2COH^+ is not very sharp, indicating that the associated energy profile also would be relatively featureless. Figure 7 *a* shows the energy profile for the first step when HCl approaches the carbonyl carbon atom of the protonated formaldehyde in an orthogonal plane. A small hump appears followed by a monotonic decrease in the total energy. The location of the hump corresponds to $r_{C\text{–}Cl} \approx 2.20$ Å and $r_{H\text{–}Cl} = 2.80$ Å, so that it may be taken to correspond to the breaking of the H–Cl bond, essentially corroborating what has already been revealed clearly by the bond order profiles. Figure 7 *b* represents energy profile for the second step of the reaction, in which chloride anion produced in the first step attacks the carbon atom of the H_2COH^+ moiety and formation of C–Cl bond of the product chloromethanol takes place. This step has been simulated by first determining the minimum-energy ground state geometry of H_2COH^+ and bringing in a chloride ion (Cl^-) from a large distance. The net charge of the

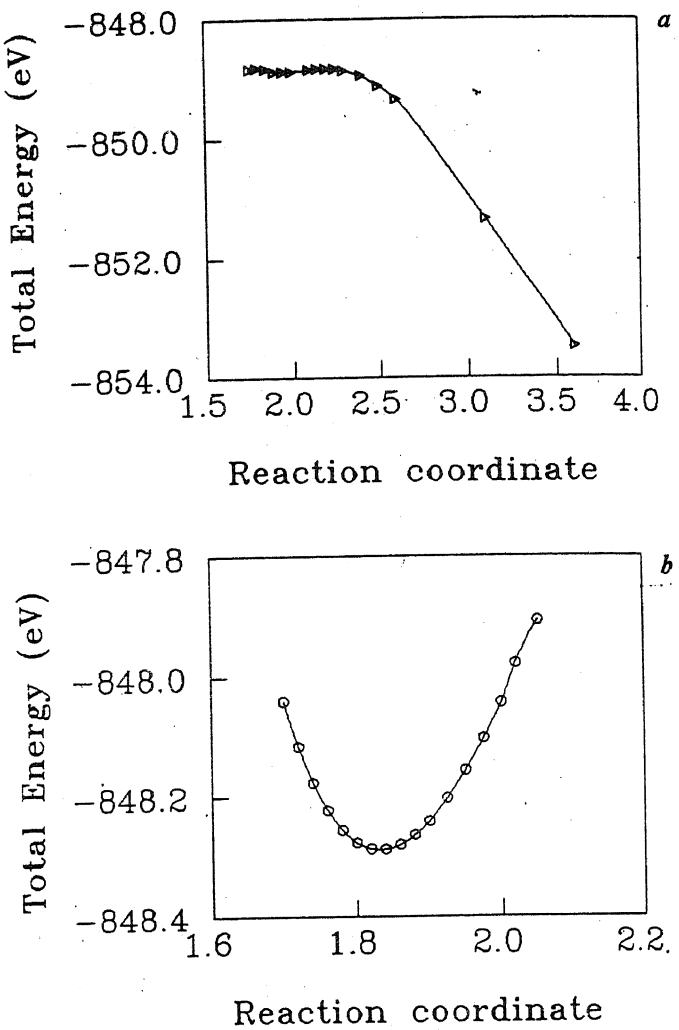

Figure 7. ***a***, Energy profile for the orthogonal approach of HCl to the protonated formaldehyde. The RC essentially represents the C–Cl bond length.

combined system has been kept zero and the entire system has been allowed to relax at each C–Cl distance. The energy decreases monotonically as chloromethanol is formed, without encountering any activation barrier. The first step, viz. the breaking up of HCl into H^+ and Cl^- must, therefore, be the rate-determining step in the addition of HCl^- to H_2COH^+. Relevant kinetic data are, however, unavailable to confirm this scenario experimentally. Similar behaviour has been noted for the addition of H–*X* (*X* = Cl, Br, CN, etc.) to the >C=O moiety, in general. The details will be presented elsewhere.

A BEBO description of the TS in the carbonyl addition reactions

One wonders at this point whether some kind of energy-based description of the carbonyl addition reaction is

feasible within the local model. In other words, how could we transcribe the local picture in terms of the BO profiles of active bonds into a semilocal energy-based picture? A possible recipe that immediately comes to mind is the BEBO model of Johnston and Parr[22, 23] which has been extensively used fairly successfully in studying atom transfer reactions[23–27] of the type $A + BC \rightarrow AB + C$. These reactions basically involve the active bond and the BEBO theory works well. In the present case, however, the basic model needs to be extended. Considering the four active bonds, viz. H–Cl, C–Cl, π(C–O) and O–H, and the corresponding bond orders, the sum of which is constrained to remain conserved along the reaction path, we have the following BEBO function for monitoring the energy changes during the reaction.

$$V = -D^0_{HCl} n^p_{HCl} - D^0_{CCl} n^q_{CCl} - D^0_{\pi(CO)} n^r_{\pi(CO)} - D^0_{OH} n^s_{OH}.$$

In short-hand notation, we may write (with $D^0_{HCl} = D^0_1$,

$D^0_{CCl} = D^0_2$, $D^0_{\pi(CO)} = D^0_3$ and $D^0_{OH} = D^0_4$),

$$V = -D^0_1 n_1^p - D^0_2 n_2^q - D^0_3 n_3^r - D^0_4 n_4^s \qquad (2)$$

where

$$n_1 + n_2 + n_3 + n_4 = 2; \qquad (3)$$

p, q, r and s are, parameters and D^0_{AB}, in general, is the energy of the A–B bond of unit order. Using the active BO sum conservation constraint (3) to eliminate n_4, we have

$$V = -D^0_1 n_1^p - D^0_2 n_2^q - D^0_3 n_3^r - D^0_4 \{2 - (n_1 + n_2 + n_3)\}^s \qquad (4)$$

As the TS, we have

$$\frac{\delta V}{\delta n_1} = \frac{\delta V}{\delta n_2} = \frac{\delta V}{\delta n_3} = 0. \qquad (5)$$

This leads us to a set of three coupled, non-linear equations:

$$\begin{aligned} -p\, D^0_1 n_1^{p-1} + s\, D^0_4\, \{2 - (n_1 + n_2 + n_3)\}^{s-1} &= 0, \\ -q\, D^0_2 n_2^{q-1} + s\, D^0_4\, \{2 - (n_1 + n_2 + n_3)\}^{s-1} &= 0, \\ -r\, D^0_3 n_3^{r-1} + s\, D^0_4\, \{2 - (n_1 + n_2 + n_3)\}^{s-1} &= 0, \end{aligned} \qquad (6)$$

and the BO conservation condition, which demands that

$$n_1 + n_2 + n_3 + n_4 = 2.$$

For $p = q = r = s = 2$, the equations in (6) are linear and can be solved together with $n_4 = 2 - (n_1 + n_2 + n_3)$. For other values of p, q, r, s equations (6) are to be solved iteratively. We have adopted a steepest descent (ascent) type of technique to solve the equations in (6) for $p, q, r, s \neq 2$. However, the TS BOs are found to be only weakly dependent on the p, q, r, s values. Our experience so far indicates that $p = q = r = s = 2$ is a good choice. The BO values obtained by solving equations (6) provide an approximate estimate of the active Bos in the TS. Using Pauling's bond length bond order relationship, $r_{AB} = r^0_{AB} - c^0_{AB} \ln n_{AB}$, the active bond lengths in the TS can also be calculated. The active bond lengths in the TS computed by our EBEBO recipe for (i) $p = q = r = s = 2$, (ii) $p = q = r = s = 3$, (iii) $p = q = r = s = 4$ are reported in Table 1 along with their corresponding values obtained from TS BOs predicted by the global energy-based analysis of the RP at the AM1 level of approximation (standard bond energy data have been used). We must mention here that Pauling's relation assumes that r^0_{AB} corresponds to the length of the A–B bond with BO = 1. However, frequently, the MO calculations predict equilibrium BOs of the A–B bonds that are different from 1. In such cases, one can use a renormalized Pauling bond length bond order relation:

$$r_{AB} = r^0_{AB} - c^0_{AB} \ln(n_{AB} / n^0_{AB}),$$

where n^0_{AB} is the computed bond order at the equilibrium internuclear separation (r^0_{AB}). The most important point to note is that it is the rate of change of BOs of different active bonds along the RP that dominantly determines where the critical point is going to be located. The absolute values of BOs are thus unimportant, rendering renormalized BOs useful and effective. Attempts have been made to improve the bond length bond order relation further by making c_{AB} dependent on the value of r^0_{AB}. Agmon's proposal[27] to take $c^0_{AB} = b_1^{AB} r^0_{AB} - b_2^{AB} r^2_{AB}$ invariably leads to further improvement. But in the present study, we have not used renormalized Pauling's relation or Agmons's improvement on it. When this is done, the agreement between extended BEBO and AM1 results could improve further. The values predicted by the EBEBO model do not fare too badly compared to values obtained from standard energy-based reaction path analysis. The V function of equation (2) can be used to generate energy surface or contour maps either in the BO space or in the internu-

Table 1. Comparison of the active bond lengths in the TS of the gas phase reaction $H_2CO + HCl \rightarrow ClCH_2OH$ computed by the EBEBO model and the AM1 method

Method		r_{HCl} (Å)	r_{CCl} (Å)	r_{OH} (Å)	r_{CO} (Å)

	$p=q=r=s=3$	1.470	1.930	1.162	1.321
	$p=q=r=s=4$	1.465	1.935	1.156	1.323
AM1		1.493	2.000	1.211	1.346

clear distance space. They are very much like the one described already and are, therefore, not reproduced here.

The origin of BO inflexions

We have already seen that only a few bonds are characterized by inflexions in their BO profiles along a given reaction path. That is, a reaction system appears to discriminate between two sets of BO variables, viz., the active and the inactive ones. The active BO variables are characterized by sharp inflexions along the reaction path. Why does it happen? It is clear that the BO inflexions occur over a rather short range. It will not be too speculative to assume, therefore, that forces responsible for the observed behaviour of the active BO profiles during a reaction must be changing rapidly over a rather short range. A clue to the nature of these forces may be hidden in the statistical interpretation of BO.

The chemical bond between a pair of atoms has been traditionally interpreted in terms of a build-up of electron density in the region (the bond region) between the two atoms. Customarily, therefore, the first-order density ρ_1 or quantities related to or obtainable from ρ_1 have been used for describing chemical bonds. A description based on ρ_1 cannot, however, reflect the 'electron pair' character of the most commonly encountered bonds. The second-order density matrix (ρ_2) is a more natural and logical candidate for analysing chemical bonds. The bond order index used by us is due to Mayer[17] and has been shown to be related to the normalization of the diatomic exchange part of the second-order reduced electron density (ρ_2). For a single determinant representable state, ρ_2 is factorizable and the bond order can then be expressed in terms of ρ_1. For such a state it has been shown[28] that

$$B_{AB} = -2\,\{\langle \hat{q}_A \hat{q}_B \rangle - \langle \hat{q}_A \rangle \langle \hat{q}_B \rangle\}, \tag{7}$$

where $\hat{q}_A$ and $\hat{q}_B$ are the LCAO atomic charge density operators for the atoms A and B, respectively, $\hat{q}_A$ and $\hat{q}_B$ are defined by

$$\hat{q}_A = \sum_{\mu \in A} \chi_\mu^+ \phi_\mu^-$$

$$\hat{q}_B = \sum_{\nu \in B} \chi_\nu^+ \phi_\nu^- \tag{8}$$

where χ_μ^+ and ϕ_μ^- are the 'creation' and the corresponding 'true-annihilation' operators corresponding to the spin orbital χ_μ on atom A. χ_μ^+ and ϕ_ν^- are defined accordingly for atom B. These operators satisfy the following relation:

$$\{\chi_\mu^+, \phi_\nu^-\} = \delta_{\mu\nu} \tag{9}$$

It can be shown that the right-hand side of equation (7) is related to the density–density correlation function C_{AB}, defined as

$$C_{AB} = \langle (\hat{q}_A - \langle \hat{q}_A \rangle)(\hat{q}_B - \langle \hat{q}_B \rangle) \rangle, \tag{10}$$

which immediately leads to the identification

$$B_{AB} = -2C_{AB}. \tag{11}$$

Now, $\hat{q}_A - \langle \hat{q}_A \rangle$ measures the fluctuations of electron density on atom A and $\hat{q}_B - \langle \hat{q}_B \rangle$ the same on atom B. C_{AB} in equation (10), therefore, represents the correlation between the fluctuations of the local electron densities on atoms A and B. The BO between two atoms A and B (B_{AB}) which we are monitoring is, therefore, twice C_{AB} (with sign reversed) and measures the correlation between these localized charge fluctuations. The force responsible for this correlation could be Fermi correlation only, as Coulomb correlation is absent in single determinant description of a state. At this stage a comment on the range of Fermi correlation would be in order. It has been shown by Cooper and Paunder[29] that the range of Fermi correlation appears to be somewhat longer than that of Coulomb correlation, contradicting observations made earlier by Boyd and Coulson[30] and also by Benesch and Smith[31]. However, the definition of Fermi correlation used by Cooper and Paunder is different. But even in the study made by Cooper and Paunder, the maximum and the most rapid change in Fermi correlation occurs over a rather short range and so Fermi correlation would abruptly decrease as a bond is stretched beyond the effective range of correlation as the system moves along a given RP. If two atoms are brought closer by such a motion, new correlations develop between charge fluctuations on the atoms involved and we may note an equally abrupt growth of a particular BO. It may be possible to propose another model to explain the observed behaviour of the active BO profiles based on orbital crossings and Walsh diagrams. But we have preferred to adhere to the explanation based on Fermi correlation in order to be consistent with the statistical interpretation. of BO.

Conclusions

Study of quantum chemical BO profiles may be quite helpful in visualizing the course of a chemical reaction. The BO inflexions provide us with a local view of a reaction involving the breaking and making of a number of bonds. We have been able to demonstrate the viability of an EBEBO description of a reaction involving up to a maximum of four active bonds. This brings quite a large variety of reactions under the ambit of our EBEBO model. They include (i) addition to >C=C<, (ii) ABC ↔ BCA isomerization, (iii) cyclopropyl$^+$ ↔ allyl$^+$rearrangement, (iv) reverse 1,3 dipole addition in tetra-aza cyclopentadienes, (v) intramolecular proton transfer in formamidene, (vi) 1,3 H shift, (vii) Cope rearrangement, etc. Many more reactions are being studied to assess the

overall applicability of the local model in studying chemical reactions.

High-temperature tolerance of *Petunia* and *Nicotiana* pollen

G. U. Rao, K. R. Shivanna* and V. K. Sawhney§

Department of Botany, University of Delhi, Delhi 110 007, India
§Department of Biology, University of Saskatchewan, Saskatoon, Saskatchewan, S7N 5E2, Canada

High-temperature tolerance of the pollen of *Petunia hybrida* L. and *Nicotiana sylvestris* L. was investigated by treating dry pollen to temperatures of up to 75°C for 6–48 h and by studying their viability (by fluorochromatic reaction (FCR) test), vigour (by a semi-vivo method), and their ability to set fruits and seeds. In *Petunia*, temperatures of up to 60°C for 48 h did not affect pollen viability, vigour and their fruit- and seed-setting ability. A temperature of 75°C for 24 h reduced pollen viability and vigour, but fruit- and seed-setting ability existed. However, a 75°C exposure for 48 h proved lethal for *Petunia* pollen. In *Nicotiana*, pollen exposed to temperatures of up to 75°C for 6–12 h were able to set seed. With a longer exposure the majority of pollen were FCR-positive, but they were unable to set seed. These results show that pollen grains of *Petunia* and *Nicotiana* can withstand exposures of temperatures as high as 75°C and retain pollen function. This study also indicates that FCR test may not reflect true viability in pollen subjected to extreme stresses.

*For correspondence.

IN general, the activity of most metabolizing cells and tissues is best maintained within a moderate temperature range. Extreme low or high temperatures are detrimental to the activity or survival of most cells. Many plant cells respond to heat stress by the synthesis of heat shock proteins[1]. However, desiccated systems such as seeds can withstand a high degree of temperature range[2]. Pollen grains are also desiccated systems and show many physiological similarities to seeds[3]. The tolerance of pollen grains to low temperatures is well documented in studies on their storage under low and ultralow temperatures[4,5]. In contrast, much less is known of the high-temperature tolerance of pollen grains.

Earlier studies on high-temperature stress of pollen were restricted to examining the viability or *in vitro* germinability of treated pollen[6,7]. However, the effects of high temperatures on pollen function, i.e. pollen vigour and the ability of stressed pollen to induce fruit and seed set were not examined. Elsewhere, we have shown that *Brassica juncea* pollen exposed to 75°C for 24 h failed to germinate on the stigma and were unable to induce seed set[8].

In this paper we report on the viability, vigour and fruit- and seed-setting ability of *Petunia hybrida* and *Nicotiana sylvestris* pollen subjected to high temperatures of 45–75°C.

Materials and methods

Plants of *P. hybrida* L. grown under field conditions and of *N. sylvestris* L. grown under glasshouse conditions were used for investigations. Pollen grains from freshly dehisced anthers were uniformly spread on microslides, kept in dry Petri plates, and exposed to different temperatures: laboratory (22 ± 2°C), 45 ± 2°C, 60 ± 2C° and 75 ± 2°C, for various durations. After the treatment, pollen samples were tested for viability, vigour and their ability to set fruits and seeds.

Pollen viability was assessed by the fluorochromatic reaction (FCR) test as described by Heslop-Harrison and Heslop-Harrison[9]. Pollen grains were either used directly after the treatment or after prehydration of 30 min under high humidity by placing the samples in Petri plates lined with moist filter paper. Each treatment was repeated at least two times with two replicates each time. For each replicate at least 300 pollen grains were scored for the FCR test. Test of significance was performed by the group comparison test[10].

Pollen vigour was tested by the semi-vivo method[11,12]. Flower buds were emasculated before anthesis and pollinated on the day of anthesis with pollen exposed to different temperatures. Three hours after pollination, 1.0 cm of the style along with the stigma was cut with a sharp blade, and the cut end implanted in the pollen germination medium (sucrose 10% + boric acid 100 mg/l + calcium nitrate 300 mg/l + 0.8% agar) set in Petri plates. The cut ends of styles were observed under a stereomicroscope at regular intervals to record the time of pollen tube emergence and the number of tubes emerged. In one experiment, pollen tubes emerging from cut ends of styles were stained with DAPI (4′,6-diamidino-2-phenylindole), a DNA fluorochrome[13], to examine the division of the generative cell.

In vivo pollen germination and pollen tube growth was checked in pistils after 3–48 h of pollination. Pistils were fixed in FAA (formalin:glacial acetic acid: 70% ethanol; 5:5:90 v/v) for 24 h, cleared in 4 N NaOH overnight, and mounted in a drop of 0.005% decolourized aniline blue (Gurr) (in 0.05 M Na_2HPO_4 at pH 8.2). Pollen tube growth was examined in a Zeiss/Nikon fluorescent microscope.

Moisture loss in pollen grains was determined in 100 mg pollen samples. Pollen grains were placed in preweighed aluminium cups, and the samples maintained at different temperature conditions. After 24 and 48 h, pollen grains were weighed and the loss in weight was recorded as the loss of moisture content.

Pollen grains from all treatments were used for pollination of emasculated and bagged flowers to determine their ability to set fruit and seed. The flowers were rebagged after pollination. The mature fruits were harvested and the fruit size (diameter), weight of seeds per fruit, and the weight of 100 seeds of each treatment were recorded.

Results

Petunia hybrida

Moisture loss

There was no detectable loss of water in pollen samples maintained under laboratory conditions for 24 or 48 h, in comparison to fresh pollen (control). However, pollen exposed to 45 or 60°C temperature for 24 or 48 h resulted in approximately 5% water loss. An exposure of 75°C for 24 or 48 h caused an 8% water loss in pollen, and there was no further loss in pollen exposed for 48 h.

Pollen viability

Pollen viability was expressed as percentage FCR response. Exposures of 60°C for 24 h (Figure 1 *a*) and 45°C for 48 h (Figure 1 *b*) reduced the FCR values in comparison to fresh pollen (control) or lab conditions. However, 30 min prehydration of pollen restored the FCR score to the control level. Temperatures of 75°C for 24 h (Figure 1 *a*) and 60°C for 48 h (Figure 1 *b*) reduced significantly the percentage FCR response, and prehydration at these temperatures was not effective in restoring the FCR score. Pollen grains exposed to 75°C

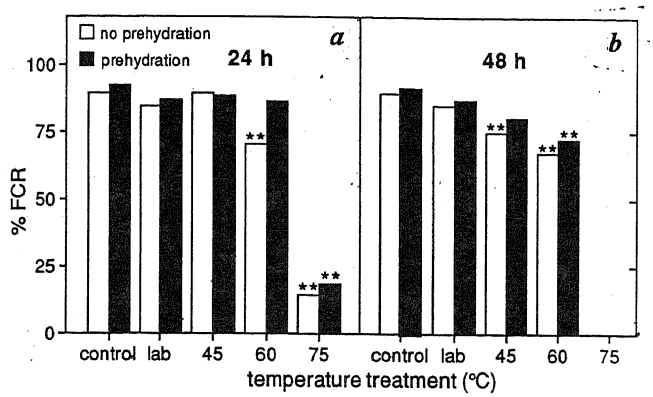

Figure 1. FCR response of *P. hybrida* pollen treated for 24 h (*a*) and 48 h (*b*) at different temperatures tested directly and after 30 min of prehydration. The values indicated by (**) are significantly different from the control (fresh pollen) at $P < 0.01$ level.

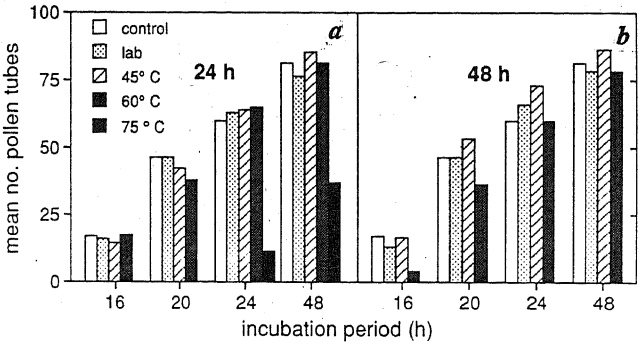

Figure 2. Mean number of pollen tubes ot *P. hybrida* emerging from semi-vivo implanted pistils pollinated with pollen exposed to different temperatures for 24 h (*a*) and 48 h (*b*), and incubated for 16–48 h. Pollen tube number was counted up to 100; it was not possible to count accurately beyond 100.

for 48 h failed to show the typical FCR fluorescence (Figure 1 *b*); they mostly showed dull fluorescence, although strong background fluorescence was observed in the medium.

Pollen vigour

The vigour of pollen grains, i.e. the time taken by pollen tube to travel through the style, was analysed using the semi-vivo method. The mean number of pollen tubes that emerged from the cut end of pistil varied depending on the temperature and duration of the treatment. In pollen exposed to 75°C for 24 h there was a marked delay in pollen tube emergence; no pollen tubes emerged for 20 h, there was some emergence by 24 h, and by 48 h the number of tubes emerged was less than one-half of that in the other treatments (Figure 2 *a*). In pollen grains exposed to 60°C for 48 h, there was reduction in the number of tubes emerging during the first 20 h; however, by 24 h the number was comparable to the control (Figure 2 *b*). There was no pollen tube emergence in pollen grains exposed to 75°C for 48 h (Figure 2 *b*).

Pollen tubes that emerged from styles were stained with DAPI to check the presence of sperm cells. In the control as well as in the treatments where pollen tubes emerged, two sperm cells were observed.

Pollen tube growth studies performed *in vivo* were in agreement with those of the semi-vivo method. The pistils pollinated with control pollen and with pollen treated for up to 60°C for 24 h showed high germination in 3 h, and a large number of pollen tubes reached the ovary in 24 h. However, pistils pollinated with pollen exposed to 75°C for 24 h showed very few germinating pollen in 3 h, and by 48 h only a few pollen tubes had reached the ovary. Pollen tubes of 75°C-treated pollen had a thick wall and the tube growth was not uniform compared to other treatments.

Fruit- and seed-setting ability

The fruit- and seed-setting ability of high-temperature-treated pollen showed that pollen grains treated for up to 60°C for 24 or 48 h were as effective (90% fruit set) as fresh pollen. Also, the size (diameter) of fruits was not affected in these treatments (Figure 3 *a*). Pollen exposed to 75°C for 24 h were also effective in inducing fruit set although fruit-set was observed in only 70% of pollinated pistils, and the fruit size was also reduced (Figure 3 *a*). The weight of seeds produced in a fruit was, interestingly, more in 45°C (both 24 and 48 h treatments) and in 60°C for 24 h, in comparison to the control (Figure 3 *b*), but it was reduced in the 75°C treatment (Figure 3 *b*). There was no difference in the weight of 100 seeds produced in most treatments. However, in 75°C (24 h) treatment, there was an increase in the weight of 100 seeds (Figure 3 *c*).

In one experiment 45 and 60°C treatments were extended to 5 days. There was no apparent effect on the fruit- and seed-setting ability of 45°C-treated pollen. However, the 60°C treatment reduced both the fruit size and the seed weight per fruit.

Nicotiana sylvestris

Preliminary experiments with *N. sylvestris* pollen showed that high temperatures of up to 60°C for 48 h had no adverse effect on pollen function. Therefore, studies on *Nicotiana* were largely confined to 75°C treatments for 6–48 h.

The pollen viability tests showed that over 50% of pollen exposed to 75°C for 24 h, were FCR-positive, in comparison to approximately 20% for *Petunia*. Exposures longer than 24 h were, however, lethal to *Nicotiana* pollen.

Pollen vigour tests by the semi-vivo method showed that in control more than 100 pollen tubes emerged in 20 h. In contrast, pollen exposed to 75°C for 12 h took

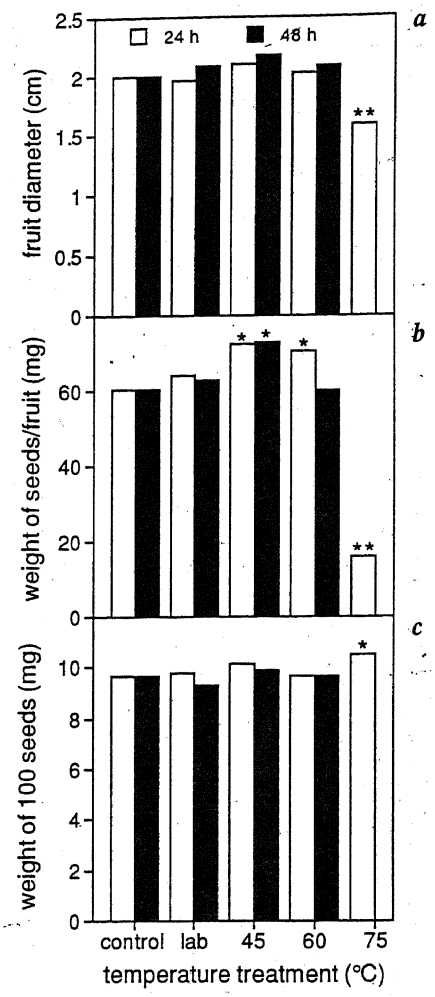

Figure 3. Fruit and seed characteristics obtained after pollination with pollen samples of *P. hybrida* exposed to different temperatures for 24 and 48 h: (*a*) fruit diameter; (*b*) average weight of seeds per fruit; and (*c*) average weight of 100 seeds. (*) and (**) are significant at $P < 0.05$ and $P < 0.01$ probability level, respectively, as compared to control (fresh pollen).

48–50 h for tube emergence and in those treated for 24 h there was no tube emergence even by 50 h. Fluorescence studies of pistils 50 h after pollination with pollen treated to 75°C for 24 h revealed germination of only 50–100 pollen grains on the stigma. Of these, only about 20–30 tubes entered the style and 5–10 tubes approached the cut ends of the style.

Fruit and seed sets were obtained with pollen treated at 75°C for 6 h and were comparable to the control (fresh pollen). However, pollen treated for 12 h yielded fruits in only 60% of pollinated flowers and the size of fruits and the number of seeds per fruit were markedly reduced (data not given). Pollen samples exposed to 75°C for 24 and 48 h failed to set fruit and seed.

Discussion

The results presented here have shown that pollen grains of *Petunia hybrida* and *Nicotiana sylvestris* are able to withstand a high temperature stress of up to 75°C, albeit for short periods, and retain not only the viability but also the ability to set fruits and seeds. However, the 75°C treatment reduces pollen vigour; treated pollen take much longer time to germinate and for the pollen tubes to reach the ovary. The reduction in the size of fruits and weight of seeds/fruit by 75°C (24 h) treatment in *Petunia* may be attributed to the fewer number of pollen tubes reaching the ovary before the ovules lose receptivity. However, there was a small increase in the weight of 100 seeds for this treatment. This may be explained on the basis of reduced competition among the fertilized ovules for nutrients.

FCR test is generally considered as the best available method to assess pollen viability (ability to effect fertilization)[14,15]. Our earlier studies[11] on pollen subjected to moderate stresses highlighted the limitation of the FCR test in assessing pollen vigour although it did reflect viability. Our studies on heat-treated pollen of *Brassica*[8] indicated that the extent of retention of fluorescence may give a better indication of pollen function than initial fluorescence. Present studies clearly show that the FCR test does not necessarily reflect true viability or vigour in pollen subjected to extreme stresses. Over 50% of *Nicotiana* pollen treated at 75°C for 24 h, were FCR-positive, but failed to effect fertilization. The pistils pollinated with such pollen showed germination of only 50–100 pollen on the stigma and growth of only 5–10 tubes in the style even after 50 h of pollination. Thus, the result of the FCR test on stressed pollen needs to be used with caution.

Previous studies on high-temperature tolerance of pollen were limited to a few taxa and were confined largely to *in vitro* germination tests. Pollen of lily, apple and rose showed[6] 50% germinability when exposed to 70°C for 4–8 h. A small proportion of *Eucalyptus rhodantha* pollen retained[7] *in vitro* germinability after exposure to 70°C for 24 h.

Our earlier studies on *B. juncea*[8] showed that exposure of pollen to 60°C for up to 24 h did not affect pollen viability and their ability to set fruits and seeds. However, pollen exposure to 75°C even for 4 h failed to germinate either *in vitro* or *in vivo*. The pollen of lily, apple and rose[6], *Eucalyptus*[7], and *Petunia* and *Nicotiana* (present studies) are all two-celled pollen systems, and seem to be more tolerant to high-temperature stress than the pollen of *B. juncea*[8], a three-celled system. Although high-temperature tolerance of no other three-celled pollen system, to our knowledge, has been investigated, this difference is in line with a range of other physiological differences between two- and three-celled pollen systems[16–19].

Heat tolerance of *E. rhodantha* pollen has been suggested to be an adaptation to the harsh semi-arid conditions prevailing in the natural habitat of the species (Western Australia), in which pollen grains are likely to remain exposed to prolonged heat and desiccation before pollination[7]. The authors suggested that similar heat tolerance is likely to be present in other species adapted for the same type of harsh environment as of *E. rhodantha*. The present investigation on *Petunia* and *Nicotiana*, and the earlier studies on lily, apple and rose[6], the species which grow under moderate or temperate conditions, have shown that high-temperature tolerance in all these species is comparable to that of *E rhodantha*. Thus, pollen grains in general and two-celled pollen in particular shown high-temperature tolerance, which is likely to be related to low moisture level present in most of the pollen systems. Small differences in the degree of tolerance between species may reflect the differences in the ability of the pollen protoplasts and membranes to withstand extreme desiccation associated with high temperatures.

Studies on pollen grains of some of the cereals such as wheat and maize also show that a low moisture level is an essential requirement for high-temperature tolerance. Pollen of cereals, unlike the pollen of a majority of taxa, are shed under more hydrated conditions[20]; such pollen lose their ability to effect fertilization even under moderately high temperature stress of 40°C for 4 h (ref. 21).

Extensive studies have been carried out on the tolerance of actively metabolizing organisms at supraoptimal temperatures[2,22]. Evidence indicates that the accumulation of metabolites such as proline and betain may provide thermal protection to several enzymes[23]. It is suggested that proline might stabilize protein configuration by maintaining hydration shells around the molecules. Pollen grains in general are rich in proline[4]. In *Petunia* pollen, free proline accounts for 2.6% of dry weight[24]. Zhang and Croes[25] reported that proline protected germination and metabolic function of *Lilium* pollen from unfavourably high and low temperatures. Further studies are, however, needed to understand the biochemical basis of thermotolerance in pollen grains. It has been shown that some heat shock proteins are expressed in developing seeds[26] and pollen grains[27]. These may also play a role in heat tolerance of desiccated pollen grains.

Solid State and Structural Chemistry Unit, *Department of Metallurgy, †Department of Physics, Indian Institute of Science, Bangalore 560 012, India

Over 80% negative giant magnetoresistance (GMR) is observed in the self doped $La_{0.7}Mn_{3-\delta}$ oxide thin film in a magnetic field of 6 Tesla at 225 K. $La_{0.7}Mn_{3-\delta}$ (magnetic)/$La_{0.85}MnO_3$ (nonmagnetic) oxide multilayers showed a higher GMR effect up to 89% at 225 K compared to the single $La_{0.7}Mn_{3-\delta}$ oxide films. The results demonstrate that the large GMR observed in the doped manganates is inherent to the oxide material whereas the enhanced GMR to the extent of 6–10% in the multilayers compared to the parent magnetic film is due to the coupling of magnetoresistance in the parallel magnetic oxide layers separated by nonmagnetic oxide layers as in $(Fe/Cr)_n$ multilayer metal film.

GIANT magnetoresistance (GMR) is defined by the ratio $(R_H - R_0)/R_0$, where R_H and R_0 are the resistances in presence and absence of a magnetic field. GMR effect was first observed in the single crystals of $La_{0.62}Pb_{0.38}MnO_3$[1]. Over 50% negative GMR was reported by Baibich *et al.*[2] in $(Fe/Cr)_n$ magnetic/nonmagnetic metal multilayers. Presently, there is a tremendous interest in the study of GMR effect because, large variation in the resistance in the presence and absence of a magnetic field can have direct application as the 'readhead' for magnetic recording systems. Observation of over 50% GMR in the epitaxial thin films of $La_{0.67}Ba_{0.33}MnO_3$ oxide thin films[3] at 300 K triggered the interest on this subject. $La_{1-x}M_xMnO_3$ (M = Ca, Sr, Pb)[4–6] thin films showed large GMR effects.

$LaMnO_3$ is an antiferromagnetic oxide possessing orthorhombic structure. It is possible to synthesize lanthanum deficient $La_{1-x}MnO_3$ with 18–20% Mn ions in the 4+ state. These compounds crystallize in a rhombohedral structure and exhibit a paramagnetic to ferromagnetic transition, coupled with insulator to metal transition, when samples are cooled below 300 K. We have recently observed over 80% GMR in 5% Ag-doped $La_{0.7}MnO_{3-\delta}$ thin films at 220 K.

Although large GMR effect is observed in the doped manganates, it is not yet clear whether the mechanism of GMR operating in these oxide films is the same as in the $(Fe/Cr)_n$ multilayer metal films. In order to gain further insight into the mechanism of GMR we considered it worthwhile to fabricate $La_{0.7}MnO_{3-\delta}$ (magnetic)/$La_{0.85}MnO_{3-\delta}$ (nonmagnetic) oxide multilayers since they are structurally compatible. We report, in this paper, the first fabrication of magnetic/nonmagnetic oxide multilayers by pulsed laser deposition and show an enhanced GMR effect in the oxide multilayers compared to the parent $La_{0.7}MnO_{3-\delta}$ magnetic oxide thin films.

Bulk samples of nominal composition $La_{0.7}MnO_{3-\delta}$ and $La_{0.85}MnO_{3-\delta}$ were prepared by heating stoichiometric amounts of La_2O_3 and $MnCO_3$ at 1050°C in air. These oxides in bulk did show ferromagnetic transition at 220 and 240 K, respectively. However, when the films of these materials were made by pulsed laser deposition, they did not show metallic transition. The discrepancy in the properties of the bulk solid and the thin films was attributed to oxygen deficiency. In order to overcome the oxygen out-diffusion in the thin films, 5% Ag_2O was added to the $La_{0.7}MnO_{3-\delta}$ which was used as the laser target. Silver is known to enhance epitaxial growth of $YBa_2Cu_3O_{7-\delta}$ films in addition to bringing in extra oxygen during pulsed laser deposition[8]. Ag ion is not known to substitute for any ion in $La_{1-x}MnO_3$. The films grown with 5% Ag_2O showed metallic conductivity below 220 K. Films made out of $La_{0.85}MnO_{3-\delta}$ pellet (without addition of Ag_2O) showed a semiconducting behaviour which is employed as the nonmagnetic oxide layer in this study.

Thin films of $La_{0.7}MnO_{3-\delta}$ with 5% Ag_2O (Ag-MNO) and $La_{0.85}MnO_{3-\delta}$ (LMO) without Ag_2O were deposited separately on $LaAlO_3$ (1 0 0) substrate by pulsed laser deposition at 720°C in 300 mtorr O_2. Superlattices of $(Ag–LMO/LMO)_{20}$ were also deposited on $LaAlO_3$ (1 0 0) substrate. Ag–LMO and LMO were deposited alternatively using a multitarget holder with 60 and 12 laser pulses, respectively, at a (KrF 248 nm) laser pulse energy density of 2 J/cm^2. From the thicknesses of Ag–LMO and LMO films prepared separately, estimated layer thicknesses in the multilayer are 100 Å and 20 Å, respectively, for Ag–LMO and LMO. X-ray diffraction pattern of the multilayer film given in Figure 1 shows highly textured growth in (1 0 0) direction on $LaAlO_3$ with pseudocubic $a = 3.88$ Å agreeing well with the observed a parameter of the bulk $La_{1-x}MnO_{3-\delta}$. Ag–LMO as well as LMO films also showed a similar oriented growth. Superlattice reflections were not seen in the form of satellite peaks adjacent to (1 0 0) or (2 0 0) reflections of LMO possibly because La^{3+} and oxygen defects are randomly distributed.

Resistivity measured by four point probe method at zero field for a 2500 Å thick epitaxial film of Ag–LMO, LMO and $(Ag–LMO/LMO)_{20}$ multilayer are shown in Figure 2. Sharp change in the slope is observed in the ρ vs T curve, for the Ag–LMO and the multilayer films. The LMO film showed a semiconducting behaviour. Room temperature resistivity of Ag–LMO and LMO

‡For correspondence.

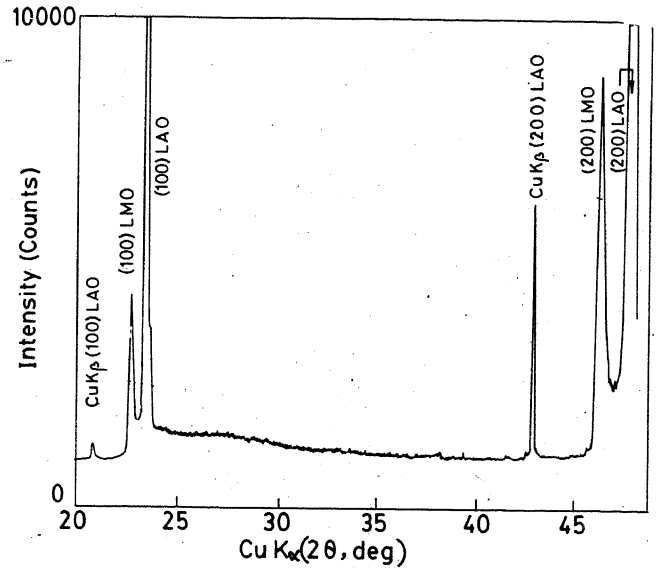

Figure 1. X-ray diffraction pattern of (Ag–$La_{0.7}MnO_{3-\delta}$/$La_{0.85}MnO_{3-\delta}$)$_{20}$ multilayer thin film.

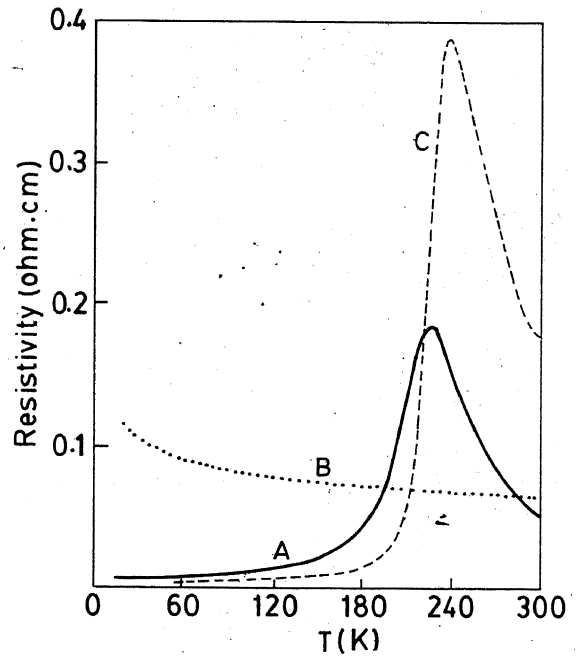

Figure 2. Resistivity vs temperature plots of (A) Ag–$La_{0.7}MnO_{3-\delta}$ (B) $La_{0.85}MnO_{3-\delta}$ and (C) (Ag–$La_{0.7}MnO_{3-\delta}$/$La_{0.85}MnO_{3-\delta}$)$_{20}$ multilayer films on $LaAlO_3$ (100).

films were in the range of 60–70 mΩ cm. Metal to insulator transition temperature, T_c in the multilayer film is about 235 K and that in the single Ag– $La_{0.7}MnO_{3-\delta}$ film is 225 K. The higher resistivity of the multilayer film above 220 K can be accounted for in terms of addition of resistances of the Ag–$La_{0.7}MnO_{3-\delta}$ and $La_{0.85}MnO_{3-\delta}$ films in series. Below the transition temperature the metallic resistivity of Ag–LMO dominates

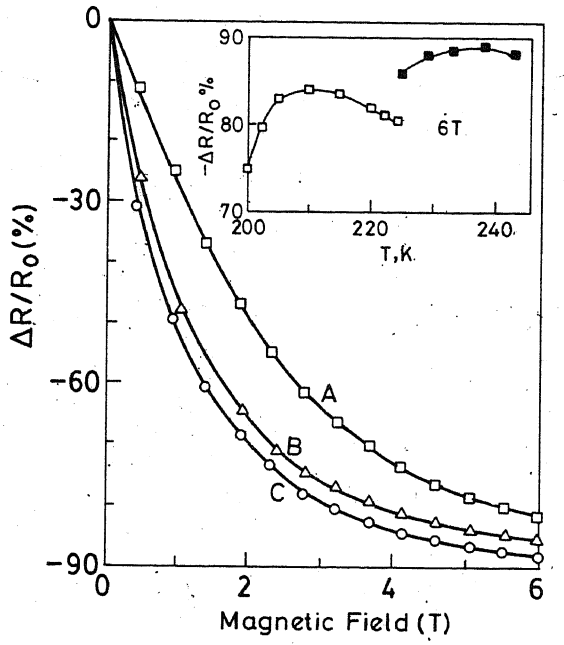

Figure 3. Variation of magnetoresistance $\Delta R/R_0$ as a function of magnetic field at 225 K for (A) Ag–$La_{0.7}MnO_{3-\delta}$ film with H perpendicular to the film; (B) (Ag–$La_{0.7}MnO_{3-\delta}$/$La_{0.85}MnO_{3-\delta}$; (C) Film in B parallel to the field H. Inset shows variation in GMR with temperature at 6 T for Ag–LMO film (□) and multilayer film (■)

and resistivity of the film is essentially a parallel combination of the two oxide layers.

In Figure 3 are shown the percentage $\Delta R/R_0$ vs magnetic field, plots for the parent Ag–LMO (A) and (Ag–LMO/LMO)$_{20}$ (B) multilayer films at 225 K. The measurements were made with H parallel and perpendicular to the film surface. In the case of the parent Ag–LMO film, about 80% GMR is obtained at 6T and there was no difference in the GMR values whether H was parallel or perpendicular to the film surface. A similar isotropic GMR effect is reported in all the doped lanthanum manganate films[3–6]. An enhanced GMR effect is observed in the (Ag–LMO/LMO)$_{20}$ film by about 6–10% compared to the parent Ag–LMO. Further, when the H was parallel to the surface, GMR value was higher by 3% compared to when H was perpendicular (curve C). Anisotropic GMR effect was observed in the case of $(Fe/Cr)_n$ metallic multilayer film as well. In the inset, GMR vs T plots for the parent and multilayer films measured at 6 T parallel to the film surface is shown demonstrating the enhanced GMR effect in the multilayer films.

The pseudocubic cell of doped manganates in general consists of MnO_2 magnetic layers separated by a nonmagnetic La–O or La(M)–O (M = divalent ion) oxide layers. As the temperature is decreased, ferromagnetic order sets in the MnO_2 layer due to Zener double exchange mechanism of electron transfer in the Mn^{3+}–O–Mn^{4+} chains in all the three directions and resistivity

decreases[9,10]. Alternatively, when a magnetic field is applied externally at a given temperature, ferromagnetic order is induced in the MnO_2 layers leading to a decrease in resistance. In the self doped $La_{0.7}MnO_{3-\delta}$, the pronounced GMR effect is attributed to La^{3+} and O^{2-} vacancies which form the scattering centers for the conducting electrons, thereby increasing the resistivity. Applied magnetic field seems to provide sufficient activation energy for the alignment of spins to overcome the additional scattering of conducting electrons.

In the case of multilayer, we propose that there are two factors contributing to the total GMR. The first one is the decrease in the resistances of individual magnetic oxide layers as in the single Ag–LMO film. This value is about 80% at 6T. The second factor is the parallel combination of resistances of the individual magnetic oxide layers separated by the non-magnetic spacer layer. This is about 8–10% thus giving 89% GMR at 6T in the $(Ag–LMO/LMO)_{20}$. The secondary contribution seems to arise from the spin dependent scattering of the conduction electrons at the interface between the ferromagnetic oxide and the nonmagnetic oxide. The order of magnitude of the secondary contribution to the total GMR is about 8–10% which is about the same as that of magnetic/nonmagnetic metal multilayers such as $(Co/Cu)_n$.

In conclusion, we have shown for the first time, a superlattice sequence of magnetic/nonmagnetic oxide multilayer, mimicking the $(Fe/Cr)_n$ superlattices, showing an enhanced GMR compared to the GMR observed in the parent magnetic oxide thin films. We have also shown an anisotropic behaviour in the multilayer oxide films compared to an isotropic behaviour in lanthanum manganate thin films,

Physiobiochemical aspects of development of hardseededness in *Albizia lebbek*

R. C. Uniyal and A. R. Nautiyal

High Altitude Plant Physiology Research Centre,
HNB Garhwal University, Srinagar Garhwal 246 174, India

Seeds of *Albizia lebbek* exhibit dormancy due to hard seeded coat. Seed development was studied in this species to determine whether the induction of hardseededness precedes or succeeds the attainment of physiological maturity and also whether the hardseededness is an inherent character of the seed or can be escaped by harvesting seeds before its induction. The seeds attained physiological maturity at approximately 230 DAA accompanied by acquisition of germinability. This phase was characterized by rapid accumulation of starch, soluble carbohydrates, proteins and chlorophyll. The onset of hardseededness followed, proceeding gradually until 270 DAA and then increased rapidly. While the soluble carbohydrates and chlorophyll contents declined during this period, the starch and proteins showed an increase. Hardseededness in these seeds seems to be their inherent character as it not only occurred in seeds attached to the parent plant but also in seeds in storage, although considerably delayed in the latter case.

DELAYED germination of seeds due to hard seed coats is a common characteristic of many leguminous seeds. *Albizia lebbek* (L.) Willd. is one such multipurpose tree species in which hardseededness poses a practical problem for germination of its seeds. The occurrence of hardseededness in some seeds indicates that the prevailing environment during seed development plays a significant role in developing a hard seed coat[1–3]. However, information is lacking on the germinability and performance of seeds harvested prior to induction of hardseededness. Thus, the present investigation was undertaken to determine whether seeds attain germinability before the induction of hardseededness, and if so, whether hardseededness could be escaped by harvesting seeds before its induction.

Table 1. The physiobiochemical changes and germination in the seeds of *A. lebbek* during development (Mean ± SE)

Stage (DAA)	Pod fr wt (g)	Seed wt. (mg) Fresh	Seed wt. (mg) Dry	Seed MC	Chl a+b mg/g fresh weight	Sol.sug mg/g fresh weight	Starch mg/g fresh weight	Sol. prot. mg/g fresh weight	Percentage germination after storage (months)* 0	1	2	3	4	5

DAA – Days after anthesis.
ND – Not determined due to accidental loss of seeds.
* – These data represent percentage germination without any treatment. After hot water treatment the germination ranged from 90 to 100%.

The study was undertaken in two subsequent years 1991–1992 and 1992–1993. Careful monitoring of pod and seed development was done beginning at the full-bloom stage and commencing 150 days after anthesis (DAA) when seeds were still minute in size but yet easily separable from the pod. The observations on the development of pod and seeds of *A. lebbek* revealed that development of seeds was delayed until pods had attained almost full growth, after which seeds began to develop rapidly. It required 150 days from anthesis for pods to reach this stage. Thus, pods of *A. lebbek* were collected from a natural stand at Srinagar Garhwal (550 m altitude) at 20-day intervals beginning 150 DAA and continuing until 310 DAA when pods reached a dry stage and started shedding. Stages were identified as M_1, M_2, M_3 310 DAA. Following each harvest, ten randomly chosen pods were analysed for their weight, size and colour. Fifty pods were dissected to liberate their seeds, which were mixed together and analysed for their weight, moisture content, biochemical analyses, germination and storability.

The moisture content of ten randomly chosen seeds was determined by drying them at 80°C for 48 h in an electric oven, after first determining their fresh weight, and calculating by the formulae given by Evans[4]. For germination, seeds were kept in three sets, each set containing 50 seeds, on the top of Whatman no. 1 filter paper in Petri dishes of 9 cm diameter and moistened daily with distilled water. Petri dishes were placed at room temperature, which varied between 17 and 24°C during the course of study. Daily observations were made for monitoring the germination (radical emergence) up to 30 days after sowing. To test the germinability of hard seeds, the seeds were soaked in hot water before placing them for germination. To study the changes in composition during maturation, the contents of chlorophyll, soluble sugars, starch and soluble proteins in freshly harvested seeds were determined. For chlorophyll determination Holm's[5] method, for carbohydrates the Anthrone method[6] and for soluble protein estimation the method given by Lowry *et al.*[7] were used.

As mentioned above, development of seed was delayed until pods attained almost full growth, which took 150 days after anthesis. Pod growth continued for an additional 40 days (M_3 stage) and subsequently ceased, after which the fresh weight of pods started declining (Table 1). In contrast, the fresh weight and dry weight of seeds increased progressively for 60 days until 210 DAA (M_4 stage), and subsequently a significant decline in seed fresh weight was recorded, which reached less than 50% of its maximum fresh weight at the time of seed shedding. However, after reaching a maximum on 210 DAA, the dry weight decreased slightly, which was not statistically significant except in the last stage. The moisture content of the seed started declining 170 DAA, first slowly and then very rapidly. Moisture content declined to 50% at 230 DAA, finally reaching 14.8% on 310 DAA. Maximum pod length and breadth were attained between 170 and 190 DAA; thereafter, while the length remained static, the breadth displayed gradual attenuation. The pod, however, exhibited a series of colour changes from green up to 230 DAA,

Table 2. Coefficient of correlation between various parameters studied during seed development in *A. lebbek* ($n = 10$ in each case)

	Days after anthesis	Seed dry weight
Starch	0.792****	0.969*****
Sugar	0.650**	0.624*
Protein	0.985*****	0.822****

Levels of significance.
$p = 0.1$*, $p = 0.05$**, $p = 0.01$****, $p = 0.001$*****.

then greenish yellow between 230 and 270 DAA, and finally a dark yellow.

The chlorophyll content was 0.283 mg g^{-1} until 210 DAA. Thereafter, it declined to 0.030 mg g^{-1} fr. wt at the time of pod shedding. Contrary to this, the soluble sugar content, starch and soluble proteins increased during seed development. Statistical analysis of the data shows a positive and highly significant correlation in biochemical constituents and seed development (Table 2). While a decrease was observed for carbohydrates at the maximum seed weight stage, soluble protein content continued to increase until the second last stage. During this period of seed development, a remarkable increase in all biochemical constituents was recorded during the early phase, i.e. between 150 and 230 DAA. It was during this period that seed attained maximum fresh and dry weight. Starch, soluble carbohydrates and soluble proteins all had a positive correlation with seed dry weight, which was highly significant in the case of starch ($p = 0.001$) and proteins ($p = 0.01$), indicating that these are the major contributors for the seed dry weight. The increasing trend of soluble sugars, starch and soluble proteins during seed maturation showed the relationship between the synthesis of nitrogenous compounds, i.e., proteins, during maturation (important in the formation of organelles, cytosol and membranes) and the metabolites that participate in vital processes in the seeds, as reported by Chamma *et al.*[8].

The developing seeds attained germinability around 190 DAA as 80% germination was obtained in seeds at this stage without exhibiting any hardseededness. By 210 DAA all seeds had acquired the ability to germinate as 100% germination was recorded at this stage (Table 1). This was the stage when the mean dry weight of the seed was also maximum. Physiological maturity in angiosperms has generally been designated as completion of organic accumulation within the seed as reflected by no further increase in its dry weight[9, 10]. Thus, in the present study it seems that seeds of *A. lebbek* attained physiological maturity around 210 DAA, because seed dry weight was maximum and germination was 100%, but the ability to germinate even prior to this stage indicates that acquisition of germinability preceded attainment of physiological maturity in this case, as increase in seed dry weight between M_3 and M_4 stages was statistically significant. However, this is not an exception, as in some other legumes also the seeds developed the ability to germinate even prior to the attainment of maximum dry weight[11]. Subsequent to 210 DAA, a gradual decline in percentage germination was recorded which was remarkable during the final stage between 290 and 310 DAA, when a 65% decline was recorded in the germinability of seeds and thus the seeds seemed to have attained complete hardseededness at this stage as no germination was recorded without scarification. Thus, there is a clear cut indication that hardseededness in *A. lebbek* is induced after attainment of physiological maturity, characterized by maximum seed dry weight, the M_4 stage. In spite of the onset of hardseededness after the M_4 stage, a high percentage of seeds still exhibited germination ranging from 95% at M_5 stage to 85% at M_7 stage without any scarification. This may be due to the slow progress in development of hardseededness during this period; therefore, seeds can be harvested at these stages.

Seeds harvested at M_4 stage could not be stored viably but those from subsequent stages not only stored well but also exhibited an interesting pattern of germination during storage. Seeds stored at room temperature for five months and tested for their germinability at monthly intervals showed a gradual decline in their percentage of germination with their age in storage, not because of the loss of viability but due to development of hardseededness, which was evidenced by their germination after hot water treatment. This decline in germination was faster in the seeds harvested at advanced stages (e.g. M_8 or M_7 stage) than at an early stage (M_5 stage), as evident by the data in Table 1. After four months in storage, while percentage germination declined only by 20% as compared to freshly harvested seeds at M_5 stage, in case of M_7 and M_8 stages the decline was 30 and 87%. By six months all seeds in storage had developed hardseededness and none germinated without scarification. Thus, hardseededness seems to be an inherent character of these seeds and is not related to its attachment with the parent plant as the process of development of hardseededness continued even after the seed had been detached from the plant and kept in storage. Adams and Rinne[12] have also reported for *Glycine max* that the maturation is an inherent function of the seed, the completion of which does not depend on the association of the seed with the parent plant. Interestingly, here the development of hardseededness was faster when the seeds were attached to plant than in storage.

The evaluation of parameters that allow the visual identification of physiological maturity or some information that contributes significantly to decisions concerning harvest of the seeds is another very important aspect of seed development studies. In many hardwoods, cone/fruit colour was investigated as a workable indicator for maturation, e.g. in five species of *Quercus*[13, 14]. A series of investigations[8] carried out in many agricultural crops, e.g. corn, sorghum, oat, soybean, etc., revealed that the formation of the black layer in corn and sor-

ghum and the changing colour of the fruits and seeds in other species allowed an accurate identification of the physiological maturity of seeds. According to results obtained here, on the basis of pod colour changes in *A. lebbek* it can be concluded that the colour of the pods was closely related to the maximum physiological quality of seeds as they started changing colour from green to yellow around 230 DAA, when seeds had attained physiological maturity. Thus, the time when green pods are not found on the plant any longer can be used to characterize the physiological maturity of seeds, and pods can be collected at this stage. Thus, the overall results obtained here indicate that development of hard-seededness in seeds of *A. lebbek* succeeds the attainment of physiological maturity, and it is an inherent character of the seed which can, however, be delayed to some extent by harvesting the seeds immediately after maturation. The colour of the pods served as a workable indicator of maturation.

Fractal description of seismicity of India and inferences regarding earthquake hazard

K. N. Khattri

Wadia Institute of Himalayan Geology, Dehradun 248 001, India

Earthquakes have the quality of fractal structure in their spatial disposition, time sequencing, and magnitude distribution. We analyse the seismicity of India in terms of its spatial fractal structure in various seismic source zones. It is found that the fractal dimensions range between 0.894 and 1.574, indicating that at most the earthquake associated fractures are approaching a two-dimensional space. The low fractal dimension is suggestive of the presence of asperities and barriers of significant sizes in the respective source zones. Using a fractal model the average earthquake slip in primary faults is estimated to be about 3.5 cm/yr in the Himalaya. This gives an average return period of great earthquake of about 285 years. Considering that no great earthquake has occurred in the seismic gaps in the Himalaya for at least 200 years, these gaps are ripe for a future great earthquake to occur within the next hundred years.

To see a world in a grain of sand,
And a Heaven in a wild flower,
Hold Infinity in the palm of your hand,
And Eternity in an hour.

– William Blake

THE earthquakes represent the outcome of complex geomechanical processes having dire consequences for the society. The earth is in an overall steady state of strain, which for most part is caused by plate motions. This is released from time to time in the form of catastrophic motion over faults in the crust, resulting in earthquakes. The structure of the crust is highly inhomogeneous. On a microscale there are crystal defects, cleavages, dislocations, grain boundaries, etc., while on the other end of the scale, i.e. macroscale, by virtue of repeated fracturing and the different shapes of fractures a high degree of heterogeneity of the crust has evolved. The strain field accordingly is also quite heterogeneous. On account of such complexity of the medium, precise prediction of the occurrence of earthquakes in terms of their location, magnitude and time of occurrence is not feasible. Therefore, the earthquakes are describable by statistical means.

Mandelbrot[1] observed that many natural phenomena possess self-similarity at many different scales. He used the term 'fractal' to describe such phenomena. For example, an assemblage of objects with differing sizes and irregular shapes is a fractal set if the number of objects in it with a specified size has a power law dependence on size. The scaling parameter is called the fractal dimension D. The geometry of the fracture surface of rocks is a fractal[1, 2]. The natural rock fracture process is a fractal. Earthquakes are associated with fractals by virtue of the accompanying fracturing of rocks. A fractal distribution is scale-invariant. In such a set the complexity of the part is as great as that of the whole. A fractal function such as a curve or a surface is not dif-

ferentiable and, thus, no local rule can be deduced to generate the function. However, inferences can be drawn about the whole from observations of the phenomenon on any scale; this is the basis of a holistic approach for studying fractal systems[3]. In comparison, in an ordinary system, howsoever complex it may be as a whole, the basic elements are believed to be simple, which is the basis of a reductionist approach.

Earthquakes possess fractal structure with respect to time, space and magnitude. The Gutenberg–Richter relation for frequency vs magnitude is a power law. Similarly, the aftershock decay follows another power law involving time[4]. The two-point spatial correlation function for earthquake epicentres also displays a power law structure[5–7].

Aki[8] proposed that fractal dimension is correlated with the b value of the Gutenberg–Richter relation. The fractal dimension could be interpreted in terms of the nature of crustal deformations accompanying slips on faults, which may be governed by the sizes and spatial distributions of asperities or barriers in the crust[9]. King[10] and Turcotte[11] have used Aki's model to interpret the crustal deformation due to slips on fractal fault systems. However, Hirata[12] has found that for Japan this idea is not satisfactory.

In this paper we use Aki's[8] model to determine the fractal dimension of seismicity in various source zones in the Indian region and make comparative inferences regarding fault segmentation, asperity–barrier relationships and consequences for seismic hazard estimation. We further use Turcotte's[11] formalism to estimate the fraction of slip taking place on the main fault, the rest being accommodated on a smaller fault system. Thus, we estimate the strain rate and make prognostications about the average return periods of largest earthquakes.

The Gutenberg–Richter frequency magnitude relation is given by

$$\log N\,(m > M) = a - bM, \tag{1}$$

where N is the cumulative number of earthquakes in a time window in an area having magnitudes m greater than M, a and b are parameters of correlation. This relation allows us to estimate the average return period of a future earthquake of a given magnitude, and is, therefore, the basis of preparing probabilistic seismic hazard maps[13].

The Gutenberg–Richter relation represents a power law distribution of magnitudes. Since magnitudes are related to the fault size involved in the earthquake generation, a power law relation for the faults causing earthquakes may be inferred[3].

Another power law relation has been obtained between the magnitude M (surface wave) and the moment M_0 of an earthquake[14]:

$$\log M_0 = d - cM, \tag{2}$$

where c and d are parameters of correlation.

Let both L and l represent linear dimensions. Assuming that the distribution of the earthquake sizes is self-similar and, therefore, the seismic moment M_0 is proportional to L^3 (volume), Aki[8] has shown that a relation, between the cumulative number of faults $N(l > L)$ and L, of the following type may be obtained:

$$\log N(l > L) = e - (3b/c) \log L, \tag{3}$$

where e is a constant.

The power law relation discussed above characterizes the earthquake process. It is appropriate to examine it with the analytical framework for fractals. The parameter characterizing a fractal set is its fractal dimension D.

Let N_n be the number of fragments with characteristic linear dimension r_n in a fractal set; then a power law of the type given below exists for the set[15]:

$$N_n = f r_n^{-D}, \tag{4}$$

where f is a constant of proportionality and D is the fractal dimension. D lies between D_T (topological) and D_E (Euclidean) and may be a fractional number.

Comparing (3) and (4) the fractal dimension for the earthquake process is $3b/c$. An average value of c is estimated to be 1.5 (ref. 13). Thus, on an average, $D = 2b$.

The value of b in various seismogenic zones of the earth has been found to range between about 0.5 and 1.5. Thus, the corresponding fractal dimension can range between 1 and 3. A value close to 3 implies that earthquake fractures are filling up a volume of the crust, a value close to 2 suggests that it is a plane that is being filled up and a value close to 1 means that line sources are predominant[8].

Slip over faults distributed over a region form a major mode of crustal deformation. At the major plate boundaries this slip is driven by relative velocity between the plates. Of the total slip a fraction occurs over the primary fault system causing the largest (and also smaller) earthquakes and the rest on the secondary fault system[11]. An estimate of the proportion of the slip occurring over the primary faults can permit a better estimation of the return periods of the largest earthquakes.

Representing symmetric slip at triple junctions by rhombic plates that together form a regular hexagon, King[10] showed that for fractal distribution of such faults the corresponding earthquakes follow the Gutenberg–Richter relation. Using this concept of fractal matrix of faults Turcotte[11] represents the slip over an extended fault by superposition of slips over the primary fault and that on a fractal distribution of self-similar system of smaller faults. For such a scheme, the following relation for the ratio of the slip over the primary fault to the total slip over the fault system (i.e. due to the relative motion of the plates with respect to each other) is given:

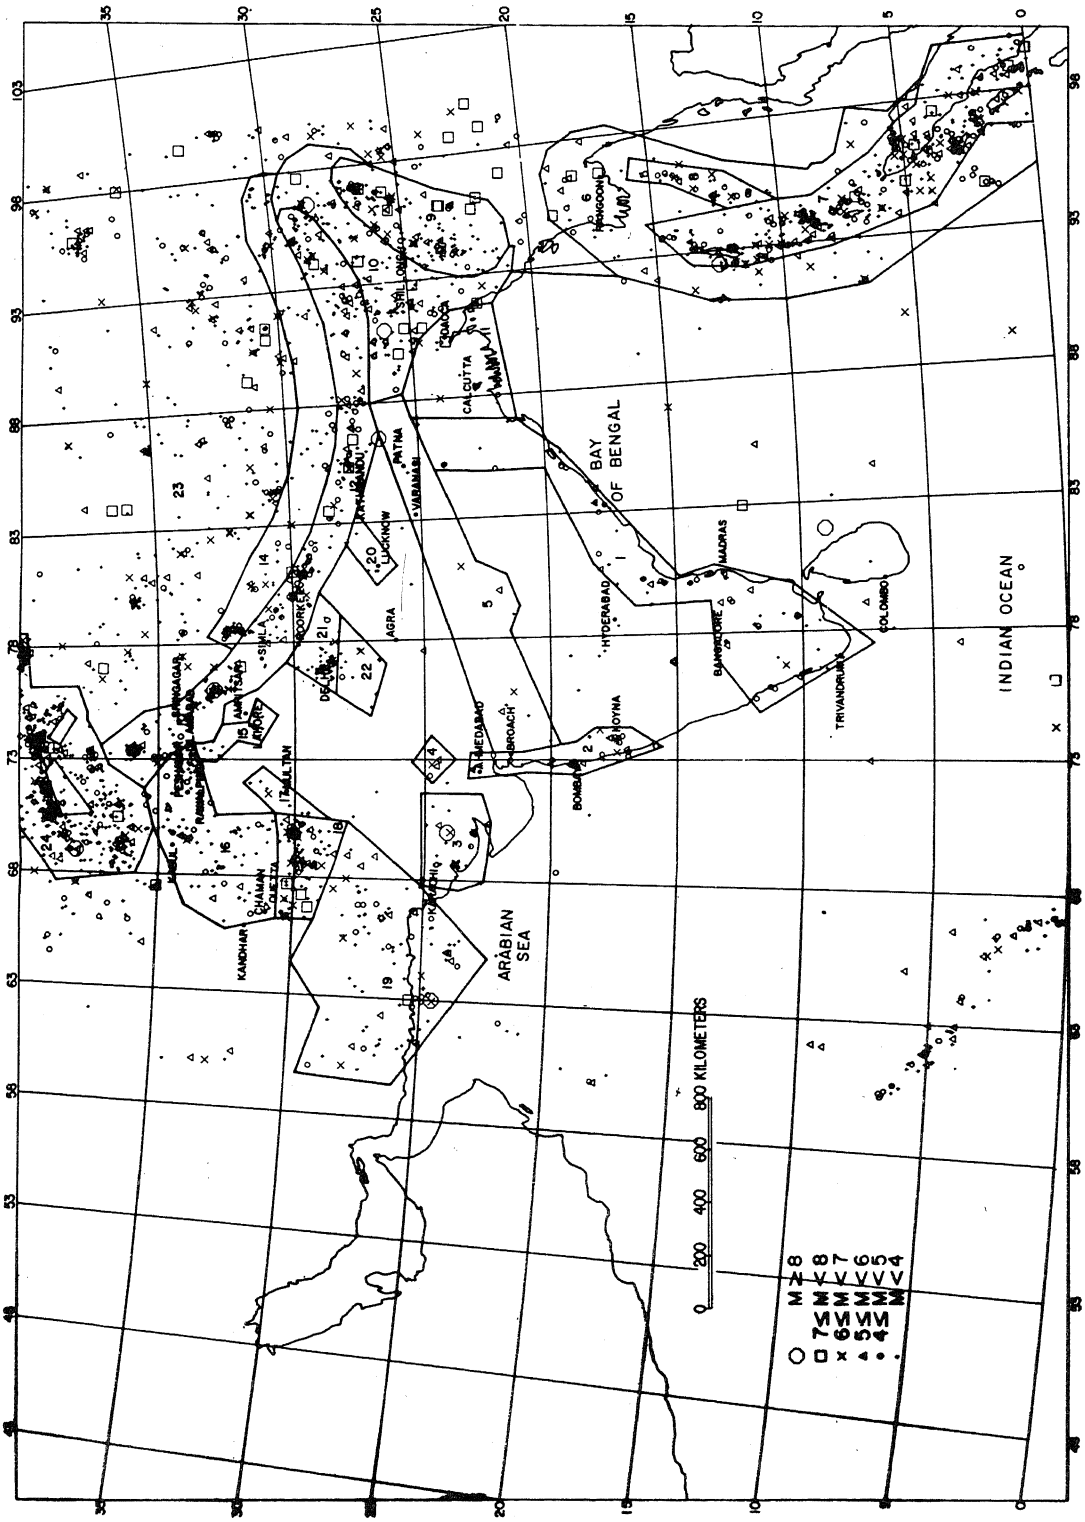

Figure 1. The seismic source zones of Indian region (after Khattri *et al.*[13]).

$$s_p/s = 1 - 2^{-(3-D)}, \quad (5)$$

where s_p is the slip on the primary fault, s the total slip and D the fractal dimension. For $D = 3$ all the slip occurs on smaller faults, whereas on the other end, for the limiting case of $D = 0$, nearly 88% of the slip occurs on the primary faults. The slip that occurs on a fractal system of subfaults contributes to gradual processes like fold formation and other similar crustal deformations.

The seismicity of the Indian region has been examined in detail by Khattri *et al.*[13]. They identified earthquake source regions on the basis of quasi-homogeneity of seismotectonic processes in the respective source regions (Figure 1). The seismicity catalogue was examined and compensated for incompleteness, and the b values were estimated. In some source zones, those in Peninsular India, the seismicity data were not adequate for an independent and reliable estimate of the b values to be made. For such source zones respective data sets were combined and an estimate of the b values was made. The estimates of the b values and the corresponding D values are shown in Table 1.

We note that the fractal dimensions for various source zones range between 0.894 for the Shillong region and 1.574 for the Peninsular region.

The fractal dimensions estimated above indicate that the fractures in the various source zones are filling up either linear regions (low fractal dimensions of ~1) or nearly two-dimensional surfaces (fractal dimension of ~1.5). None of the source zones has a volume distribution of sources.

The largest b value of 0.787 is estimated for the source zones of Peninsular India, for which, as mentioned above, the earthquake catalogues were combined. The compositing of the catalogues of earthquakes for various source zones, possibly having different geodynamic processes, may have a biasing effect towards higher estimates for the b value, as we find in the present analysis. This could be a reason why we get a b value estimate of nearly 1 for the global catalogue of earthquakes. In this light the estimates of D for source zones in the Peninsular region are not reliable.

The low b value and the corresponding low fractal dimensionality obtained for the Shillong region (zone 10) is noteworthy and indicates that there is a tendency for few faults with large attendant earthquakes on them. This may be interpreted to be indicative of a relative lack of fracturing and attendant weaker zones in the region. In other words, the region is characterized by the presence of large asperities or barriers which are relatively unfractured and strong. Similarly, the low fractal dimensionalities of source zone 6 in the Andaman region and 18 in the Sulaiman–Kirthar region imply the presence of significant asperities or barriers.

The Himalaya (source region 12) and the source zone 14 to the north have fractal dimensions of 1.514 and 1.226, respectively. This suggests that the fracture distributions are tending to fill a two-dimensional (2-D) space.

Table 1. The b and D values for the seismic source zones

Source zone	b value	D value	Region
1–5	0.787	1.574	Peninsula
6	0.533	1.066	Andaman
7	0.678	1.356	Andaman
8, 9	0.580	1.160	Andaman, Arakan
10	0.447	0.894	Shillong
11	0.787	1.574	Bengal Basin
12	0.757	1.514	Himalaya
14	0.613	1.226	Trans Himalaya
15	0.787	1.574	Himalaya foredeep
16	0.581	1.162	Sulaiman
17	0.787	1.574	Sulaiman foredeep
18	0.485	0.970	Sulaiman–Kirthar
19	0.581	1.161	Kirthar–Makran
20, 21	0.787	1.574	Himalaya foredeep
22	0.787	1.574	Peninsula
23	0.543	1.086	Tibet
24	0.561	1.122	Hindukush

The other source zones are characterized by fractal fracture distributions ranging in between the two end types discussed above.

Following Hirata[12], we calculated the 2-D fractal dimension D_2 using the correlation integral $C(r)$ defined with respect to the spatial distribution of epicentres. It is defined by

$$C(r) = [2/\{N(N-1)\}]N(R < r), \quad (6)$$

where $N(R < r)$ is the number of pairs of epicentres with a mutual distance R smaller than r. N is taken to be 865 events. The value obtained is 0.275. Now D (in Aki's definition) is the volume dimension (3-D). Thus,

$$D = D_2 + 1,$$

from which we obtain a value of 1.275 for D. The value obtained from the b value is 1.514. The two estimates are reasonably close. As noted above, it was not so in the case of the Japanese earthquakes[12]. Thus, we consider that the present analysis is valid.

We next consider the estimation of the slip on the primary fault in the Himalayan collision zone. The convergence rate between India and Asia is estimated to be 5.5 cm/yr. Of this a fraction is released on the primary fault and the rest on the fractal distribution of subfaults. The primary fault is considered to be the basement thrust[16], on which the largest earthquakes occur. This is a north-dipping surface constituting a megathrust extending along the Himalaya for about 2400 km and having an average width of approximately 80 km. It is desirable to estimate the fraction of the total convergence rate released over this fault, as that would enable one to estimate the average return period of great damaging earthquakes. In the present analysis the source zones 12 and 14 are considered to be the main players in

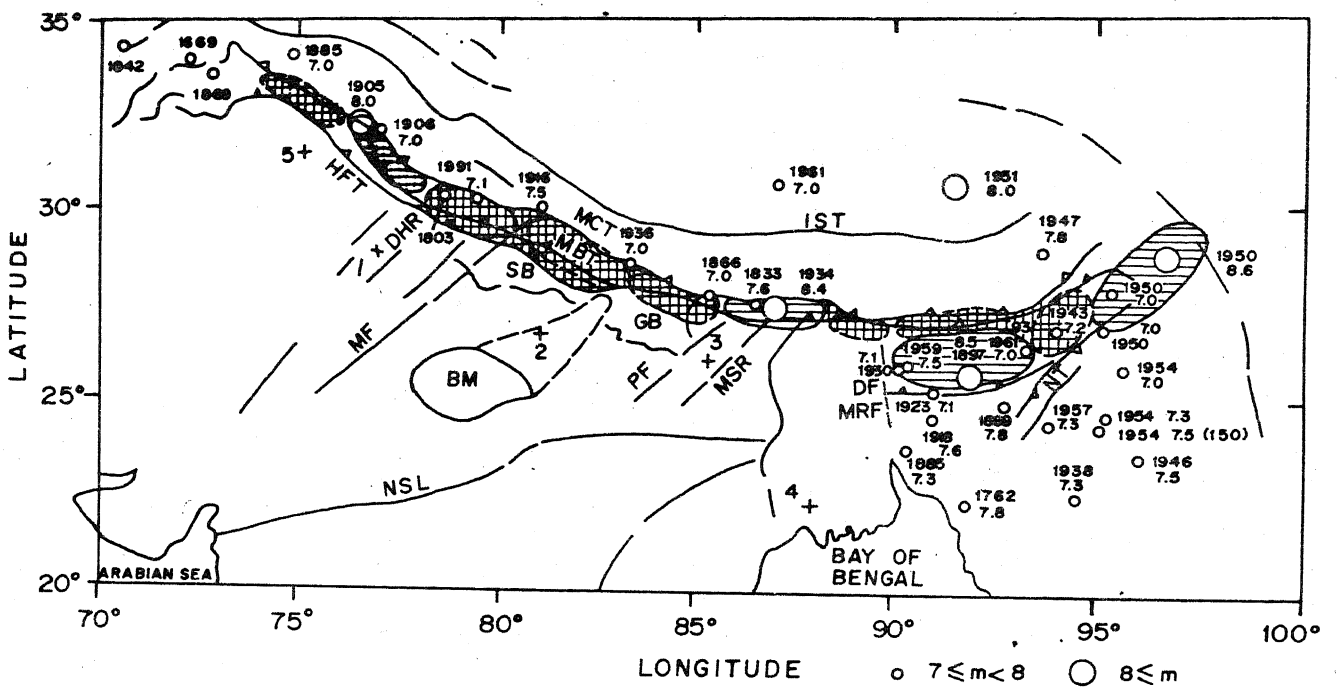

Figure 2. The larger earthquakes of Himalaya. The rupture zones of the great earthquakes are shown by hatured areas. The outlines of the sections of the seismic gaps that may rupture in a single earthquake are marked by dashed lines. It is possible that the central seismic gap may rupture in a single great earthquake[20]. 1: Delhi; 2: Lucknow; 3: Patna; 4: Calcutta; 5: Lahore; BB: Bundelkhand massif; DF: Dauki fault; DHR: Delhi–Hardwar ridge; GB: Gandak basin; HFT: Himalaya frontal thrust; MF: Moradabad fault; MRF: Madhupur fault; MBT: main boundary thrust; MCT: main central thrust; MSF: Monghyr–Saharsa ridge; NSL: Narmada Son lineament; NT: Naga thrust; PF: Patna fault; SB: Sarda basin (after Khattri[22]).

releasing the strain. Further, the source zone 14 comprises of only the fractal subfaults, the primary fault being confined to the source zone 12. Since the fractal dimensions in the two source zones are quite close, we take the value for the same from source zone 12. Using this value in equation (5) we obtain a value for slip rate s_p on the basement thrust to be approximately 3.5 cm/yr. The remaining slip is released on the smaller fractally distributed subfaults. Thus, on an average, for a magnitude 8+ earthquake involving 10 m of slip a time interval of 285 years will be required. The average slip rate for underthrusting is estimated to be of the order of 1.0–2.5 cm/yr (ref. 17) from moments of large earthquakes and geological evidence, 1.5–2.2 cm/yr (ref. 18) from GPS measurements in Nepal section of the Himalaya, and 7 ± 4 cm/yr (ref. 19) from geodetic measurements using levelling. All these estimates are of the same order of magnitude, with the estimate for the slip rate obtained here being somewhat higher. If part, say, one-third, of the slip on primary faults is taken up in source zone 14, then the estimate obtained here will be almost totally congruent with the other estimates. We note that while the geological estimate is an average over several million years, the estimate from GPS data is instantaneous. One of the two estimates derived from earthquake data is based on a period of most recent, about a couple of hundred years, data and magnitudes ranging from smaller to largest earthquakes, while the other one is derived on the basis of great earthquakes only. The estimate from levelling data refer to a period of a few decades. The consistency of estimates derived by such a diversity of databases as well as concepts serves to instill a measure of confidence in the estimated value.

The Himalayan plate boundary has experienced four great earthquakes ($M > 8$) in 1897, 1905, 1934 and 1950, which ruptured and relieved accumulated strains over about 200–300 km long sections (Figure 2). These earthquakes have left sections of the plate boundary where the accumulated strains have not been relieved for at least 200 years; these sections form the seismic gaps[16–26]. The large earthquakes in the Himalaya are recorded from 1803 onwards and a total of 15 with magnitudes (estimated from damage reports for earthquakes in the previous century) between 7.0 and 7.6 have occurred. Of these, two are aftershocks of the great 1950 Assam earthquake and one of the great 1905 Kangra earthquake. One of magnitude 7.6 occurred in 1866 in the rupture zone of the subsequent great 1934 Bihar–Nepal earthquake. Four events, in 1923, 1930, 1959 and 1960 have occurred in the rupture zone of the great Assam earthquake of 1897 and may be considered to be its aftershocks. One event has occurred in 1943 in the Assam gap.

An 800 km long central seismic gap exists between the rupture zones of the Kangra and the Bihar earthquakes. It is possibly divided by transverse geological structures into three sectors. The first lies between the Delhi–Hardwar ridge (eastern margin of the 1905 Kangra rupture zone) and the Moradabad fault, the next is between the Moradabad fault and the Bundelkhand massif promontory, and the third one is between the promontory and the Patna fault. The first sector has had earthquakes in 1803 and 1991. One event occurred in line with the Moradabad fault, another event occurred in 1866 in a region aligned with the Patna fault. The average slip in a $M \sim 7$ earthquake is of the order of 1–2 m. This has been released over faults having relatively small areas, in various parts of the central sector, through such earthquakes since 1803. The cumulative fault area (overall $M \sim 7$ earthquakes) is estimated to be merely about 4500 km^2. On the other hand, the seismic gap has accumulated a slip of at least 5–7 m over an area of 48,000 km^2 (length of about 800 km). This slip accumulation would be much more in case the last great earthquake in the gap occurred 300 or more years ago. Thus, this and similarly the Assam gap have very high potential for giving rise to great earthquakes in the not too distant a future (within about 100 years); depending on how far back in time the last great earthquake ruptured these seismic gaps, the next one may be advanced in time accordingly. In this connection it may be noted that the earliest report of a damaging earthquake in northwest Himalaya appeared in 1669 and in Nepal Himalaya in 1833 ($M = 7.6$). Thus, we may reasonably conclude that an earlier great earthquake in the Himalaya has occurred prior to the 18th century. This already gives at least 300 years of strain accumulation.

The seismic zone of the Himalaya has a fractal dimension lying between 1 and 2, and may be taken to behave approximately as a planer zone. On the other hand, the Shillong massif region has a fractal dimension of less than 1. Thus, this region is relatively dominated by the presence of asperities and/or barriers.

The results of the present study supply confirmatory evidence supporting the conclusions arrived at by earlier studies[16–26] that the seismic gaps in the Himalaya have considerably increased potential for the great earthquakes to occur within the next 100 years or so.

Therefore, there is an urgent need to recognize the above findings regarding the lurking earthquake disasters. The public and government opinions need to be mobilized for a well-planned effort for intensive earthquake studies in the Himalaya, which at present are at a very rudimentary plane. Also there is an urgent need for mounting on a war footing a systematic earthquake hazard mitigation plan to ameliorate the disastrous consequences from future earthquakes.

ACKNOWLEDGEMENTS. This research was supported by a CSIR–ES scheme and the host institution, the WIHG. I am indebted to P. K. Roy and S. S. Teotia for nudging me into studying earthquake phenomena using the framework of fractals, and also for stimulating discussions.

Received 12 August 1994; revised accepted 5 May 1995

Beyond the Quantum Paradox. Lazar S. Mayants. Taylor and Francis, London. 1994. pp. xi + 105. Price: £9.95.

Among the numerous attempts, of late, to develop a correct point of view in respect of quantum mechanics, this book claims to offer a rather straightforward solution. In doing so some will say it goes a bit too far as, for example, in postulating the existence of emons, i.e. 'concrete' electromagnetic quanta with nonzero mass, even though such ideas have been suggested by others in the past from time to time. To take the last issue first, the case for nonzero mass for the quanta of electromagnetic fields is taken to be based on the formulae[1]

$$p_x = mc\beta_x, \quad E = mc^2, \quad m = m_0\eta^{-1}$$

$$(1 \le \eta^{-1} < \infty), \quad \eta^{-1} = \frac{1}{\sqrt{1-\beta_x^2}},$$

so that if $m_0 = 0$, then $m = 0$ even if $\eta^{-1} \to \infty$ when $\beta \to 1$, and if $m = 0$ then both p_x and E are identically zero. For a nonzero electromagnetic field to exist, m_0 and m must also be nonzero. One may rightly express one's worries here about trying to extract meaning out of expressions like $0 \times \infty$, or 0/0, etc.

The above is, however, only one of the conclusions to which the author is led to, in view of what he calls his principal principle, which is that in dealing with statements involving probabilities and statistics, one should never confuse the 'concrete' object for the abstract object. The simplest way to explain this by the author is to take the case of balls of different colours in a bag. When we talk, he says, of 'a ball in the bag', this is an abstract object which theoretically can possess any one of those different colours, but when we pick a concrete ball out of the bag it has one definite colour only. Statements of probabilities are always about abstract objects, whereas statistical experiments are always done with concrete objects.

Regarding Schrödinger equation, he says, it refers to the situation when the expectation value of the Hamiltonian of the system coincides with the expectation value of the energy of the particle, the wavefunction serving merely as an auxiliary mathematical device for calculating probabilities.

As an illustration of his views, Mayants proceeds to demolish the various quantum-mechanical paradoxes, like Schrödinger's cat paradox or the EPR-Bohm paradox, etc., by simply using his principal principle. In doing this he attempts to emphasize the role of classical concepts even though he does recognize the peculiar role of the superposition principle in calculating quantum-mechanical probabilities. About the Schrödinger's cat paradox, for example, he says that the 'concrete' cat has only one of the two possible values 'dead' or 'alive', of the property 'state of being', whereas an abstract cat does not exist in reality at all. The double-slit experiment is a Gedanken experiment, claims Mayants, because in an actual experiment the separation between slits should only be of the order of a few wavelengths. Bell's theorem, claims the author, has impeccable mathematics, but its premises are wrong. Bell's theorem is not followed in practice because spin values for the same concrete particle for different axes are not permissible. The only thing Bell-like arguments can prove, claims the author, is that quantum physics is incompatible not so much with realism as simply with determinism, which, in any case, being a probability-based theory, is as opposed to a nonprobability-based theory like nonstatistical classical mechanics.

Mayants argues that the situation in the EPR paradox is the result of the law of conservation of momentum and his principal principle, and that there is no action-at-a-distance, no 'knowing' of the result of measurement on one particle by the other. He, in fact, denies any connection between the Bell-inequalities-related experiments and the concrete mechanical system of the EPR, which latter belongs, he claims, to classical mechanics. Regarding Bohm's experiment, he says that it is meaningless to talk of simultaneous values of spin for different axes for a concrete system. Assuming conservation of angular momentum and his principal principle, the experimental outcome of Bohm's experiments is explainable, he claims, without further ado. Similarly, assuming Malus'es law, the principal principle and what is termed as the law of conservation of polarization, the experiments of Aspect *et al.*[2] are also sought to be explained, and it is claimed that there remains no paradox. In dealing with Wheeler's delayed-choice experiment, says the author, the outcome is determined by the last-moment choice, and not by the delay, as the concrete photons can be thought of as being emitted by two different sources, and interference-like effects then arise because of cross terms occurring when squaring the total wavefunction in getting the probabilities.

In contrast to the claims made by Mayants regarding the observance or otherwise of inequalities due to Bell (as also, by implication, due to Clauser–Horne, and others), Pitowsky[3], for instance, goes on to show convincingly that quantum frequencies often violate the facet inequalities of the correlation polytopes. Indeed, Pitowsky claims that violations of the above inequalities by quantum frequencies pose a major problem to all schools of classical probability. Much earlier, Strauss[4] had shown that the algebra of projectors in Hilbert space is only partially Boolean if complementarity in the Copenhagen sense was to be maintained. Even though experiments testing Bell inequalities have more than reaffirmed quantum-mechanical peculiarities, including nonlocalities, Mayants would have none of this. Like Einstein at one time, he would, as stated above, deny even the very existence of uncertainty relations if interpreted in terms of measurement as done by Heisenberg. The author feels strongly that Heisenberg's uncertainty principle deals with abstract quantities and that, therefore, Heisenberg's original interpretation in terms of experiments with concrete objects was wrong. The free particle and the harmonic oscillator cases, he says, violate the principle $\Delta p \cdot \Delta x \ge \hbar/2$, because for the free particle, for instance, $p = \text{constant}$ implies $\Delta p = 0$, giving $\Delta p \cdot \Delta x = 0$ and not $\hbar/2$.

The author does not think it proper to so much as even mention either the deterministic or the stochastic hidden-variable theories, or the many-worlds or many-minds interpretations of quantum mechanics nor does he think it fit even to mention or discuss such important topics as the reduction of the wavefunction, while rejecting nonlocality offhand. The result is that there are strong statements in the book without the provision of adequate justifications.

One is tempted to think that Mayants' plunge for a 'concrete' ontology, and semblance of an attendant realism may have been motivated by the fact that violation of classical constraints like the Bell inequalities can be taken to imply

antirealism, because, like a Humean skeptic, the antirealist may hold that quantum physics does not deal with causes but with phenomena only, and in a world without causes, 'anything goes'. In the event, however, Mayants ends up making sweeping statements which a more careful analysis may show to be wrong.

The chapter entitled 'Personality versus society' of the book seems out of place in what purports to be an account of the way out from the quantum-mechanical paradox, unless the author intended to show that he was demolishing the myths, he saw, of quantum mechanics, in much the same way as he would demolish the myths perpetrated in the name of dialectic materialism and social formation under communism!

All said and done, the principal principle enunciated by Mayants is something to be kept in mind when talking about probabilities and statistics in quantum mechanics, as in any probability-based theory, but, in spite of claims to the contrary by the author, this in itself can hardly be expected to obviate the need for further analysis of the foundational aspects of quantum mechanics.

The final answer, instead of lying with Mayants, may indeed lie somewhere else, based as it would be, on a more careful analysis of issues such as the superposition principle and entanglement, time evolution and reduction of wavefunction, and, of course, nonlocality, and then it would indeed be found, as shown by Redhead[5], that 'quantum mechanics has landed some pretty queer fish'.

The Action Principle in Physics by R. V. Kamat. IPA monographs in physics series. New Age International Publishers Limited, Wiley Eastern Limited, 4835/24 Ansari Nagar, Daryaganj, New Delhi. pp. 201. Price: Rs 400/-.

Given the large number of students which flock to various postgraduate departments in Indian universities every year, the near total lack of books by Indian authors written specially for Indian students, either as basic textbooks or for supplementary or follow-up reading, is quite remarkable. While it is certainly true that most of the students would rather watch TV than study books in their spare time, and bogged down with heavy course loads as they are, certainly not 'outside-the-course' monographs, this is not a sufficient explanation. For, even if only, say, 5% of the students are seriously interested in their subjects, we are still dealing with large numbers. That they do not do so much is partly because reasonably priced books, pegged at an appropriate level, are not easily available. Clearly, here is a Catch-22 situation.

While there are a large number of monographs of good quality published abroad, these are usually not available to Indian students. Most university libraries are in bad shape. The high price of books is a very major deterrent. Also, not many bookstores kept many specialized monographs in stock, and ordering them from publishers can take 6–9 months (who can afford air mail?). It seems quite unreasonable to expect a student to have sufficient patience and sustained interest for so long. 'In the final year, sir, we study other subjects.' The students are like that only.

The Indian Physics Association, by publishing monographs meant for Indian students of postgraduate level, or first year of Ph D is providing a much needed input. The volumes are reasonably priced, and the prices, hopefully, could be brought down further if the series proves popular. It is reasonable to expect that Indian authors would have a much better understanding of mathematical or conceptual difficulties faced by Indian students and, thus, would be better able to adapt the material to our needs. It is an idea whose time has come.

The present volume is by R. V. Kamat, who has been teaching physics students in St. Xavier's College, Bombay, at both undergraduate and postgraduate levels for over 20 years. It deals with the action principle in classical mechanics, electrodynamics, general relativity and quantum mechanics. The book starts with simple problems in calculus of variation, e.g. the famous brachistochrone problem and Fermat's minimum time principle in geometrical optics. These chapters have a large number of problems, of which at least some will be enjoyed by interested readers. This is followed by discussions of Hamilton's principle in classical mechanics. This is a fairly standard fare for M Sc (Physics) students and is dealt with quite satisfactorily here, as also in most standard textbooks on mechanics. The next chapter deals with the action in classical electrodynamics, and derivation of Maxwell equations, starting from the corresponding action.

The author has been careful enough to recaptitulate some of the concepts, and the covariant notation of the special theory of relativity. These are followed by chapters on the action principle for general relativity and for quantum mechanics, however avoiding a full-blooded path integral formulation (that would perhaps require a book on its own). A chapter on action-at-a-distance for much of electrodynamics, which avoids introducing electromagnetic field as a separate entity and defines direct but 'delayed' action-at-a-distance between charges (as proposed by Fokker and Schwartzchild and developed later by Wheeler and Feynman), has been added perhaps as a teaser for students to pursue the subject further.

The book is suitable for M Sc (Physics) or first-year M Phil students. It has a judicious mix of conventional 'textbook material', and somewhat more advanced topics which are usually found only scattered in different textbooks on electrodynamics and relativity of quantum mechanics. The book thus brings out an important unifying principle in physics, in a language accessible to students.

On the debit side, the price of the book at Rs 400 for 200 or so pages is not really low. The number of typographical errors is quite large for a textbook meant for students. It is hoped that

these will be corrected in the next printing. The problems in the latter part of the book are quite routine, of the kind 'verify Eq. 7.8'.

An important topic which has been omitted is the euclidean field theory, which makes contact with the minimization principle of free energy in thermodynamics. I think that it is technically, conceptually and, hence, pedagogically simpler as it deals with real integrals of the type $\int_{-\infty}^{+\infty} \exp(-x^2)\,dx$, and not complex and not absolutely convergent ones like $\int_{-\infty}^{+\infty} \exp(-x^2)\,dx$. Some jargon-free discussions of if and how causality is maintained even with advanced wave solutions in Chapter 8 would have been very useful, and also would have helped the students think about the physical ideas behind the mathematical formalism.

On the whole, the book is a welcome effort to bring good books to Indian physics students at a reasonable price. It is recommended for acquisition by libraries of institutions involved in physics teaching at M Sc or Ph D level, and also by students who want to go a bit beyond the conventional curriculum.

DEEPAK DHAR

Bombay 400 005, India.

Laboratory Manual of Organic Chemistry. Raj K. Bansal. Third Edition. Wiley Eastern Limited, New Delhi. 1994, 290 pp. Price: Rs 80.

An author who sets out to write a guide on practical organic chemistry for Indian universities is faced with a choice between two evils. Given the backdrop of a tradition-bound, rigid system (wherein innovation is frowned upon), the book has to meet the demands of the existing (though outmoded) syllabi to make commercial sense for both the author and the publisher, or face oblivion. An innovative guide which sets out to correct the course of practical organic chemistry within this country would have few takers. The bulk of the colleges (over 7000) are nothing more than factories churning out graduates within the rigid norms imposed by the examination systems, that establish a uniformly low level by sticking to the letter (not spirit) of the syllabi. The handful of autonomous colleges/institutions who have the resources to modify and innovate either do not have an undergraduate programme or have chartered their own different courses. Writing a book for this miniscule market makes no commercial sense. Unfortunately, what makes commercial sense has very little professional value. Chemistry being a professional science (which has given birth to several professions and even today continues to churn out new professions) should have a dynamic practical course to prepare students to meet the demands of the present job market and future challenges. One would like to see a practical guide which contains not only classical areas, including spectroscopy, but also a good sprinkling of professional skills such as clinical chemistry (biochemistry), pollution chemistry (air and water monitoring), detection of adulterants in food (forensic science) and some basic industrial chemistry. It should set out a model framework for undergraduate (UG) and postgraduate (PG) courses to make the practical courses relevant to the job market. Alas!! an author who sets forth on this trial would have to wait for the world around him to change, for no publisher would support such a venture.

It is against this background that one should view this book. While Bansal has kept in mind the overall needs of the Indian universities, there are some curious features. It is hard to see why any college would like to store 11.5×40 (students) = 460 g of picric acid prepared every year. Several such preparations appear to be there for old times' sake. The analytical organic chemistry experiments baffle this reviewer. Let us assume 14% nitrogen/sulphur/halogen in a given organic compound. If one takes 2 mg of sodium and an equal quantity of the compound (but does not the grand master A. I. Vogel state that the compound should be added to molten sodium) per ignition tube and 15 ml of water, one could hardly expect 0.02 mg of cyanide/sulphide/halide, assuming 50% reaction (which is impossible under the conditions). Should one depend on precipitation tests for sulphide? The existence of sulphocyanide in a very dilute alkaline solution is also questionable (if tests are performed as per procedures on pure organic compounds). In the same way, several other functional group tests are also of little practical value. The heavily curtailed list of common organic compounds indicates clearly that the author wishes to weed out items which are seldom given for UG and PG classes. This laudable objective could have been stretched to other procedures such as estimations. The section on organic preparations has several important and useful procedures for classroom work. Considering the financial crunch, the scales of these preparations are generally large. The section on spectroscopy stands alone without connectivity. The cost of organic analysis could be drastically reduced and the training made more realistic to real-world situations by combining classical and spectroscopic approaches. After N, S, halogen test and m. p. determination, the student could analyse the given (photocopy) infrared (IR) spectrum. The functional groups deduced from IR could be confirmed by chemical tests and derivatization. Listing the derivative under different functional groups could send wrong signal to students. For example, the phenolic group is identified by the $FeCl_3$ test, solubility tests and preparation of a benzoyl derivative. However, an easy derivative for some phenols (and aromatic amines) could be via nuclear bromination. A good derivative for quinol is *p*-quinone, by $FeCl_3$ oxidation. Some glaring errors in figures and structures in this third edition could have been avoided (e.g. water pump (p. 11), thiourea (p. 142), α-bromo-β-napthol (p. 158), piperine (p. 236), etc.).

Notwithstanding some drawbacks, the book meets the demands of most of the syllabi. The discussions and procedural details have been trimmed to a minimum to keep the book affordable to students, who should also find the discussions on mechanisms and chemical equations very useful in understanding the procedures. As frequently suggested in the text, the instructor should provide supplementary guidance, bearing in mind that brevity has its own pitfalls. On reduced scales, the experiments on

named organic reactions would prove to be of good instructional value. Students should find this book affordable and useful for routine laboratory work.

R. BALAJI RAO

Department of Chemistry,
Banaras Hindu University,
Varanasi 221 005, India.

Perspectives in Nematode Physiology and Biochemistry. M. L. Sood and Jyotika Kapur, eds. Narendra Publishing House, 1417 Kishan Dutt Street, Maliwara, Delhi 100 006. 1995. 302 pp. Price: Rs. 575/-, $ 69.75.

Nematodes, much like insects, are one of the most abundant animals, both in their numerical strength as also in the number of species. While insects are very conspicuous by their presence as also because of some 800,000 known species, the knowledge of nematodes with only about 30,000 known species is very scanty because of their hideous and illusive nature, small size, concealed habitats, colourless bodies and the difficulties that are generally encountered in their collection and isolation. In the last 2 to 3 decades, because of the interest that has been generated due to their economic importance, nematology has fast emerged as an important area of parasitology, helminthology, plant nematology as also that of agricultural and biological sciences. There were not many text/reference books on nematodes until recently, more particularly from India. With this background, in my mind, I naturally was very excited by the mere sight of this book, more so because of its title. But my enthusiasm turned into disappointment as I read through the book.

Keeping in view the paucity of information on the physiology and biochemistry of nematodes, one would have expected some well-knit, properly interlinked, and thoroughly edited write-ups, but what we have in its place are some essays on certain aspects of physiology and a couple of them on biochemistry as well. It is interesting to note that two of these write-ups are by scientists who have not even made any contributions, as judged from the bibliography provided, in the area on which they have contributed the articles. Some other topics like 'Test parasites and nematicidal drugs', though of significance and academic interest, do not actually strictly fall under the title of the book. Similarly, the article on *Ascardia galli* appears more to be a Ph D research topic rather than a review article and the same should merit publication in a journal rather than in this book. However, from these remarks it should not be inferred that the book does not have merits and the information contained therein is totally devoid of value and utility. The articles by Bone, Boczone, Srivastava and Batra, Harnett and Parkhouse, etc., are exhaustive, up-to-date and praiseworthy.

I feel that the editors have missed a great opportunity of producing a useful book on such a challenging subject. The choice of topics should have been a more careful one. It also appears that the various contributors did not get proper guidelines from the editors and as a consequence the various write-ups do not appear to be the parts of the same book. It is also strange that no detailed introduction or preface precedes the articles. The quality of printing and the general get-up of the book is satisfactory. There are some typographical and printing errors, which should have been avoided.

Ocean Technology – Perspectives. Sushil Kumar, Vikram V. Agadi, M. Keshava Das, B. N. Desai, eds. CSIR, New Delhi. 1994. 989 pp.

The International Indian Ocean Expedition of 1960–65 was the first attempt in the country towards systematic studies of the seas around India – culminating in the establishment of the National Institute of Oceanography (NIO) at Goa, which has since been in the forefront of oceanographic research in the country. Besides NIO, research in ocean science and engineering is carried out in more than a dozen research institutes, IITs and universities. A glimpse of the contemporary work in the country in ocean technology is given in the book under review. The book is a compilation of 95 papers presented at a national symposium organized by NIO in August 1992 as a part of the CSIR Golden Jubilee Celebration, to which it is a fitting tribute.

As the title of the book indicates, more than 80 papers deal with different topics in ocean technology and the remainder with ocean science, except for one odd paper on wave propagation in alkaline metals, which is not relevant to the theme of the book. It would have been convenient to the reader, if the editors had grouped the papers under different subheadings. On a study of the book, the following topics can be identified with more than 4 papers in each: ocean waves, wave forces, ocean bed surveys, oil field development, remote sensing, corrosion and biofouling, pollution monitoring and control, biotechnology, deep-sea mining and marine instrumentation. On about a dozen other topics of oceanography, there are one or two papers each. A glaring omission is the subject of deriving electrical energy from the oceans (on which at least three agencies have been working in this country), except for a single paper and that too on the concept of an ocean-coupled solar pond for conversion of thermal energy into electrical power.

There are four papers on marine survey systems and techniques – the very first paper on survey for engineering applications, two papers on the multi-beam sonar for seabed mapping and a review paper on current trends in underwater operations and tools used.

A wide variety of problems related to the design and performance of coastal and offshore structures, guyed towers, tension leg platforms and moored buoys in the presence of ocean waves and currents is discussed in over twenty articles, which will be of immense use to a designer. Four papers which deal with techniques of wave measurements, wave modelling taking into account transformation processes in shallow waters, will be useful in estimating the design wave parameters. A paper on tidal currents in shelf regions deals exhaustively with both theory and practical measurements.

The problem of corrosion in cement, concrete and steel structures in marine environment as well as techniques of studying the corrosion process and corrosion fatigue in metals and biofouling in power plants are discussed in six articles, and will be valuable to engineers.

Out of the twelve papers on marine instrumentation, nine present original work on the development of new instruments, some of which have been field-tested and merit consideration for commercial production, and three give overviews of commercial systems of foreign manufacture and data management systems. The instruments are used for integrated data acquisition and measurement of water quality: spectral irradiance, underwater thermal profile, ambient noise, tidal heights, subsurface currents and core sampling. The article on nondestructive testing is just a review article on current techniques.

An excellent set of eight papers deals with satellite oceanography, namely techniques for deriving from satellite data information on fish abundance zones, littorial sediment transport, sea surface temperature and mixed-layer depth, atmospheric moisture content, surface wind and wave, latent heat flux and bathymetric features. With the advantage of getting synoptic data over wide regions at periodic intervals from the satellites, these papers will be valuable for research studies and applications.

Another topic of contemporary interest, namely, exploration for and exploitation of polymetallic modules in the central Indian Ocean, as well as the environmental protection aspects while mining, is dealt with in about fifteen papers which merit careful study.

Environmental pollution, in particular oil spilling, is the subject of five papers; the use of microbes for oil degradation or recovery is discussed in four papers. Other aspects of biotechnology, such as processing seaweeds for drugs, are discussed in three papers.

Among the fifteen papers dealing with different aspects of ocean science, some are significant and worth follow-up, such as the spatiotemporal variability of biological and physical fields, simulation of acoustic propagation, storm surge modelling, classification of acoustic echoes from seabed with broadband signals and directional response computation for an arbitrary acoustical array for broadband signals.

The usefulness of the book would have been enhanced by introducing each of the ten major topics with a summary of the present status as revealed in the papers and the perspectives for future. A symposium of such a high order as the one under review would have seen valuable discussions at the end of presentation of each paper and their inclusion would have further enhanced the value of the book. However, even in its present form, the book is highly informative and will be valuable to any research worker in emerging fields of ocean technology.

Botany in India: History and Progress. Vol. I. B. M. Johri, ed. Oxford & IBH Publishing Co. Pvt. Ltd., 66 Janpath, New Delhi 110 001. 1995. xxxi + 521 pp. Price: Rs 950.

The above publication, a multiauthored volume, comprises consolidated information primarily on lower groups of plants from India. During the past three decades or so, there has been phenomenal increase in research activities in the country not only on fundamental aspects of botany but also on several new disciplines/aspects that have been initiated and fruitful research conducted on them. The volume of research publications has been enormous and it is difficult to keep abreast of the information on all the facets of one's own speciality, leave aside botany as a whole. Almost all the contributing authors (except probably one) of the above volume are well-established specialists in their own fields of research and have, therefore, done a fair job of assembling and arranging the research information under neatly segregated sections and subsections. One is often tempted to be subjective in such write-ups, but it is creditable that invariably almost all chapters have an objective approach in their contents.

Historical accounts for the different groups of plants of India have been published earlier at intervals, but probably reviewing them at the beginning of each chapter was evidently a necessity for understanding the continuity of research progress of the subject matter in the subsequent period of time. This has in some cases entailed a partial repetition in some chapters (on fungi).

The title of this publication, in a strict sense, indicates that it gives information only on botanical research carried out in India on Indian plants, by Indian and foreign nationals. Exotic plants studied in India, such as *Tmesipteris* spp. by Sahni at Lucknow (p. 456), could also come in this category. The studies on Indian plants carried out in foreign countries by Indian or foreign nationals, such as *Flora of British India* by J. D. Hooker (p. 22) worked out at Kew (this fact is withheld), actually represent 'botany *of* India', and such instances get confused or even synonymized as 'botany in India'. However, research on exotic plants carried out outside India by Indian nationals is *certainly not* 'Botany in India', and the editor has been irresolute in allowing such information in the publication to persist, (examples given later).

Since an up-to-date consolidation of information on different branches/aspects of botany in India was not available at one place, the above publication is a welcome venture, which will positively provide referential information to postgraduate students of botany for competitive tests, selection of research topics/disciplines/branches to be pursued at particular centres of that speciality in the country. It may, however, be mentioned that the university botany departments are dynamic as far as the specialities are concerned, because they change with the change/retirement of the personnel – a universal phenomenon, and the specialities in the universities may not necessarily be existent.

The matter dealt with in the different chapters is of high standard and detailed, certain chapters being *par excellence,* having been prepared by specialists with large number of publications to their credit. A major part of the book (Chapters 4–24) deals with the lower groups of plants (viruses, bacteria, algae, fungi, lichens, bryophytes and pteridophytes – some of which were earlier known as cryptogams).

An exploratory history and publication of numerous floras (entirely angiospermic) along with the institutions/agencies known for angiosperm taxonomic work have been outlined in Chapter 2. A much detailed and interesting exploratory history by K. Biswas (in 1943) has apparently not been consulted as there is no citation under the refer-

ences. Information about the number and the presence of the total holotypes/isotypes of Indian angiosperms preserved in Indian herbaria, a must for taxonomical work, is lacking. Information on plants for medicine (Chapter 3), primarily angiospermic in content, could have been more comprehensive, and would probably have been appropriately included in Volume II of Botany in India, where several other aspects of angiospermic research have been envisaged to be published.

In Chapters 4–24 (except 20) the approach to each group of plants is somewhat on similar lines in respect of historical account, structural morphology, taxonomy, physiology, genetics, ultrastructure, etc. Detailed information on the characteristics of the individual groups is well treated. Unfortunately, Chapter 20 on lichens reveals lack of understanding of the concept of lichens and lichen components ('... dearth of information on the mycobionts of Indian lichens', fruit body 'perithecium in *Cetraria*' – an absurdity), inaccurate statements ('lichen research initiated at the University of Lucknow by Biswas'), prominence to the work on foreign lichens outside India, and several misspelt terms and lichen names.

The following shortcomings/inaccuracies need reporting so that errata may be published if thought proper:

1. Citation of plant species under abbreviated generic name without the full generic name *immediately* preceding, and if preceded intervened by other genus or genera is liable to cause confusion if the first letter of the genera is the same.

2. Inaccurate statements (e.g. p. 456): 'Sahni (1915, 1916), at Lucknow, ...'. Sahni was at Cambridge University during those years. He joined Lucknow University in 1921.

3. Matter not eligible for inclusion in this book:

(i) Sinha and Ashworth (p. 237) on genetic recombination of *Dictyostelium discoideum.*

(ii) Cooney and Emerson (p. 243) on thermophilic fungi.

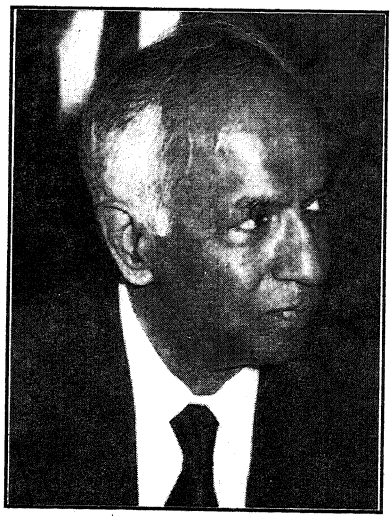
(iii) Garrison *et al.* (p. 243) on thermostability.

(iv) Schmitz and Srivastava (p. 204) on ultrastructure of *Laminaria groenlandica*, etc.

(v) LaRue and Narayanswami (p. 437, 440) on *Lunularia cruciata.*

(vi) Rai (p. 381) on carbon–nitrogen ratio on *Peltigera aphthosa, Platismatia* (misspelt Platimatia) *glauca* and *Pseudevernia* (misspelt Pseudoevernia) *furfuracea* (= *Evernia furfuracea*). None of the taxa is an Indian lichen.

(vii) Le Blanc and D. N. Rao and Le Blanc *et al.* (p. 382): work was done on Canadian lichens in relation to pollution in Canada.



There are a large number of misspelt words, including botanical names of plants; some of them may be due to the printer's devil, but others do not seem to be so.

The price is prohibitive.

Subrahmanyan Chandrasekhar

1910–1995

The news of Subrahmanyan Chandrasekhar's death on 21 August 1995 arrived as this issue of *Current Science* was going to the press. Chandrasekhar's passing marks the end of a glorious chapter in modern physics. Awarded the 1983 Nobel Prize, Chandrasekhar was one of the dominant figures of twentieth century astrophysics. A forthcoming issue of this journal will carry a detailed account of his scientific accomplishments.

Professor T. R. G.: An appreciation

T. R. Govindachari will shortly be turning 81 and would have seen a thousand moons. I had the privilege of being associated with him for over four-and-a-half decades, as a student in his intercollegiate lectures for B Sc (Honours) in chemistry (long since discontinued), as his first Ph D student and as a CSIR postdoctoral fellow at Presidency College, Madras, as a Departmental Head during his direction of CIBA Research Centre, Bombay, and then on as a fellow organic chemist. I meet him off and on in some symposium or the other, and when I am in Madras, I unfailingly visit him in the compact but well-equipped Centre for Agrochemical Research which he has organized for SPIC Science Foundation. These visits are invariably inspiring and I return wondering whether the country cannot find in his personality panaceas for many an ailment that afflict Indian science.

Some weeks ago I telephoned to him to say that I would be in Madras for a couple of days. He immediately insisted that I should visit him for discussing the affairs of the National Organic Symposium Trust (NOST), a nonprofit organization established by five of the country's seniormost organic chemists, S. Swaminathan, Nityanand, Sukh Dev, Bhattacharya and himself. The major activity of NOST is to promote Organic Chemistry in India by holding conferences (like Guha and Gordon) and to support other symposia from funds that he and the other founders had collected. He had come to Bombay in 1987 for a fund collection drive. He was then 72 and I still remember vividly how he went from one industrial house to another soliciting donations. His strenuous efforts and those of other founders finally gave NOST the income to organize the NOST conferences, which are done by the Council, with the Trustees (TRG being one of them) keeping themselves in the background. NOST is carrying on its mission quietly and with very little fanfare, but, like other acts of good faith, has some disbelievers. TRG shared his concerns with me during this last visit and discussed with me at length how real or perceived imperfections in the organization could be addressed.

Actually, when I stepped into his laboratory that day, I found him engrossed in deciphering an NMR spectrum along with an associate. He told me with his usual self-deprecatory smile how he was trying to inform himself of recent techniques in NMR spectroscopy so that these could be mobilized for structure elucidations. He also divulged to me with pride and satisfaction that he was able to persuade SPIC and DBT to fund a modest Supercon NMR for the Research Centre, and with mischief in his eyes, he showed me how he had converted one floor into two by building a mezzanine, thus effectively doubling the laboratory space, enabling both the research group and the sizeable array of sophisticated equipment to co-exist comfortably. True to his colours, TRG at 81 goes about his research activities, quietly keeping abreast with recent scientific developments and with the tools available to him, not cribbing at the lack of one or the other but silently working towards adding the necessary ones.

On an earlier visit, he had shown me with undisguised excitement, beautiful crystals of azadirachtin A (the now universally famous antifeedant principle present in the seed kernels of neem) and the results of single-crystal X-ray studies (*Current Science*, 1994, **66**, 295, 362). Formulations of crude neem extract containing 300–3000 ppm of azadirachtin A are marketed now in many countries as an eco-friendly pesticide. TRG's group has developed processes for obtaining azadirachtin-enriched neem extracts as well as formulations which are now distributed by SPIC Biotech. I would not be surprised if he had the purest sample of azadirachtin A in the world. TRG also mentioned to me how he had a few other leads from plant sources with pesticidal properties. In fact, for nearly six decades, TRG has brought in unparalleled perseverance, single-minded devotion and incisive chemical insight to the study of the vast flora of this country.

Over the years, his group has isolated many complex-structured compounds belonging to diverse classes of natural products such as alkaloids, oxygen heterocycles and terpenes, quite a few of them being the prototypes of a particular group, e.g. tylophorine, echitamine, kopsine, ancistrocladine (alkaloids) wedelolactone (furocoumarin) and cedrelone and ishwarone (terpenes). Some of them had potent biological activity (tylophorine – antiasthmatic; wedelolactone – hepatoprotective, ancistrocladine – potential anti-HIV). TRG and coworkers had located a very rich source of the anticancer alkaloid, camptothecin in an Indian plant, when only milligrams were available for clinical trials in USA. Currently, TRG's extensive work on neem has yielded many new congeners of azadirachtin A.

I have dealt at some length on TRG's contributions to natural-products chemistry because I feel that our young organic chemists can learn a lesson from it. Currently, there is a resurgence in this branch of chemistry, particularly as

a source of ecocompatible bioactive molecules serving as leads or ending up as drugs or plant protection chemicals. Taxol, artemisinin and azadirachtin are but three recent examples. Let us ask ourselves the following question: Can we do interesting and useful chemistry in this area doing justice to our plant wealth, or rather, should we pursue the fashions of the day in vogue elsewhere. There is no doubt that science is universal and knows no barriers, but why cannot we be trendsetters for a change?

An X-ray crystallographer of the Madras University Biophysics Department told me the other day that even now TRG himself comes to the department personally with samples for structure determination. So does he for special NMR and mass spectra. It is typical of him even past 80 to be in the laboratory every morning regularly at 9 a.m. and work till late in the evening – surely a trait worthy of emulation by the younger generation. His achievements after retirement from CIBA Research Centre in 1975, such as establishing two research centres, speak for his indefatigable energy and passion for science. Besides development of useful processes for synthetic molecules and extraction of natural products, TRG has added about 30 papers to his earlier tally of 274.

Looking back, TRG can be justifiably satisfied with what he has achieved during 45 years of professional career. As a Professor of Chemistry, Presidency College, Madras (1950–1962), he built up a school of research in natural-products chemistry (and that too with minimum available facilities) whose excellence has been acknowledged internationally. Simultaneously, he was acclaimed as a good teacher who ushered in an appreciation of modern theories of organic chemistry. For a year and a half (1961–1962), he also served as the Principal of Presidency college and might have well become the Director of Public Instruction. The next twelve-and-a-half years (1963–1975) saw him as the Director of Ciba Research Centre, which he moulded into an internationally known research centre and wherein he collected a group of the finest young scientists of the country to do basic research for the development of new drugs and dyestuffs. For a couple of years afterwards (1976–1978) he was a consultant to the Central Leather Research Institute, Madras. Later on he established a good R&D facility for Amruthanjan (1977–1986). He joined SPIC in 1987 as an adviser to their Science Foundation and set up the Centre for Agrochemical Research, wherein he continues his activities. In both these laboratories, TRG has been investigating natural products, in addition to guiding the groups in process development activities.

TRG's achievements have earned him several national recognitions (Bhatnagar Prize for Chemistry, Meghnad Saha Medal, Golden Jubilee Commemoration Medal, Fellowships of IASc and INSA) and international honours (Plenary lecture at the first IUPAC, National Products Symposium, Membership of the Bureau of IUPAC) but I firmly believe that many more should have accrued to him. He has been a President of the Indian Chemical Society but not of the prestigious Science Academies. I suspect that his long post-academic association with industry, especially with a multinational company, has been responsible for his name not appearing in the Indian Government's list of New Year Honours year after year. Shy by nature and reticent by disposition, TRG is not gregarious or garrulous and certainly not given to beating his own drums. It is a pity that his experience and expertise in matters pertaining to education and academic and industrial research, especially in new drug development, have not been adequately appreciated and sufficiently utilized by the scientific community. The loss is not his but of Indian science and that is another ailment that afflicts Indian science!

Eugene Paul Wigner – A tribute*

N. Mukunda

One of our last surviving links with the period of the creation and development of quantum mechanics was broken with the passing of Eugene Wigner on 1 January 1995 at Princeton in the USA. Wigner was remarkably talented and wide-ranging in his interests, and his work touched innumerable aspects of modern physics. In every area that he turned to, he discovered new and profound insights and interesting viewpoints, often understood and carried further by others much later. He was as much at home in fundamental problems of physics and their mathematical analysis as in engineering and technological matters. In this tribute, I shall first describe briefly his life and career, then turn to a sketch of his work, and conclude with an attempt to capture his personality and philosophy of science and life.

A brief life sketch[1]

Eugene Paul (Jeno Pal in Hungarian) Wigner was born on 17 November 1902 in Budapest, Hungary, to Elisabeth Einhorn and Anthony Wigner. He thus belonged to the same generation as Werner Heisenberg, Enrico Fermi and Paul Dirac. Leo Szilard and John von Neumann were Wigner's classmates at the Lutheran High School in Budapest – 'at that time, perhaps the best high school of Hungary and probably also one of the best of the world'[2]. Wigner retained great regard for his mathematics teacher L. Ratz, who also recognized and encouraged von Neumann's unusual talents.

After a year spent at the Technical Institute in Budapest, in 1921 Wigner joined the Technische Hochschule in Berlin to train as a chemical engineer. He completed his doctorate in 1925 and then worked for a year and a half as a leather chemist. By this time he had become very much a part of the Berlin physics scene; his break came with an appointment as assistant to Erwin Schrödinger (who had succeeded Max Planck at Berlin) for 1926–27. This was followed in 1927–28 by a position as assistant to Max Born in Göttingen, and then as Privatdozent at Göttingen during 1928–30. At this point he moved to the United States, where he spent the rest of his life.

Wigner's career in the US began as a lecturer in mathematical physics during 1930 at Princeton University, quickly elevated to a Professorship from 1930 to 1936. The year 1937–38 was spent as a professor at the University of Wisconsin at Madison. Upon return to Princeton, he became Thomas D. Jones Professor of Mathematical Physics in 1938, a position he held until 1971. The academic year 1957–58 was spent at Leiden in the Netherlands.

In 1937 Wigner became a naturalized citizen of the United States. He took his citizenship very seriously, and played a very active role in public affairs and matters of government policy. As his contribution to the war effort, he spent 1942–45 at the Metallurgical Laboratory of the University of Chicago, the last two years as the head of the theory group there. Earlier he had joined Szilard and Fermi in persuading Einstein to write the famous August 1939 letter to President Franklin Roosevelt that led to the setting up of the Manhattan Project. He was present at the University of Chicago's Stagg Field Squash Courts on 2 December 1942 to witness the world's first controlled nuclear fission reaction set up under Fermi's leadership. During 1946–47 he served as Director of what later became the Oak Ridge National Laboratory in Tennessee. In 1952 he was full-time adviser to the Du Pont Company to design the Savannah River heavy-water plutonium production reactors. Soon after, in 1954 he was appointed to the General Advisory Committee of the United States Atomic Energy Commission, and served also on many panels of the Science Advisory Committee to the President of the United States.

Of the many awards that came to Wigner, we must mention the Medal for Merit, the Franklin Medal for 1950, the Enrico Fermi Award of the USAEC for 1958, the Atoms for Peace Award for 1960, the Max Planck Medal for 1961, and the 1963 Nobel Prize in physics (shared with Maria Mayer and Hans Jensen) for his wide range of contributions to quantum mechanics.

Wigner's first marriage, to Amelia Franck in 1936, was followed by a second one in 1941 to Mary Annette Wheeler, a professor of physics. His sister Margit Balasz nee Wigner married Paul Dirac in 1937. It appears that Dirac was so shy that he once introduced his wife to an old friend as Wigner's sister. In response (!) Wigner referred to Dirac as 'my famous brother-in-law'[3]. There is a charming account by Margit of her first meeting with Dirac in Wigner's company. At a meeting in Budapest, the von Neumanns had invited Margit to visit and stay with them in Princeton. And then[4]:

'Eugene insisted, "If you come to Princeton, you must stay with me. What would people say if you did not stay with your brother?" I was not terribly thrilled with the idea. The von Neumanns had a lovely home,..., while my brother liked to appear, and act, like a pauper. We sailed in the fall; Eugene had a two-bedroom apartment, proudly boasting that he furnished it to the cost of under $25. It looked like it ... It was soon after my arrival; we were having lunch at one of these restaurants, when a tall, slender young man entered the dining room, looked at Eugene and

*Text of special colloquium given at Raman Research Institute, Bangalore on June 16, 1995.

greeted him. He looked lost, and sad. I asked who he was, still standing undecided and none too happy-looking. I was told, he was an English physicist, whom Eugene knew in Göttingen, where they used to have their meals together. "He does not like to eat alone". "So why don't you ask him to join us?" That was how I met Paul Dirac. That was the fall of 1934. The Institute for Advanced Studies had no building of its own as yet. Its members, like Einstein, von Neumann and Dirac as a visiting member, had adjoining rooms in a large university building, called Fine Hall. I remember so well: to the left was Einstein's room, in the middle Eugene's and to the right of him, Dirac's.'

Wigner, Szilard and von Neumann formed the famous Hungarian trio who contributed so decisively to intellectual life in the United States in the 1930s and later. There is a story that during a meeting of scientists connected with the war effort there was so much confusion due to many languages being used that someone got up and exclaimed: 'Gentlemen, let us use one language we can all understand – Hungarian!'

When Wigner died he left behind his third wife Eileen, a son and two daughters.

Contributions to science and engineering

Wigner's work in physics is characterized by hard mathematical analysis based on simple yet profound physical assumptions. While there is a down-to-earth practical quality to some of his work, in others he dealt with the most fundamental issues with great refinement – he was both an artist and an engineer, and quantum mechanics was his medium. To quote John A. Wheeler[5]: 'In the work of Eugene Wigner one sees the basic harmony between the conceptual framework of physics and the structure of the mathematics associated with that physics.' On the other hand, his grasp of technology is best conveyed by this passage from Lawrence Dresner and Alvin M. Weinberg[6]: '.... the facility with which he could pass back and forth between engineering and physics – from a discussion of the probable distribution of energy levels in U^{235} to a critical examination of the blueprints of the concrete foundations for the Hanford reactors, or from a group theoretical argument in transport theory to the design of aluminium fuel elements!'

Wigner's first important work in physics, completed during his apprenticeship with Schrödinger, was a powerful treatment of quantum many-fermion systems. Around the time of the move to Göttingen, and following a suggestion by von Neumann, he undertook the major task of introducing group-theoretical methods into quantum mechanics. By 1928 he had published six landmark papers on the subject; he shares with Hermann Weyl the credit for making this an essential and characteristic component of quantum physics which pervades all its applications. During the 1930s he worked in solid-state physics and at the frontiers of the developing subject of nuclear physics, making a major effort to understand the forces between nucleons, and developing the compound nucleus model to explain resonance phenomena in neutron-induced nuclear reactions. His development later of the R-matrix theory of nuclear reactions was a response to a comment by Fermi that the compound nucleus model needed a firm theoretical foundation. Probably his most remarkable work in mathematical physics – the study of the unitary representations of the inhomogeneous Lorentz group – grew out of a suggestion made to him by Dirac in 1928. This was completed in Madison in 1937, and subsequently became the basic framework for all relativistic quantum theories. He came back to problems of nuclear structure in his supermultiplet theory of 1937, and later in his statistical treatment of nuclear spectroscopy based on random matrices.

In the midst of all this, in the 1940s he worked on the theory of neutron chain reactors and the design of plutonium breeder reactors.

Wigner's concern with the structure of quantum mechanics has led to a series of incisive insights over many years. In the early 1960s he turned to problems of interpretation and epistemology raised by the standard interpretation of quantum mechanics. At this point it is convenient to present briefly and selectively sketches of Wigner's work under several broad areas. This is admittedly an inadequate, incomplete and possibly superficial way to survey his work, yet it may succeed in conveying some idea of the range and magnitude of his achievements. Before embarking on this, we may recall the following important books published by Wigner: (1) *Group Theory and its Application to the Quantum Mechanics of Atomic Spectra* (Academic Press, New York, 1959; the original German version published by Friedrich Vieweg, Braunschweig, 1931); (2) *Nuclear Structure*, with Leonard Eisenbud (Princeton University Press, 1958); (3) *The Physical Theory of Neutron Chain Reactors*, with Alvin M. Weinberg (University of Chicago Press, 1958); and (4) *Symmetries and Reflections – Scientific Essays* (Indiana University Press, 1967). We may also mention that the October 1962 issue of the *Reviews of Modern Physics*, published on the occasion of his 60th birthday, contains many articles surveying Wigner's work in several areas.

Structure and content of quantum mechanics

Any serious user of quantum mechanics is sure to find herself employing repeatedly, either explicitly or implicitly, one or another of the many basic concepts and methods invented by Wigner. One of the earliest is the concept of parity[7]. In classical physics, space inversion is merely a geometrical operation or transformation, a rule to map each point in space to its image by inversion through a chosen origin. The time is left unaffected. A particle trajectory, for example, would be mapped on to another possible trajectory.

Classical space inversion:

$$P: x \to -x, t \to t,$$

$$x(t) \to -x(t).$$

Wigner showed that in quantum mechanics, parity is more than a transformation, it is a physical observable whose value can be experimentally measured. The possible results of measurement are ± 1, and the corresponding quantum states are said to possess even or odd parity, respectively.

Quantum space inversion:

$$P\psi(x,t) = \psi(-x,t),$$

$$\psi(-x,t) = \pm\psi(x,t) \Rightarrow P = \pm 1,$$

even/odd states.

It was this role of parity in quantum mechanics that was shown by Wigner to be the explanation for Laporte's selec-

tion rule in atomic spectroscopy[8]: the matrix elements of the electric dipole moment operator, and hence the corresponding transitions, vanish unless the two concerned states have opposite parities.

The deep connection between invariance principles and conservation laws, both in classical physics and in the quantum domain with specifically new and subtle features, remained a lifelong concern for Wigner, something he came back to time and again. In the particular case of rotational symmetry, the general programme of incorporating group-theoretical methods into quantum mechanics led to Wigner's impressive body of results concerning angular momentum in quantum mechanics[9]. The detailed representation theory of the rotation group SO(3) and its covering group SU(2), which is basic to quantum mechanics, was developed by him in a form suited to practical application. The angular momentum addition theorem, the concept of tensor operators, the Wigner–Eckart theorem for their matrix elements, explicit expressions for the Clebsch–Gordan coupling coefficients (also called the Wigner $3j$ symbols), leading on to the intricate Racah–Wigner calculus for coupling of tensor operators and computing the resulting matrix elements, the generalizations to other symmetry groups – all these oh-so familiar tools of the trade in atomic, nuclear and particle physics originate from his work.

In his book on group theory, Wigner formulated and proved a fundamental theorem concerning the representation of symmetry operations in quantum mechanics[10]. This is a very deep and subtle result, and a brief explanation would not be out of place. The relation between physical states and wave functions (or Hilbert space state vectors) in quantum mechanics is one-to-many. This is because a change in the overall phase of a wave function is physically unobservable:

$$\text{vectors } \psi, e^{i\alpha}\psi, e^{i\beta}\psi, \ldots \rightarrow \text{same physical state,}$$

$$\text{vectors} \xleftrightarrow{\text{Many-to-one}} \text{physical states.}$$

Therefore, what physical states correspond to in a one-to-one manner are not vectors but rays: a ray is an equivalence class of vectors, two vectors being declared equivalent if they differ only by a phase. The ray to which a vector ψ belongs can be unambiguously described by the corresponding projection operator or density matrix ρ_ψ:

$$\text{vector } \psi \rightarrow \text{ray } \rho_\psi = \psi\psi^+,$$

$$\text{rays} \xleftrightarrow{\text{one-to-one}} \text{physical states.}$$

Rays do not form a vector space, so their geometry is somewhat harder to visualize than that of vectors ψ. Wigner's theorem then shows that any mapping $\mathcal{T}$ of rays (i.e. physical states) onto themselves preserving quantum-mechanical probabilities – and any symmetry operation must be of such a nature – can be 'lifted' to either a linear unitary or an antilinear unitary (antiunitary) transformation T on vectors.

Unitary–antiunitary theorem:

Symmetry operation $\mathcal{T}$,

$\rho_\psi = \psi\psi^\dagger \rightarrow \mathcal{T}(\rho_\psi) = \rho_{\psi'} = \psi'\psi'^\dagger$

$\rho_\varphi = \varphi\varphi^\dagger \rightarrow \mathcal{T}(\rho_\varphi) = \rho_{\varphi'} = \varphi'\varphi'^\dagger$

$\psi', \varphi', \ldots$ determined up to phases,

$|(\varphi', \psi')| = |(\varphi, \psi)| \Rightarrow$

either

$\psi' = T\psi, \varphi' = T\varphi, \ldots,$

T linear unitary,

$(\varphi', \psi') = (\varphi, \psi) \rightarrow$ unitary alternative;

or

$\psi' = T\psi, \varphi' = T\varphi, \ldots,$

T antilinear unitary,

$(\varphi', \psi') = (\varphi, \psi)^*$

$= (\psi, \varphi) \rightarrow$ antiunitary alternative.

(Here the inner product of the Hilbert space vectors φ, ψ is denoted by (φ, ψ)). This remarkable theorem has been extended and proved under different conditions by others over the decades.

Most symmetries in quantum mechanics turn out to be of the unitary type; time reversal is one example where the antiunitary alternative is realized. The analysis of this transformation in quantum mechanics was given by Wigner[11] in 1932. In Schrödinger's quantum mechanics, time reversal acts on wave functions thus:

$$T\psi(x, t) = \psi(x, -t)^*.$$

Unlike parity, however, this operation does not have the status of a physical observable in quantum mechanics, and its eigenvalues are not invariantly defined and are not experimentally measurable.

Continuing with the theme of symmetry in quantum mechanics, Wigner and von Neumann proved a very interesting result in 1929, which is of great importance especially in molecular physics[12]: if the electronic states in a molecule are classified according to their symmetry, i.e. the representation of the full group of symmetry of the relevant molecule, and if we have two distinct eigenvalues and eigenstates sharing the same symmetry (two electron terms), these eigenvalues will not cross (become accidentally equal) as one varies the internuclear distances in the molecule. On the other hand, electron terms of distinct symmetry can cross. This is a general theorem of quantum mechanics, applicable to a generic hamiltonian possessing some symmetries and dependent on a continuous parameter: as the parameter is varied, distinct eigenvalues 'of the same symmetry' will not accidentally cross but will repel each other.

Many years later, Wick, Wightman and Wigner[13] brought to light another aspect of symmetry in quantum mechanics, namely the existence of superselection rules. This amounts to a restriction on the applicability of the superposition principle in quantum mechanics. In general, the Hilbert space of states of a quantum system breaks up into sectors, and the formation of complex linear combinations to produce new states from old is limited to one sector at a time, not cutting across sectors. This is the reason why the phase of a spinor field – a field with half odd integer spin – is nonobservable. So, for instance a nontrivial linear combination of states with integer and half odd integer angular momenta cannot be prepared. As another example, one finds that linear superpositions of states of distinct electric charge are unphysical. It is suspected that these results had long been known to Wigner, and he was persuaded by his coauthors to join them and say so in print.

In the preface to his book on group theory, Wigner relates a conversation with von Laue on the use of group theory as the natural tool with which to tackle problems in quantum mechanics[14]. He says: 'I like to recall his question as to which results ... I considered most important. My answer was that the explanation of Laporte's rule (the concept of parity) and the quantum theory of the vector addition model appeared to

me most significant. Since that time, I have come to agree with his answer that the recognition that almost all rules of spectroscopy follow from the symmetry of the problem is the most remarkable result'.

The exponential decay law for unstable states has been well known since the days of Rutherford's experiments on radioactivity. The first properly quantum-mechanical discussion and derivation of this law is due to Weisskopf and Wigner[15]. They were able to provide the basic theory for the natural linewidths and lifetimes of atomic states decaying via transitions to other states with emission of radiation. Their use of second-order perturbation theory along with judicious and delicate assumptions also disclosed that the exponential decay law is only an approximate, not an exact, consequence of quantum mechanics; so departures from it for both very short and very long times are to be expected.

The linear superposition principle of quantum mechanics, already referred to above, finds its most natural expression at the level of state vectors in Hilbert space. The ray space or density matrix description of physical states, which is closer to a classical description, obscures this principle somewhat – it is present but not manifest. In 1932, while studying thermodynamic equilibrium in quantum mechanics, Wigner introduced another description of states for quantum systems possessing classical canonical analogues[16]. Thus, each quantum state is describable by a certain real distribution or function on the classical phase space. In one dimension with classical phase space variables x and p, the construction is as follows:

$$\psi(x) \to W(x,p) = \frac{1}{h}\int_{-\infty}^{\infty} \mathrm{d}x' \; \psi\left(x-\frac{1}{2}x'\right)\psi\left(x+\frac{1}{2}x'\right)^{*} \exp(\mathrm{i}x'p/\hbar)$$

These distributions – named after Wigner – are at the level of density matrices, not state vectors. They are suggestively like classical probability distributions on phase space, such as one uses in classical statistical mechanics. However, since in general $W(x, p)$ can become negative for some arguments, we do not have a classical statistical picture with well-defined probabilities. This is as it should be, since quantum features must be preserved. This description of states in quantum mechanics turned out to be the counter-part, or companion, to a rule or convention given by Weyl for associating a quantum-mechanical operator with every classical dynamical variable; and these ideas were further extended, particularly by Moyal[17].

Wigner contributed a great deal to the formal description of scattering and reaction processes in quantum mechanics, especially in the context of nuclear physics. One of his results concerns the physical meaning of phase shifts. In general, scattering cross-sections are determined by the squared magnitudes of S-matrix elements, and in these the phases get washed out. On the other hand, the spatiotemporal development of a scattering process described within the limits set by quantum mechanics, involves these phases. The beautiful connection found by Wigner is the expression for time delay caused by interaction and its relation to the energy dependence of the scattering phase shift[18]:

$$\Delta T(E) = 2\frac{\mathrm{d}}{\mathrm{d}E}\delta(E)$$

Here $\delta(E)$ is the phase shift at energy E; thus, an attractive (repulsive) interaction leads to $\delta(E)$ increasing (decreasing) with energy, hence to a delay (advance) in the appearance of the final-state products of a collision after undergoing interaction.

We conclude this account with a couple of 'curios'. Classically, one expects the possible states of a system of interacting particles – especially, a two-body system – to separate into two types: unbounded or scattering states, having positive energy, and bound states, having negative energy. In quantum mechanics we expect the energy eigenvalues to behave analogously: a continuum of unbound, positive-energy scattering states sitting on top of a set of discrete negative-energy, bound states. Only the latter have normalizable wave functions. In a remarkable paper in 1929, Wigner and von Neumann produced an example of a two-body potential which possesses a bound state embedded in the continuum[19]! This is an unexpected and essentially quantum-mechanical result. The potential is 'artificial' in that it has to be carefully engineered to produce the desired result, and the state involved is unstable even under small perturbations.

The passage from classical to quantum mechanics results, at the level of dynamical variables, in the loss of *commutativity* in multiplication. Thus, for two physical quantities represented by operators A and B, in general $AB \neq BA$. However, this departure from the classical is limited in the sense that *associativity* is maintained: for three (or more) quantities multiplied in a given sequence the product is unambiguous: $(AB)C = A(BC) = ABC$. One can ask how quantum mechanics might be modified if one takes the nonclassical path one step further and, along with commutativity, one gives up associativity as well. This was examined by Jordan, von Neumann and Wigner[20] in 1934 . It did not, however, lead to any alternatives with sufficiently interesting and flexible properties to give a further extension of quantum mechanics.

Going over this rich list of contributions, one is tempted to say that Wigner took his revenge for not having been involved in the discovery of quantum mechanics, and compensated for it accordingly!

Nuclear forces, structure and reactions

Following the discovery of the neutron by Chadwick in 1932, there was a great deal of work exploring the nature of the strong nuclear forces between neutrons and protons. It was realized that these would be strikingly different from the familiar Coulomb forces between protons, of very short range, and with complicated distance dependences. Further dependences on spin and space exchange were also anticipated. Wigner was one of the earliest contributors to this field, and his name is associated with one of the four basic types of terms in the potential energy expression[21]:

potential energy between proton and neutron =

purely distance-dependent Wigner term +
spin exchange Bartlett term +
space exchange Majorana term +
spin and space exchange Heisenberg term.

Thus, the Wigner force is the simplest of all; the others either distinguish between singlet and triplet spin states, or between even and odd orbital angular momenta, or both. Such phenomenological potentials are useful in analysing low-energy nuclear bound states, scattering processes, etc.

The low-energy (in the keV to few MeV range) scattering cross-sections of neutrons off various nuclei were experimentally studied by Fermi and his collaborators, and many other groups, around 1936. They found striking resonance structures in these cross-sections, with sharp maxima separated by very small values in between. Soon after, a theoretical explanation was offered independently by Niels Bohr on the one hand, and by Gregory Breit and Wigner[22] on the other. This is the so-called compound nucleus model. It pictures the scattering and reaction processes as taking place in two steps. At first the incoming low-energy projectile (which could be some light nucleus rather than a neutron) and the target combine to produce a compound nucleus in one of several possible metastable states. In this process the projectile energy is quickly shared with all the nucleons in the compound structure, and then the mode of formation of this structure is 'forgotten'. In the second step, the decay of the compound nuclear state into various energetically allowed channels is governed by probability laws. It is the probability of occurrence of the first step that shows an extremely sensitive energy dependence and gives rise to the observed resonances. In their work Breit and Wigner derived the famous bell-shaped single-level resonance formula known after their names:

Probability of formation of compound nucleus

$$\alpha\Gamma_\lambda / \{(E - E_\lambda)^2 + \tfrac{1}{4}\Gamma_\lambda^2\},$$

E = total initial energy,

$E_\lambda, \Gamma_\lambda$ = average energy, width, of compound nuclear state λ.

The partial cross-sections for subsequent decays into each of the several available final channels retain this characteristic energy dependence.

Sometime after this, around 1944, Fermi remarked to Wigner (as was mentioned earlier) that a good theoretical basis for the compound nucleus model was lacking. Thereupon Wigner set about formulating one. This was the starting point of the R-matrix theory of nuclear reactions, developed by him largely in collaboration with Eisenbud[23]. The basic idea is to separate the total multidimensional configuration space of all the nucleons in the compound nucleus (i.e. the projectile nucleons plus the target nucleons) into two parts: an interior region where they are *all* within the range of nuclear forces acting between every pair, and an exterior region where this is not so. In the latter region, one then defines or picks out essentially nonoverlapping subregions, one for each possible (two-body) final channel into which the compound nucleus can decay. Instead of posing a multichannel hamiltonian eigenfunction and eigenvalue problem, a series of matching conditions connecting the interior and exterior channel wave functions and their radial derivatives, across the borders between the interior and each exterior region, are set up. The R-matrix elements are quantities that enter these relations, they are a multichannel generalization of the logarithmic derivative of a wave function in a one-dimensional radial problem. The parameters entering the R-matrix are the energy values and the various partial decay widths of all possible compound nucleus levels. Thus, the R-matrix became simultaneously a convenient method for parametrization of scattering and reaction amplitudes using phenomenologically accessible compound nuclear state energies and widths, and with further developments, a way to embody general physical principles, such as unitarity and causality, governing reaction processes. *Inter alia* this led to a multilevel generalization of the Breit–Wigner resonance expression given above, and to a criterion for the validity of the single-level formula.

Returning to the problem of nuclear forces and structure, in 1937 Wigner came up with the SU(4) supermultiplet theory to systematize the low-lying energy levels of light nuclei[24]. The idea was that the interactions among protons and neutrons, regarded as nucleons possessing the isospin degree of freedom introduced by Heisenberg[25] as early as 1932, might to a good approximation be both spin- and isospin-independent. More generally, it might be invariant under all four-dimensional unitary transformations mixing up the four independent spin–isospin states of a nucleon. (This assumption actually leads to specific spin and isospin dependences in the interaction.) It would then be possible to arrange the energy levels of 'neighbouring' nuclei with a common mass number into various unitary irreducible representations (UIRs) of SU(4), consider systematically the breaking of this symmetry, etc. Each UIR of SU(4) is made up of several spin–isospin multiplets in a definite way. While the idea was physically well motivated as a useful first approximation, it was pursued only to a limited extent. However, many years later, in 1964, Wigner's theory provided the inspiration for a similar SU(6) invariant theory of baryons and mesons in the framework of the quark model [26].

At the other end of the scale from low-lying well-separated energy levels of light nuclei, we have the relatively highly excited and closely spaced levels of heavy nuclei with many degrees of freedom. Here Wigner proposed a completely different physical approach, one which has stimulated work by many others and led to connections with several other problems[27]. The physical ideas may be motivated as follows. As the excitation energy (of a complicated nucleus) increases, one expects the energy levels to get closer and closer, and one also loses hope of being able to obtain them individually from a first-principles Hamiltonian. Instead, what would be more accessible and physically interesting are various statistical properties of the levels; the probability distributions for successive levels to occur at various energies, for the spacing between neighbouring levels to have different values, and so on. To obtain these statistical features, and at the same time to reflect the fact that one is dealing with a very complex system with many degrees of freedom, Wigner proposed that the basic Hamiltonian (after truncation to a large but finite dimension) be itself regarded as a random matrix, belonging to an ensemble with specified properties. Once one specifies the nature of this ensemble, regarded as a primary input, the statistical properties of the eigenvalues of the Hamiltonian, the spacing distribution, etc., can all be derived, in principle, as secondary consequences. It turns out that in using this approach one must deal with one 'simple sequence' of nuclear levels at a time; this is a set of levels possessing the same exactly conserved quantum numbers – 'belonging to the same symmetry'– such as the total angular momentum and parity. Properties of different simple sequences are independent. Thus, Wigner's hypothesis was that the local statistical behaviour of the levels in a simple sequence is given by the properties of the eigenvalue spectrum of a random matrix drawn from a suitable ensemble. The type of ensemble to be used depends on the integer or

half odd integer nature of the total angular momentum, behaviour under time reversal, and presence or absence of rotational symmetry. Later work has shown that there are three natural types of ensembles, in correspondence with the three great families of classical compact simple Lie groups: the Gaussian real orthogonal, the Gaussian complex unitary, and the Gaussian symplectic ensembles. These ensembles consist respectively of real symmetric, complex hermitian and real quaternionic matrices (of suitable dimensions, even in the last case). The probability distribution defining the ensemble is invariant under a real orthogonal, complex unitary or unitary symplectic group of transformations applied to its elements; moreover, the matrix elements of the Hamiltonian are assumed to be independent random variables. It is the combination of these two properties that makes these ensembles Gaussian.

A great deal of sophisticated mathematical analysis has gone into these objects, and this activity continues[28]. One very interesting feature that was recognized very early was that the spacing distribution vanishes as a power of the spacing as the spacing tends to zero. The rate of this vanishing, the power involved, is characteristic for each of the three families of ensembles. The physical meaning of this result – borne out by experiments and reminding us of the no-crossing theorem of Wigner and von Neumann for electron terms of the same symmetry – is that within a simple sequence neighbouring levels do not like to come very close to one another. Had we imagined that the energy levels themselves were independently statistically distributed, there would have been no cause for such level repulsion. This only emphasizes Wigner's idea that the properties of the ensemble of Hamiltonians must be chosen first, and other properties then obtained as consequences.

Quantum field theory, relativistic classical and quantum mechanics

The rules for canonical quantization – creating a quantum theory from a classical one – were originally invented in the context of nonrelativistic particle quantum mechanics. The first successful application of these rules to a classical field theory came with Dirac's quantization of the electromagnetic field. This led to his classic 1927 paper in which he treated the processes of emission and absorption of radiation by matter, using quantum principles and the photon concept[29]. The quantized field led to a synthesis of complementary classical particle and field languages, and could describe states with variable numbers of identical particles. The canonical quantization method led to commutation relations of the form

$$a_r a_s^\dagger - a_s^\dagger a_r = \delta_{rs},$$

$$a_r a_s - a_s a_r = a_r^\dagger a_s^\dagger - a_s^\dagger a_r^\dagger = 0.$$

Here a_r ($a_r^\dagger$) are the annihilation (creation) operators for photons in various states indexed by r. These states are an independent, orthogonal and complete set of modes of the electromagnetic field. The operators a_r, $a_r^\dagger$ are quantum analogues of the classical complex coefficients in an expansion of the classical field in these modes. In this case the appearance of commutation relations led naturally to Bose–Einstein statistics for photons. Very soon after Dirac's paper, Jordan and Wigner showed that to describe fermions (such as electrons) obeying Pauli's exclusion principle and Fermi–Dirac statistics, the particle annihilation and creation operators must obey anticommutation relations[30]:

$$a_r a_s^\dagger + a_s^\dagger a_r = \delta_{rs},$$

$$a_r a_s + a_s a_r = a_r^\dagger a_s^\dagger + a_s^\dagger a_r^\dagger = 0.$$

For a finite number of modes, they proved that up to equivalence there is only one irreducible representation of these relations, and it is finite-dimensional. This uniqueness is similar to a corresponding result in the case of commutation relations. The major difference is that from a mathematical point of view systems of operators obeying the anticommutation relations are quite 'harmless', while in the case of commutation relations they are unbounded and the space is infinite-dimensional – even for a finite number of modes. Of course, in the Jordan–Wigner case there is no sensible classical limit.

It is interesting to note that Dirac's initial reaction to this work of Jordan and Wigner was decidedly negative[31]. Wigner later attributed this to Dirac's being very committed to the Hamiltonian point of view in dynamics – 'a captive of the Hamiltonian formalism'. However, it became clear very soon that this was the correct way to set up quantum field theory for fermions, and it became part of the foundations of the subject.

The first attempts at uniting quantum mechanics and special relativity were due to Klein and Gordon. This resulted in the wave equation named after them, but it faced problems of interpretation at the one-particle level. The next, spectacularly successful, attempt was Dirac's work in 1928 that led to his wave equation for the electron and its series of amazing consequences[32]. Probably soon after, in 1928 itself, Dirac suggested to Wigner a comprehensive study of all possible unitary irreducible representations of the inhomogeneous Lorentz group (IHLG), i.e. of the homogeneous Lorentz group (HLG) supplemented by space–time translations. By about 1932, Majorana had constructed many of these UIRs, and later these were simplified by Dirac and Proca[33]. The solution of this problem posed by Dirac to Wigner became a herculean effort, being completed only in 1937. The result was an all-time classic paper in mathematical physics[34]. In it, Wigner acknowledges the help and guidance he received not only from Dirac but also on mathematical aspects from von Neumann. At some stage Dirac advised Wigner to be careful, and the latter replied[35]: 'You point out that care is needed in the analysis of the representations of the Lorentz group; I promise you that I will be careful'.

Wigner's paper contains a detailed analysis of the structure of the HLG and the IHLG, and of general unitary representations (URs) of the IHLG in the context of quantum mechanics; it then turns to a study of the UIRs. The result was that these could be classified into four broad types, depending upon the nature of the possible values of energy–momentum p^μ occurring within the UIR, and the allowed 'states of polarization' for each energy–momentum. The helicity λ is defined as the component of angular momentum in the direction of momentum. For each kind of p^μ (provided it is not identically vanishing) the allowed values of λ are determined by some UIR of a corresponding subgroup of the HLG, the so-called 'little-group' for that p^μ; it consists of all elements of the HLG which leave p^μ invariant. The pattern of UIRs

Table 1. The pattern of UIRs of the IHLG

Nature of p^μ	Little group within HLG(SL(2,C))	Number of polarization states, spectrum of λ	Remarks
(a) Time-like (positive or negative)	SO(3)(SU(2))	$2s+1$ for $s = 0, 1/2, 1 \ldots$ $\lambda = s, s-1, \ldots, -s$	Massive particles with zero or finite spin $s = 0$ for π meson $s = 1/2$ for electron
(b) Light-like positive or negative)	E(2), two-dimensional Euclidean group	One: $\lambda = 0$ Two: $\lambda = \pm s$, $s = 1/2, 1, \ldots$ Infinite: $\lambda = 0, \pm 1 \pm 2, \ldots$ or $\lambda = \pm 1/2, \pm 3/2, \ldots$	No known particles $s = 1$ for photons $s = 1/2$, $\lambda = -1/2$ for neutrinos No known particles
(c) Space-like	SO(2,1) (SL(2,R))	One: $\lambda = 0$ Infinite: $\lambda = s, s+1, \ldots$ or $-s, -s-1, \ldots$ $s = 1/2, 1, \ldots$ or $\lambda = 0, \pm 1, \pm 2, \ldots$ or $\lambda = \pm 1/2, \pm 3/2, \ldots$	Imaginary mass, unphysical
(d) Vanishing	HLG(SL(2, C))	–	–

of the IHLG is displayed in Table 1 (here space inversion or parity has been included in the HLG, except that for neutrinos this operation is undefined)[36].

While many of these UIRs were known earlier to Majorana and Dirac, the so-called infinite-spin or continuous-spin representations in cases (b) and (c) were genuinely new. In his work, Wigner did not carry the investigation of these, or of case (d), to completion. He mentioned their existence, and only remarked: '... the last case may be the most interesting from the mathematical point of view. I hope to return to it in another paper. I did not succeed so far in giving a complete discussion of the 3rd class.' Wigner's 'last case' and '3rd class' correspond respectively to (c) and (d) in our table. We also see that not every mathematically acceptable UIR of the IHLG is acceptable on physical grounds.

Relativistic quantum systems described by any UIR of the IHLG are called 'elementary systems'. Truly elementary particles, able to exist in isolation, are described using them. Examples are photons, neutrinos, electrons and muons. The phrase 'elementary systems' conveys the meaning that all their properties are revealed by studying their behaviour under all elements of the IHLG – there is no internal structure involved. In the above listing, only cases (a) and (b) for finite helicity are realized in nature.

The UIRs of case (d) are actually UIRs of the HLG SO (3,1) (or of the closely related group SL *(2, C)*). It remained for Harish-Chandra and for Gel'fand and Naimark to determine them independently[37]. The inputs needed to construct the UIRs of case (c) for infinite spin were provided by Bargmann through his construction of the UIRs of SO (2,1) and SL $(2,R)$[38].

In his contribution to RMP, Dirac made the following comments on Wigner's work[39]. 'The problem of working out all unitary representations of the IHLG has been dealt with by Wigner, taking the mathematical point of view that two representations are equivalent if they are connected by a unitary transformation. He decomposes the representations into their irreducible constituents and finds that the irreducible constituents provide theories of elementary particles with various spins. This work does not lead to any interaction between particles. To bring in interaction, one must depart from the point of view of looking at two representations as equivalent if they are connected by a unitary transformation, a point of view which involves looking upon all unitary transformations as trivial. To a physicist, some unitary transformations are trivial, whereas others (for example, the S matrix) are far from trivial, so a physicist cannot look upon two representations connected by a unitary transformation as necessarily equivalent.' The point is that for any really interesting relativistic quantum system, such as a relativistic quantum field theory, it is not only important to know which UIRs of the IHLG are present, but also how they are put together. However it must be pointed out that as early as 1949 Wigner himself had drawn attention to this situation[40]: 'The elementary systems correspond mathematically to irreducible representations of the Lorentz group and as such can be enumerated... However, in the description by irreducible states, the form of almost all physically important operators remains unknown and, in fact, depends on the system, the types of interactions, etc. This leads to a rather strange dilemma: in the customary description the form of the physically important operators is known but the time dependence of the states is unpredictable or difficult to calculate. In the description just mentioned, the situation is opposite: the time dependence of the

states follows from the invariance properties, but the form of the physically important operators is hard to establish.'

Wigner returned on many occasions to a description of the results of his classic work. He also constructed with Bargmann a unified set of wave equations whose solutions would lead to UIRs of types (a) and (b) in our table[41]. His work with Newton on the problem of position is particularly interesting, so I describe it in a little detail [42].

The starting point of nonrelativistic particle quantum mechanics is the set of positions and momenta as primary dynamical variables, out of which all other variables are built up. (Later work has shown that these positions and momenta can be derived as secondary objects starting from suitable quantum-mechanical representations of the Galilei group). Now, from Wigner's point of view in the relativistic context, the primary things are the UIRs of the IHLG. After having set them up, one must examine within which UIRs one can construct position operators with physically desirable properties. Such an analysis was first undertaken by Newton and Wigner. They were able to show that in every finite mass and finite spin UIR (case (a)) a unique set of position operators possessing several physically reasonable properties does indeed exist. However, contrary to naive expectation, they do not form the space components of a relativistic four-vector. This illustrates the fact that in quantum theory the unitary transformation law is more basic than the geometric one or manifest covariance. In the massless case with finite nonzero helicity even this much cannot be done. Thus, neither photons nor neutrinos can be localized in space.

In other related work we mention the study by Inonu and Wigner of the process of 'group contraction' by which the IHLG goes over in the nonrelativistic limit to the Galilei group[43]; Salecker and Wigner's analysis of deep conceptual problems in bringing together quantum mechanics and general relativity, caused by quantum limitations on position measurements[44]; and van Dam and Wigner's construction of classical relativistic direct-interaction theories resting upon integrodifferential equations for particle trajectories[45]. One of Wigner's conclusions was that while special relativity and quantum mechanics could at least conceptually be combined, with general relativity and quantum mechanics there was no common ground at all.

Interpretation of quantum mechanics

In the early 1960s Wigner turned to a serious examination of the problems of interpretation of quantum mechanics, and a clear expression of the orthodox position which essentially coincided with his own[46]. As evidence for the latter, here is his own statement: 'The orthodox view is very specific in its epistemological implications ... A large group of physicists finds it difficult to accept these conclusions and, even though this does not apply to the present writer, he admits that the far-reaching nature of the epistemological conclusions makes one uneasy.' He also often said that he was adding hardly anything new to London and Bauer's classic 1939 exposition[47]. He accepted the treatment of measurement theory that had been articulated by his friend von Neumann[48] as early as 1932, and wanted to restate it for a new generation and extract its ultimate consequences for epistemology.

Wigner emphasized that the state vector of a quantum system changes in two mutually exclusive ways – continuous, deterministic Schrödinger evolution when not subject to observation, and discontinuous, probabilistic, collapse when measurements are made. He went to much length to show that the linear Schrödinger equation – even including the apparatus and the system's coupling to it – can never produce the macroscopically desired collapse phenomenon, and stressed repeatedly that pure states and mixtures have very different physical properties. He also presented a pragmatic answer to the question 'What is the state vector?'. It was that it codifies in a compact way all past information about a system, on the basis of which we can state the probabilistic connections that quantum mechanics gives among a series of measurements carried out subsequently and sequentially in time; all the consequences of quantum mechanics are just such statements. So, as the orthodox view claims, 'the laws of quantum mechanics can be expressed only in terms of probability connections', and cannot be formulated in terms of objective reality.

Pursuing this analysis further, Wigner came to the conclusion that human consciousness is an essential external ingredient needed to make complete sense of quantum mechanics. The collapse of the state vector occurs when and only when an observation is registered in some individual consciousness: 'It is at this point that the consciousness enters the theory unavoidably and unalterably. If one speaks in terms of the wave function, its changes are coupled with the entering of impressions into our consciousness'. And again: '... it was not possible to formulate the laws of quantum mechanics in a fully consistent way without reference to the consciousness'. In support of this declaration, Wigner appeals to Heisenberg and says: 'W. Heisenberg expressed this most poignantly (*Daedalus*, 1958, **87**, 99): "The laws of nature which we formulate mathematically in quantum theory deal no longer with the particles themselves but with our knowledge of the elementary particles ... The conception of objective reality... evaporated into the... mathematics that represents no longer the behaviour of elementary particles but rather our knowledge of this behaviour" '.

As one can imagine, this line of thinking led Wigner inexorably to a kind of solipsism, and to the delineation of two kinds of reality – the content of one's own consciousness, the only absolutely real, and everything else external to oneself, including every other person's consciousness. To support the former he turned to Schrödinger; '... the most eloquent statement of the prime nature of the consciousness with which this writer is familiar and which is of recent date is on page 2 of Schrödinger's *Mind and Matter*: "Would it (the world) otherwise (without consciousness) have remained a play before empty benches, not existing for anybody, thus quite properly not existing?" ' But there was a sign of asymmetry – the only absolutely real, one's own consciousness, does depend on food, air and water for its own survival and functioning, as we are painfully aware; so he made a case for devising experiments which might show up the effects of consciousness on matter. In talking of the first kind of reality, Wigner also realized and stated its obvious limitations – its awakening with birth and infant growth, its extinction at death. So he argued for a deep study of

the former phase, to understand the nature of consciousness.

Wigner felt that the development of quantum mechanics had widened the outlook of most physicists, and also in a sense made them inward-looking: 'Until not many years ago, the "existence" of a mind or soul would have been passionately denied by most physical scientists ... Even today, there are adherents to this view though fewer among the physicists than – ironically enough – among biochemists'. He also saw that quantum mechanics reinforces the circumstance that any observation and interpretation of measurement rests on previously constructed and understood theory. Thus, we are linked in a chain to the very beginnings of our acquisition of knowledge of our surroundings and its regularities – indeed to phylogenesis and ontogenesis.

Today it may seem that these conclusions of Wigner were premature. Certainly, efforts are aplenty to find more 'acceptable' interpretations of quantum mechanics, without appeal to ourselves as essential prerequisites. Was Wigner then 'a victim of his generation'? Should we smile at these conclusions which he found inescapable? Or was he only being ruthlessly honest and expressing clearly what others hesitated to put into words?

Solid-state physics, reactor theory and technology

I will touch upon these areas only briefly. Wigner's interest in problems of solid-state physics and materials science stemmed from a very early date. There must have been links to his original training as a chemical engineer; later on his detailed knowledge of properties of materials played a key role in his work on reactors. Among his gifted students in solid-state science in the 1930s we may mention John Bardeen, Gregory Wannier and Frederick Seitz. It was Wigner who suggested to Wannier[49] 'that there ought to be a way to reconcile the local and the band concept for electrons, and that such a reconciliation would probably be useful in understanding the spectra of insulators'. Wigner also worked on radiation damage in solids – the detailed microscopic picture of lattice defects occurring when materials are irradiated with neutrons, the resulting changes in heat and electrical conductivity and ductility, and also the ways in which the material seems to recover from the damage as time goes on[50].

Wigner was the source of much of the theory and the major technological developments connected with nuclear reactors. His contributions began in 1940. As briefly mentioned earlier, he was a leader at the University of Chicago Metallurgical Laboratory during 1943–45. He contributed to the development of research reactors, power reactors and plutonium production reactors. On the theoretical front he made major contributions to the spectrum of the Boltzmann equation, neutron thermalization, thermal utilization and resonance absorption. All very practical contributions 'which one would hardly, *a priori*, have associated with the same man who introduced group theory into quantum mechanics'[51].

Views on science, philosophy and life

Wigner was a gifted and articulate expositor of science and its principles to general audiences. However, he frequently indulged in a kind of mock humility – as his Princeton colleagues explained his language[52], 'A piece of work is "amusing" if it is correct and beautiful; it is "interesting" if it is wrong and messy.' And in describing the epistemology of quantum mechanics to an audience of nonphysicists, he said of himself the writer[53]: 'He realizes the profundity of his ignorance of the thinking of some of the greatest philosophers and is under no illusion that the views to be presented will be very novel. His hope is that they will appear sensible.' He could convey sharp ideas pithily: 'Some one once said that philosophy is the misuse of a terminology which was invented just for this purpose'.

These apart, his grasp of and concern for the grand principles of science were very deep. The role of invariance principles and their associated conservation laws captivated him – he dwelt upon them at length on many occasions[54], and said: 'A large part of my scientific work has been devoted to the study of symmetry principles in physics ....' He titled his Nobel lecture 'Events, laws of nature, and invariance principles'. He often described as a miracle the fact that human understanding could uncover laws of nature, and separate them from the accidents of initial conditions. The laws provide structure and coherence to events, and, in turn, the symmetry principles provide these qualities to laws; thus one has the ascending progression: events to laws to symmetry principles.

Turning to the role of mathematics in natural science, he expressed wonder at the way in which mathematical concepts and connections show up in unexpected ways and places, and also at the fact that tentative theories turn out upon further development to be far more accurate than could reasonably have been expected at the outset. This led him to conclude that, since we do not quite know why we succeed so well so often, we must be cautious and not immediately regard a successful explanation as the truth!

Pondering on the likely future of science, Wigner wondered whether it might not wind down under its own weight, and lose its attractiveness to the young. The increasing extent of science makes it go beyond the reach of any one individual. But the response to this cannot just be an increase in team efforts, because this can never capture true creative thinking in the individual subconscious. There is a need here to find deeper ways of sharing information and insight, of harmonizing the collective conscious with the subconscious in each individual.

Continuing on the theme of the growth of science and the emergence of large collaborative efforts, he argued for protecting the individual and giving value and esteem to little science: 'One does not have the satisfaction which creative work, as we know it today, provides, if one's activities are too closely directed by others'. About the emergence of deep insights, 'It is hard to imagine how they can be developed other than in comparative solitude'. And as for the pleasures of pursuing science: 'It has been said that the only occupations which bring true joy and satisfaction are those of poets, artists, and scientists, and, of these, the scientists are apparently the happiest.'

Through the description of his work I have tried to convey the fact that Wigner acknowledged very graciously his debt to some of his most gifted contemporaries. He was also generous in his assessment of them. Of von Neumann he wrote: '... whenever I talked with the sharpest intellect whom I have known – with von Neumann – I always had the impression that only he was fully awake, that I was halfway in a dream.' And about Richard Feynman:

'He is a second Dirac, only this time more human'.

Two persons that Wigner had been very close to – Enrico Fermi and von Neumann – both died in their fifties. Wigner described and contrasted their attitudes to the inevitable. With Fermi, 'On a heroic scale was his acceptance of death ... He was so completely composed that it appeared superhuman'. But with von Neumann it was very different: 'It was heartbreaking to watch the frustration of his mind, when all hope was gone, in its struggle with the fate which appeared to him unavoidable but unacceptable'. These experiences must have affected Wigner deeply; at a convocation address to an audience of young students soon after, he said: 'Our culture is committing a sin by covering our eyes against the realization that none of us will be here always'. And to a general audience some time later: 'The recognition that physical objects and spiritual values have a very similar kind of reality has contributed in some measure to my mental peace'. These various expressions seem related.

Wigner was a physicist who achieved rare range and depth in his life and work. He was a product of the old world who flowered during the golden age of theoretical physics, and carried the fragrance of his subject to the new world. The time seems past when such another can appear.

INDIAN INSTITUTE OF SCIENCE
Bangalore 560 012

Postdoctoral Research Associateships in Life Sciences and Biotechnology
(A DBT-sponsored programme)

Applications are invited from candidates with PhD in biological, chemical or physical sciences, or MD, for the award of temporary Research Associateship (maximum duration 2 years) to carry out research in frontier areas of biology in the Division of Biological Sciences at IISc under the DBT-sponsored postdoctoral programme. Candidates who have submitted their theses are also eligible to apply, but they may be appointed as Provisional Research Associates till they obtain the degree. Minimum consolidated emoluments for Research Associates will be around Rs 4,000 p.m.

Candidates should apply on plain paper, giving (1) biodata, (2) a summary of the PhD work, including the list of publications (reprints if any), (3) two reference letters, from the supervisor and from persons familiar with their scientific work, and (4) an undertaking that they will continue with the training programme for its duration.

After initial screening, candidates will be called for an interview at IISc, Bangalore, in the third/fourth week of September 1995. The PDF programme will start from 1 October 1995. Send applications to Prof. K. P. Gopinathan, Convenor, DBT-PDF programme at IISc Chairman, Department of Microbiology and Cell Biology, Indian Institute of Science, Bangalore 560 002, to reach him before **10 September 1995**.

Edited and published by Prof. S. Ramaseshan and Prof. P. Balaram, Current Science Association, Bangalore 560 080.

We'll help you get there

If you're selling science books/journals or laboratory products, or wish to recruit scientists in your establishment, then

you're sure to benefit by advertising here.

Because *Current Science* reaches nearly every university, scientific institution and industrial R&D unit in India. What's more, it's read by hundreds of individual subscribers – students, doctoral scientists and professionals in virtually every field of scientific activity in India.

Current Science has the largest circulation among scientific journals in India.

And to give you more impact, we're now bigger, and better.

Write now, or send your copy to

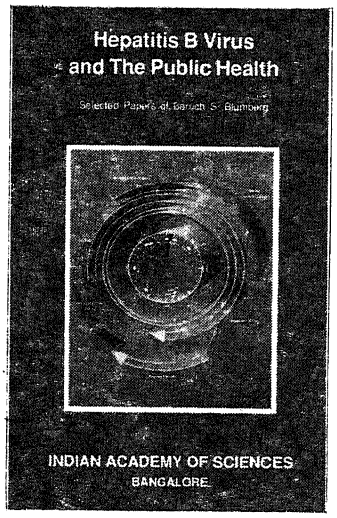
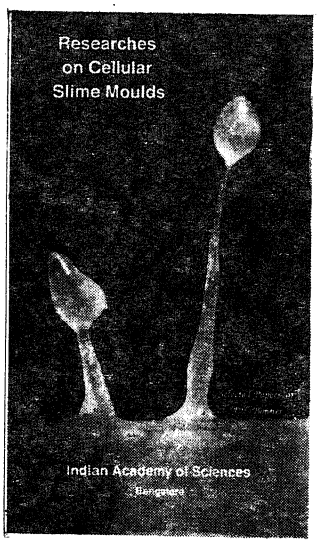
3 SCHOLARLY PUBLICATIONS
from the INDIAN ACADEMY OF SCIENCES





Molecular Conformation and Biological Interactions
G. N. Ramachandran Festschrift

This tribute to G. N. Ramachandran, one of the pioneers in the area of protein structure and conformational analysis, brings together over 40 state-of-the-art articles on protein structure and function, modelling and design of novel proteins, membrane channels, drug design and molecular recognition, nucleic acid structures.

Hepatitis B Virus and the Public Health
Selected papers of Baruch S. Blumberg

Blumberg received the Nobel prize for physiology or medicine in 1976 for his researches on hepatitis B virus and his discoveries of mechanisms relating to the origin and dissemination of infectious diseases. This collection of papers covers a wide range of fascinating topics—virus subtypes, sex ratio, insect vectors, cancer, epidemiology, polymorphisms.

Researches on Cellular Slime Moulds
Selected papers of John Tyler Bonner

Dictyostelium discoideum, the best-studied species of the cellular slime moulds, or social amoebae, is a favourite organism for work dealing with a range of phenomena studied by molecular, cellular and developmental biologists. Perhaps no single person has enriched our understanding of the cellular slime moulds as much as J. T. Bonner.

INFORMATION FOR CONTRIBUTORS

GENERAL

All manuscripts should be addressed to the Editor, *Current Science*, P. B. No. 8001, C. V. Raman Avenue, Bangalore 560 080. Submission of an article will be held to imply that it has not been previously published and is not under consideration for publication elsewhere; and further, that if accepted, it will not be published elsewhere. *Three copies of contributions of all categories* are required, with a letter of transmittal giving (i) names and complete addresses of the authors and (ii) title of the contribution and the category in which it is submitted (see below).

Current Science is a multidisciplinary journal and therefore research and review papers of general significance that are written clearly and well organized will be given preference. All papers will be first assessed by a Reviewing Editor. Papers found unsuitable in terms of the overall requirements of the journal will be returned to the authors. The others will be sent for detailed review. *Both solicited and unsolicited material will be reviewed.* Authors of these papers will be notified of acceptance, rejection, or need for revision of the paper. Returned papers cannot be resubmitted.

Illustrations and other material to be reproduced from other publications must be properly credited; it is the authors' responsibility to obtain permission for reproduction (copies of letters of permission should be sent).

CATEGORIES OF MANUSCRIPT

General articles (not exceeding 5000 words) discuss current trends in research in a field that will be of interest to readers outside the field; interdisciplinary topics: science policy and administration; or some aspect of the application of science and technology to human needs or the impact of science and technology on society/ecosystems/life. They should include a summary not exceeding 100 words, introductory paragraph(s), brief subheads at appropriate places to point to what follows, illustrations that will help a general reader, and references.

Review articles (not exceeding 5000 words) are expected to survey and discuss recent developments in a field. They should be well focused and organized, and avoid a general, 'textbook' style.

Research articles (not exceeding 4000 words) should report research results of fairly major significance. They should include an abstract not exceeding 100 words, introductory paragraph(s), and brief subheads.

Research communications (not exceeding 2000 words) should contain important findings that are novel and of fairly broad interest. They should include a brief abstract and an introductory paragraph. Text should not be broken up under subheads.

Correspondence includes letters, not exceeding 500 words, that are of general interest to scientists. All letters cannot be published.

Scientific correspondence contains technical comments, including those on articles or communications published in *Current Science* within the previous six months. Letters may be reviewed and edited.

Research news articles are intended to inform nonspecialists about recently published advances or important findings discussed at a meeting. Authors should also send a copy of the paper(s) on which the article is based. Meeting reports should avoid merely listing brief accounts of topics discussed, and must convey to readers the significance of an important advance.

Research accounts articles are intended to be personalized reviews of research from the authors' own laboratory, based on a body of published work. The articles must provide appropriate background to the area in a concise introduction, which should also serve to place the author's work in proper perspective. Articles will normally not exceed 8 to 10 printed pages.

Opinion articles present views on issues related to science and scientific activity. **Commentary** articles should contain expository notes on issues related to science and scientific activity.

Book reviews. Unsolicited reviews will also be considered. Reviews that merely 'list' brief descriptions of the contents cannot be published. Reviews should have 'context' and convey some information about the subject of the book.

Historical commentary and notes inform readers about interesting aspects of personalities or institutions of science or about watershed events in the history/development of science; most are expected to relate to India. Illustrations are welcome. Brief items will also be considered.

MANUSCRIPT PREPARATION

Manuscripts should be typed double-spaced on one side of white bond paper (21 × 28 cm). The pages should be numbered consecutively, starting with the title page and through the text, reference list, tables and figure legends. The **title** should be brief, specific and amenable to indexing. Not more than five **keywords** should be indicated separately; these should be chosen carefully and must not be phrases of several words. **Summary** and **abstract** should not have more than 100 words and should convey the main point of the paper, outline the results and conclusions, and explain the significance of the results.

Text. All papers should have a brief introduction. The text should be intelligible to readers in different disciplines and technical terms should be defined. Tables and figures should be referred to in numerical order. All **symbols** and **abbreviations** must be defined, and used only when absolutely necessary. Superscripts and subscripts and ambiguous characters should be clearly indicated. **Units of measure** should be metric or, preferably, SI. Methods should, as far as possible, be described briefly in appropriate table and figure legends.

Figures. In the case of line drawings one set of originals (without any lettering) is sufficient, with two copies containing lettering. In the case of photographs good prints are required with each copy of the manuscript; photocopies are not acceptable. Line drawings should be roughly twice the final printed size. The correct orientation should be indicated if not clear.

Photomicrographs and other photographs that require it must have a scale bar, which should be defined clearly in the legend. Primary data should be submitted as far as possible (e.g. actual photographs of electrophoretic gels rather than idealized diagrams).

References should be numbered in the order in which they appear, first through the text and then through table and figure legends. The following are examples of ways of writing references.

IPS-11

July 28–Aug 02, 1996
Bangalore, India

Eleventh International Conference on Photochemical Conversion and Storage of Solar Energy (IPS-11)

Scientific Programme

The IPS conferences are held every two years with the aim of outlining the latest developments in the field of photochemical conversion and storage of solar energy. The eleventh conference of this kind will cover the following areas:

* Photoinduced electron transfer processes
* Photocatalysis in heterogeneous and homogeneous systems
* Photoelectrochemistry
* Photosynthesis in biological and biomimetic systems
* Quantum chemical studies of molecules on surfaces under the influence of light
* Thermodynamic aspects of quantum solar energy conversion
* Environmental applications of photocatalytic systems
* Materials for photoenergy conversion and photochemical engineering

These topics will be discussed in plenary and at invited lectures, workshops and poster sessions. Contributions from participants are encouraged. A book of abstracts will be distributed at the conference.

Location

The Eleventh International Conference on Photochemical Conversion and Storage of Solar Energy (IPS-11) will be held in the National Science Seminar Complex, Bangalore, India.

International Organizing Committee

E. Amouyal (France): C.A. Bignozzi (Italy): M. Calvin (USA); G. Calzaferri (Switzerland): Y. Cao (China); M. A. Fox (USA); M. Fujihira (Japan); D. Gust (USA); G. Hodes (Israel); V. Krishnan (India); J.-M. Lehn (France); N. S. Lewis (USA); S. E. Lindquist (Sweden); A. Nozik (USA); V. N. Parmon (Russia); E. Pelizzetti (Italy); Sir G. Porter (UK); N. Serpone (Canada); H. Tributsch (Germany); F. Wilkinson (UK); H. Yoneyama (Japan); F. Willig (Germany); K. I. Zamaraev (Russia)

Local Organizers

S. Umapathy and P. K. Das, Department of Inorganic and Physical Chemistry, Indian Institute of Science, Bangalore.

Second Circular

The second circular containing more details will be sent by October 1995. The Organizing Committee would appreciate your supplying this information to others who may be interested in attending the IPS-11.

In this issue

Resurrecting microbiology

Sidney Brenner remarked some time ago that 1990 marked the demise of both biochemistry and communism. For good measure he categorized physiology as an extinct discipline (*Current Biology*, 1995, **5**, 332). Carl Woese recently suggested that 'if microbiology is not dead today, it definitely is moribund' (*Microbiol. Rev.*, 1994, **58**, 1). To the outsider, the present boom in biology would appear to contradict these remarkably harsh assessments on the state of many areas of the science. However, in the headlong rush to clone, sequence and sometimes express genes, most students of biology and bordering areas have gravitated to 'molecular biology'. Armed with a formidable array of cellular and molecular tools, identifying, cutting, pasting and modifying genes appears to be the most desirable activity for new students of molecular biology. Research in this area has advanced at a furious pace with an ever increasing number of companies providing ready-made kits to perform almost any experiment. In universities and institutions where researchers are trained, the unchecked growth of 'molecular biology' has been at the expense of several more traditional disciplines, resulting in a new generation of students unaware of the importance of microbiology, biochemistry and physiology. Are these murmurs of discontent only a case of sour grapes? After all, the molecular genetic approach has provided incisive solutions to many major biological issues and resolved many an impasse faced by the traditionalists. The successes of genome sequencing are already impressive, with the *Haemophilus influenzae* story being the most recent (*Science*, 1995, **269**, 496). Should scientific disciplines be given a graceful burial when their time is past? Or will life in many forgotten areas of biology, if nurtured, result in a new flowering in the future. Ramesh Maheshwari makes a strong and reasoned plea (**page 401**) for vigorously promoting microbiology as central to the study of all biology.

P.B.

Functional imaging

When Paul Lauterbur published the first NMR images of coaxial tubes (*Nature*, 1973, **242**, 190), few would have imagined that the new technique called 'zeugmatography' would herald the birth of magnetic resonance imaging (MRI). The prefix 'nuclear' was quietly dropped when the vast potential of the method in clinical medicine was realized. This undoubtedly enhanced the rate with which this amazing technique entered many areas of diagnostic medicine. MRI has progressed at an impressive pace helped by many fundamental advances in the practice of nuclear magnetic resonance; the introduction of high field superconducting magnets, the development of two-dimensional spectroscopy and the fusion of spectroscopy and imaging. Today MRI facilities exist at many centres in India, with the All India Institute of Medical Sciences (AIIMS) boasting of a Department of Nuclear Magnetic Resonance. The results of the first functional MRI experiments carried out on the 1.5 T whole body scanner at AIIMS are reported by Jagannathan and Raghunathan on **page 448**. The authors demonstrate the possibility of using conventional pulse sequences and equipment for functional imaging. Neuronal activity stimulated by specific physical tasks is shown to affect the magnetic resonance image. The possible applications in neurosciences are many. This will undoubtedly require a very close interaction between neuroscientists and spectroscopists.

SYMPOSIUM
on
U. N. BRAHMACHARI & PERSPECTIVE OF KALA-AZAR RESEARCH

Indian Institute of Chemical Biology
Calcutta 700 032

Date: 3–4 November 1995

TOPICS OF SCIENTIFIC SESSIONS

1. History of Kala-azar research and contributions of Professor Brahmachari
2. Clinical profile of the disease including PKDL
3. Epidemiology and transmission dynamics of the disease
4. Chemotherapeutic approach
5. Vector biology and control
6. Immunobiology of host–parasite interaction
7. Biochemistry and molecular biology of Leishmanial parasites
8. Pathophysiology of Leishmaniasis
9. Diagnosis
10. Control

CURRENT SCIENCE

Volume 69 Number 5 10 September 1995

NEWS

Peer review under scrutiny

The practice of seeking an expert's comments on submitted articles is as old as *Philosophical Transactions of the Royal Society* and is the central mechanism for assessment of the quality of manuscripts before publication in scientific journals. In recent years, a number of editorials and articles have addressed various issues related to the process of peer reviewing, reflecting the increasing interest on the subject[1-7]. Six years ago, thanks to the efforts of the editors of some of the leading medical journals, a conference on peer review was held in Chicago, Illinois[8]. The meeting focused attention on problems connected with manuscript assessment and helped to stimulate research into relevant aspects of peer review.

A second international congress on peer review in biomedical publications was held in Chicago, Illinois, in September 1993 and brought together editors and researchers from 20 different countries. *The Journal of the American Medical Association* (JAMA) has devoted one of its recent issues to publishing 26 articles selected from 110 papers presented during the conference[9].

The published papers discuss several interesting aspects such as effectiveness of peer review as a quality control mechanism, role of blinded reviews, author's views on editorial practices and cognitive aspects of manuscript assessment.

M. Abbey, M. D. Massey, S. Galandiuk and H. C. Polk (*The American Journal of Surgery*) determined what percentage of manuscripts rejected by their journal were subsequently published in other journals indexed by MEDLINE. They found that 62% of the manuscripts rejected by them remained unpublished in core medical journals. More than half of the articles, ultimately published, appeared in journals with a lower circulation rate. Their findings imply that review process effectively prevents publication of manuscripts of a lower quality.

The effect of peer review and editorial processes on the readability of articles has been measured by J. C. Roberts, R. H. Fletcher and S. W. Fletcher (*Annals of Internal Medicine*). Editorial practices were found to improve the readability of the articles as measured by indices such as the Gunning fog index and the Flesch reading ease score. Readers, mostly practising physicians, however did not agree with the peer assessment with respect to the importance of published articles. Articles which received high marks for importance were often judged as less relevant to clinical practice. This difference in opinion may be because the reviewers recommend articles containing new information and the clinicians are reluctant to accept unestablished findings.

Peer review is thought to be a good defence against scientific misconduct. Yet, numerous articles with fabricated or plagiarized or redundant (duplicate) data get published despite peer review. H. N. Nigg and G. Redulescu (*Bulletin of Environmental Contamination and Toxicology*) report four cases of misconduct encountered in their journal since 1990. In three cases, the authors belonged to institutions in India.

P. A. Rochar *et al.* of Mount Sinai Hospital confirm our suspicion that scientific articles published in journal supplements are generally of inferior quality when compared with those published in the parent journal. Their finding is based on assessment by blinded reviewers of the quality of articles on randomized control trials of drug therapies published in *American Journal of Cardiology*, *American Journal of Medicine* and *American Heart Journal.*

What is the impact of blinded peer review? D. N. Laband and M. J. Piette from the Department of Economics, Auburn University, drew a sample of 1051 articles in 28 economics journals published during 1984 and found that articles in journals using nonblinded peer review received lesser number of citations than those in journals using blinded peer review. Journals using nonblinded review appear to publish a large number of papers that should not have been published.

The basis for recommending blinded reviews is that many researchers have the apprehension that reviewers recommend and editors accept articles that originate from prestigious or better-known institutions and those submitted by authors who have more previous publications. J. M. Garfunkel and colleagues (*Journal of Paediatrics*) found in their analysis that there is no difference in the acceptance rate of major manuscripts from institutions of greater prestige and from other institutions. However, a significant correlation existed between institutional rank and recommendations or decisions to accept case reports and brief reports. M. Fisher, S. B. Friedman and B. Strauss (*Journal of Developmental and Behavioural Paediatrics*) also concluded from a randomized controlled trial that there was no significant difference in the scoring of manuscripts and recommendations when reviewers were either blinded or nonblinded to the previous publication record of the author.

Another form of bias suspected in handling of manuscripts is gender bias. J. R. Gilbert, E. S. Williams and D. G. Lundberg (JAMA) assessed whether the manuscripts received by the journal had different manuscript processing characteristics associated with the gender of the corresponding author, editor and reviewer. Participants in this retrospective cohort

study included 8 male and 5 female editors, 2452 male and 930 female reviewers and 1698 male and 462 female authors. Interestingly, the study revealed that gender differences exist in editor and reviewer characteristics. Female editors summarily rejected manuscripts at a higher rate than male editors ($p < 0.001$!). Male editors utilized male reviewers more often than female reviewers, while female editors used reviewers of both genders at equal rates. Female editors were assigned manuscripts with female corresponding authors at a higher rate. Male reviewers took significantly longer time to return the manuscripts than female reviewers. Gender of the reviewers and corresponding authors had no association with the recommendation made by the reviewers. There was no evidence of gender bias in the final acceptance rate of manuscripts.

M. Nylenna, P. Riis and Y. Karlsson (*Journal of Norwegian Medical Association*) studied the association between the characteristics of referees and their assessment of manuscripts, and also the influence of manuscript language. Experienced and young referees were found to provide better reviews than their older colleagues. In Scandinavian countries, an English version of a manuscript was more easily accepted than its national version, and the submission of an article in mother tongue appeared to be a handicap.

How do authors view editorial practices? The subject has been investigated by B. J. Sweitzer and D. J. Cullen (*Journal of Clinical Anaesthesia*). They ascertained from authors of unsolicited articles their views on the evaluation of their manuscripts. Opinion was sought on timeliness, quality, clarity, specificity and educational value of reviewer's comments as well as their satisfaction or dissatisfaction (because of delay, unclear comments, overlooking important data, tone of the review, lack of knowledge of the reviewer, etc.) with the reviews. Authors of accepted manuscripts gave a favourable rating for reviewers. Authors of articles in the category of 'accept with revision' were satisfied that the review process led to improvement in their manuscripts. Authors of articles in 'reject but resubmit' category believed that the review process improved subsequent preparation of manuscripts. Worst scores were provided by authors of 'reject outright' articles. Only 30% in this group responded and among them only 20% believed that they were helped by the review process.

Can the nature of manuscript assessment be improved to help editors in decision making? Editors often encounter situations when reviewers do not agree in their recommendations on a manuscript. On such occasions editors either use an arbitrary cut-off score to determine acceptance or use their discretion. Editors would be helped if the reviewers provide a structured assessment and there are objective criteria to measure the reliability and quality of reviews.

J. P. Kassirer and E. W. Campion (*New England Journal of Medicine*) in their paper discuss the cognitive aspects of manuscript assessment. They try to blunt the criticism that there are no rules governing peer review and that the process is arbitrary and subjective. They point out that the fundamental task of a manuscript reviewer is to 'detect and describe flaws' and that in the assessment of manuscripts there is a rejection threshold – a level at which the cumulative faults of a paper turn the scales towards rejection. Manuscript assessment also has a sensitivity and specificity. Wrong recommendations are unavoidable in the review process since even in the best of hands false positive and false negative results do occur. If this state has to change, the cognitive aspects of how a reviewer makes an assessment of manuscripts have to be better understood. J. P. Kassirer and E. W. Campion (*New England Journal of Medicine*) have categorized and listed the various aspects of a manuscript on which a reviewer is expected to comment. The categories include deficiencies of design, deficiencies in presentation, deficiencies in interpretation and assessment about the importance of research. Under each category flaws are listed. The list makes the reviewers' job in making objective assessment on articles easy.

M. K. Cho and L. A. Bero from the Institute for Health Policy Studies, California, have developed two instruments, one for measuring the methodologic quality and another to assess the clinical relevance of reports on clinical research. Both have been tested and found reliable, valid and applicable to a variety of research designs.

A grading instrument with a 14-point scoring system and a scoring guide to measure objectively the quality of reviews is provided by I. D. Feurer *et al.* (*Journal of Vascular Interventional Radiology*). The seven attributes in the system include timeliness, etiquette, completion of a grade sheet, and provision of (i) sectional reviews, (ii) supporting references, (iii) specific recommendations and (iv) new insights or perspectives. The authors have tested the scoring system and found it valuable to identify outstanding and weak reviewers.

Authors' misconduct receives considerable publicity while editorial misdeeds are unpublished. Dishonesty, favouritism, victimization and nondeclaration of conflict of interest are recognized as some of the unethical editorial practices. The true prevalence of editorial misdemeanour is unknown. D. G. Altman, I. Chalmers and A. Herxheimer from Oxford, England, draw attention to three cases of editorial misdeeds. One case is that the editor republished an article which appeared in another journal without consulting the author and then attacked it in an editorial, refusing a chance for the author to reply. Another case involved plagiarism of a commissioned review article. The third is an instance of not disclosing the editor's vested interest, which led to unfair assessment of a manuscript describing a randomized controlled drug trial. Altman and colleagues suggest that an International Medical Scientific Press Council be established to set a code of conduct for editors and to investigate when there is breach of prescribed conduct.

Journal publishers are concerned with the way in which authors select the journals for submission of their articles. Eric Frank from Emory University School of Medicine conducted a survey among the clinical and research faculty of Stanford University School of Medicine to evaluate authors' criteria. The most important factors for initial manuscript submission were journal prestige, the frequency with which a journal publishes related articles and the composition of the readership. Likelihood of acceptance, turn-around time, prior publication in a journal and acquaintance with the editor gained importance for subsequent submissions.

H. F. Judson of Stanford University draws attention to factors that threaten the peer review process. He writes: 'What was a high and interesting duty has become a wearisome chore'. Waning dedication and enthusiasm of the participants in the peer review process are likely to

lead to declining standards. He also cautions that peer review, which began as a measure to shield the autonomy of science from administrators and politicians, is threatened by internal politics such as rivalries between scientists and the likelihood of theft of ideas and insights by peer reviewers, who are often competitors of the authors of articles. Judson predicts that structural transformation in sciences would have its impact on peer review processes. Shortage of funds for research, intensification of competition, increasing pressure from funding agencies for research targeted at national needs, with emphasis on industrial and technological exploitation of research, are characteristics of the current transition. Profit motives determine the direction of research. Criteria for the evaluation of a research work are determined by non-scientists and the emphasis is on outcome and endpoints than on inputs. Yet another transformation is the development of electronic collaboration, which offers considerable options for interaction between editors, authors and readers. New procedures for manuscript assessment are expected to replace the current practices.

What did the participants feel after the congress? Attitude survey conducted after the conference revealed that a vast majority of respondents thought that peer review improves the quality of publication, that the journals should adopt uniform standards for peer review and that the editors should encourage research to establish baseline data on the prevalence of scientific fraud. Among the respondents, 95% said that conferences on editorial peer review should be held regularly in the future.

CORRESPONDENCE

What NSU report leaves unanswered!

This refers to the Special Section of *Current Science* (25 June) in which you have closed the debate on NSU. To me it appears that the debate has been ineffective and inconclusive. I was surprised and somewhat disappointed to note that you have not summarized in clear terms, with reasonable details, what your authors and readers have generally opined about the new university. In your 'In this issue' column, there appears a remark: 'there were few supporters of the NSU concept'. I just wonder if the term *few* is actually intended to mean *some* (equivalent to *a few*) or to imply *hardly any* (which it really does)! In the latter case, your authors' and readers' message is rather clear.

There are a few important questions that have been left unaddressed in the final report. Supporters of NSU and those actively engaged in its establishment should feel obliged to give serious thought to these. Some of them are:

1. NSU will be producing some 200 Ph D's every year. Where would they be expected to go? Would they accept to work in other Indian universities/colleges whose academic environment would hardly match that of the said university?

2. Will the phenomenon of brain-drain not apply to the trained scientists coming out of NSU? Will they be allowed to go abroad, since in a free and democratic country nobody can be stopped from searching for a better working place? Will we allow brain-drain, giving the argument that science is universal and that complete mobility must be granted to scientists so that they could work in a place of their liking? But then we have to remember that there are moments when we become specially conscious of our nationalism and start talking of things like Indian science.

3. The report states that NSU would also train foreign students. Why spend the available resources on foreign students? Why not train more and more Indian students? After all, the university would hardly be able to cater to the academic needs of our vast population. That means we would be obliged to concentrate our efforts fully on training as many Indians as possible.

I have a suggestion to make. All those who are involved in erecting NSU – a temple of academic excellence – should avoid accepting a faculty chair or any other position of importance on the completion of the task. In the end, they should hand over the institution to deserving people from within the country and from outside. This will reinforce the faith reposed on them by the general public and will also succeed in impressing upon the skeptics that NSU was not being created in their own interests but in the interest of the nation. Let us remember that great men, whose actions are motivated by a deep-rooted concern about the welfare of the society, gracefully leave a completed project to others to look after and move on to a newer venture.

Proposal for a National Science School

Many responses to the proposal for a National Science University (NSU) and the report on 'University Education in Science' clearly show that this kind of a discussion was long overdue.

The objective of setting up the first three universities of the country – Bombay, Calcutta and Madras – in the middle of the nineteenth century was to train personnel to work for the administration, under British superiors. The Indian officers were expected only to obey orders. Because of this there was no emphasis on independent thinking or innovations in these universities. It was feared that these would lead to indiscipline. A university degree was (still is?) considered as a passport to a good job, to earn a decent living. In a job, one was expected only to respect the superiors, obey orders, perform duties and follow rules. At the time of independence there were nearly 20 universities, and now there are around 200. In spite of this phenomenal increase in the number, the university system still remains as a hangover of the colonial past. Only as recently as 1993–1994, introduction of 'vocational' components at the undergraduate level is realized as necessary. Science education in India suffers the most because of the lethargy to modify the system according to the changing times. There is an urgent need to reform science education radically at the school, college and university levels.

Increased political interferences in the functioning of the universities and the trend of appointing Vice-Chancellors on political considerations are the major reasons for their rapid deterioration. In initial appointments and in promotions, when 'ministerial approbations' can substitute for many years of hard work (in libraries and laboratories), how can meritorious and dedicated research workers enter our universities as faculty members and how can the existing faculty members sustain their interest in research. Something needs to be done (very urgently) to keep (politics and) politicians away from our universities.

The problems of research institutions are many. Most important among them are: (i) a career in science remaining the last resort for those who opted for the science stream and failed to make it to a professional course, (ii) confusion whether science is a 'profession' or a mere job and (iii) poor career prospects.

In all work environments there are three categories of people. The first category enjoys the job, gets involved in it completely and does not need any external motivation. These people are sincere and have a natural liking for their jobs. For them, job is like a favourite hobby and a mission. The second category considers the job only as a means to earn money; their involvement in the job is very little, and their enjoyment is elsewhere. They put in the least possible efforts necessary to continue in their jobs. The third category is interested in everything else except work. They are interested in money, promotions, authority, manipulating and controlling people, publicity, etc. These are the politicians of the workplace. They do not promote any cause other than their own career, for which they may be willing to do anything and everything. Our science establishments are also filled with these three categories. And the tragedy is that people belonging to the first category are very few.

To have more people belonging to the first category in our science establishments, we must start searching for students having a natural liking for science. This needs to be done at a very early stage. First, many regional science schools (RSS) need to be established (these schools can be similar to Sainik schools). This should be followed by a National Science School (NSS – similar to the National School of Sports). Admissions to RSS and NSS can be on the basis of a national talent search examination, at the end of lower primary school (LPS) and upper primary school (UPS) stages, respectively. The syllabus and teaching in the RSS and NSS must have greater emphasis on science. Once these students complete their studies in the NSS, they can be trained in a National Science Academy (NSA). The NSA can be similar to the National Defence Academy (NDA). After completing studies/training in the NSA, they can go to a National Science University (NSU). Starting an NSU without doing this ground work is very unlikely to bring about the desired changes.

Another ill plaguing our science establishments is the absence of any distinction between scientists and technicians. Research institutions are like any other government offices. Much in the same way as lower division clerks (LDCs) get promoted to Class I officers in the course of time, technicians also become scientists on the basis of seniority. This raises a basic question – Who is a scientist? Can anyone become a scientist? In defence services there are officers and other ranks. In medical profession there are doctors, nurses and pharmacists. In all these, the selection procedures are different, and the duties, responsibilities and pays are also different. The promotional avenues of other ranks are different from those of officers. Nurses and pharmacists do not become doctors on the basis of seniority. Why is there no such distinction in science? Excepting ICAR, where there is an ASRB (Agricultural Scientists Recruitment Board), why is there no Scientists' Recruitment Board?

Lastly, will this NSU become a 'super IIT', from where scores of young Ph D's and faculty members would migrate to greener pastures? In that case, what purpose will it serve the country? We must stop producing professionally qualified manpower for other countries. There has to be at least a rough estimate on our need for trained/skilled manpower in different areas, and only somewhere near that many people should be trained. The service conditions of scientists need to be made attractive so that best students opt for science education and a career in science.

The ultimate constituents of matter

For over 25 centuries, human curiosity about the ultimate constituents of matter in the universe has remained without a satisfactory solution. Ancient scientists recognized five fundamental elements, viz. earth, water, fire, air and ether. Yet, most philosophers believed that there must be a single kind of homogeneous material that constitutes the universe. Much of the philosophical thinking is guided by this axiom. On this point the schism of intellectuals into the 'two cultures' is not of recent origin. With the progress of science, the count of chemical elements grew from five to over a hundred. Subatomic particles too are not of one kind. However, philosophers as well as some scientists expect to find homogeneity and uniformity in matter in its minutest form. This belief seems to be the main prop for the 'modern scientific' interpretation of the philosophy of the *Upanishads*. As K. V. L. Sarma has reviewed admirably (*Curr. Sci.*, 1995, **68**, 605) the current state of knowledge, we now have a standard model (SM) of six quarks and six leptons, besides the gauge bosons, the transmitters of force.

Although Sarma does not discuss any 'philosophical' implications of the SM, any reader of the review will wonder if in ultimate analysis we might reach a paradigm of uniformity and homogeneity. Shall we conclude that philosophers' paradigm is only an idol of the tribe (*idola tribus*), to use Francis Bacon's terminology? In other words, can we conclude that uniformity of matter in its minutest form or in its primeval state at the Big Bang is a theoretical impossibility? If so, what could probably have guided ancient philosophers to their belief on the nature of matter?

K. VASUDEVA RAO

K. V. L. Sarma replies:

With regard to the comment of K. Vasudeva Rao, the speculation that there is some homogeneous stuff underlying the physical universe is perhaps quite natural and is indeed at the heart of the reductionist approach. History has repeatedly shown that things become simple when we go to the next substratum – molecules, atoms, nuclei, nucleons,... Maybe this is the only monotonous way Nature works, as we go on unravelling the successive onion layers.

There have been many attempts to construct composite models viewing the quarks and leptons, as well as the gauge bosons, as composites of the same fundamental objects, variously called as 'preons', 'rishons', 'subquarks'.... These models are unsatisfactory because proliferation is still present in them although at a different level (postulating many kinds of preons and hyper colour forces to bind them), and they do not lend themselves to any meaningful experimental tests. However, as of now, there is no experimental evidence to suggest that quarks or leptons have any structure, leave alone a common one.

Record of Upper Gondwana flora from Bairam–Belkher area of district Amravati, Maharashtra and district Betul, Madhya Pradesh

This note records the plant fossils from Gondwana succession of Bairam (21°22′–77°37′)–Belkher (21°22′–77°31′) area, falling partly in Amravati district of Maharashtra and partly in Betul district of Madhya Pradesh. The fossils are represented by *Ptilophyllum*, *Sphenopteris*, *Cladophlebis*, *Taeniopteris*, *Matonidium*, *Pagiophyllum*, *Elatocladus* and *Araucarites*.

In regional set-up the area is represented by the Archaean Gneisses, Gondwanas, Lametas and Deccan Trap[1,2] (Figure 1, Table 1); however, the Archaean Gneisses is not exposed in the area. The Gondwana rocks are exposed in the form of isolated patches in the widespread Deccan Trap. It is about 100 m sequence represented by clastic sediments of arenaceous and argillaceous nature, having variable thicknesses (Figure 2). Pinching of the strata is frequently noticed in the beds of sandstones and clays in the upper part of the sequence. Clay is noticed to be of variable colours, viz. grey, dark grey, red, violet and brown to yellowish brown. Incidentally, grey to dark grey clays have been found productive for megafossil remains.

The age of the sequence is still a matter of debate. On the basis of lithological similarities, stratigraphic position, absence of fossils, it was earlier considered equivalent to Kamthi and (?) Mahadeva[1,3]. In the same way, Pachmari and Malari of Upper Triassic have also been correlated[4]. However, the age and correlation proposed, so far, were very casual and no macropalaeontological criteria have been taken into consideration. In recent years, the sequence has been ranked Neocomian–Aptian[5] on the basis of palynology.

The present assemblage is dominated by species of *Ptilophyllum* though *Taeniopteris* and *Matonidium* are very common, followed by *Sphenopteris* and *Cladophlebis* (Figure 3). The rest are poorly recorded. The recorded assemblage is comparable with Early Cretaceous assemblage of the Upper Gondwana

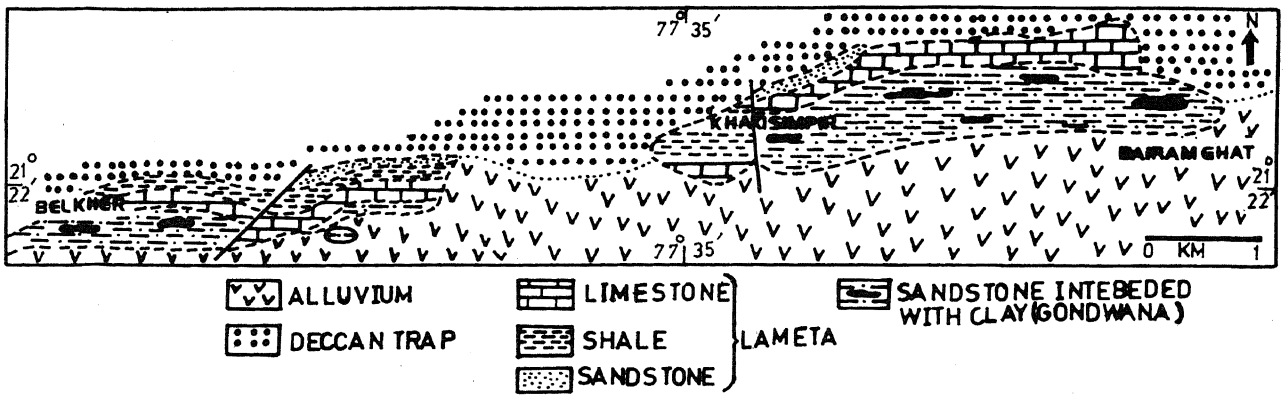

Figure 1. Geological map of the area (after ref. 2).

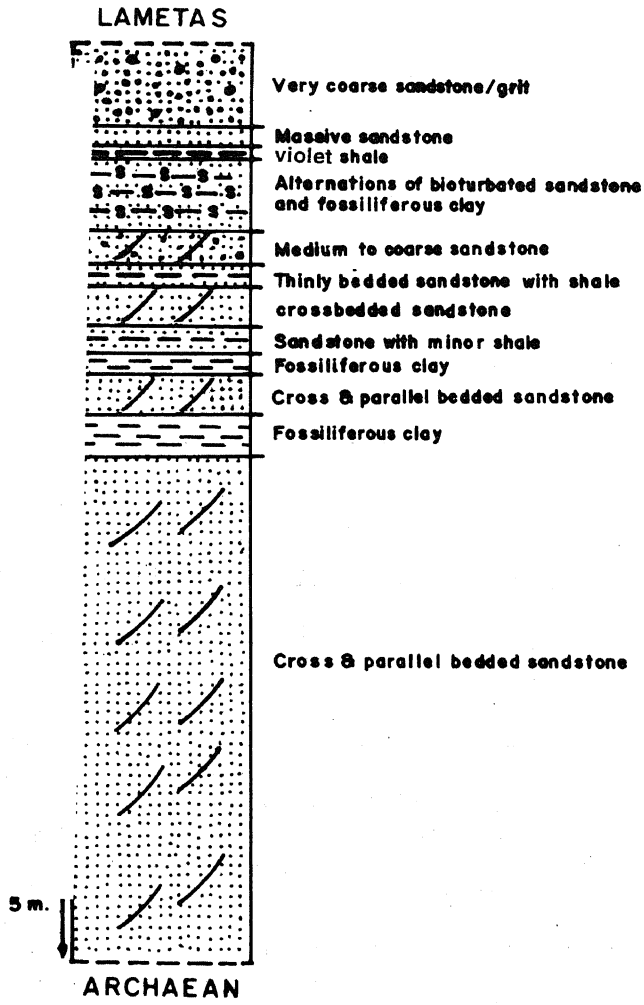

Figure 2. Lithological succession of the Gondwana sediments.

Formations of peninsular India (Table 2). However, the dominance of *Ptilophyllum* and *Taeniopteris* makes it more closer to Dubrajpur, Gollapalli and Jabalpur flora, which are Late Jurassic to Early Cretaceous in age[1,8–12]. The frequent occurrence of *Matonidium* is also comparable with Early Cretaceous of Himmatnagar[11,13]. The palynological evidences are also suppor-

Table 1. Generalized stratigraphy of the area

Age	Formation/Group	Lithology
Quaternary		Soil and alluvium
	Unconformity	
Miocene to Late Cretaceous	Deccan Trap	Nonporphyritic to porphyritic basalt
	Unconformity	
Late Cretaceous	Lametas	Shale, limestone and sandstone
	Disconformity	
Early Cretaceous	Upper Gondwana	Clay, shale, sandstone and conglomerate
	Unconformity	
Archaean		Quartzofeldspathic gneiss

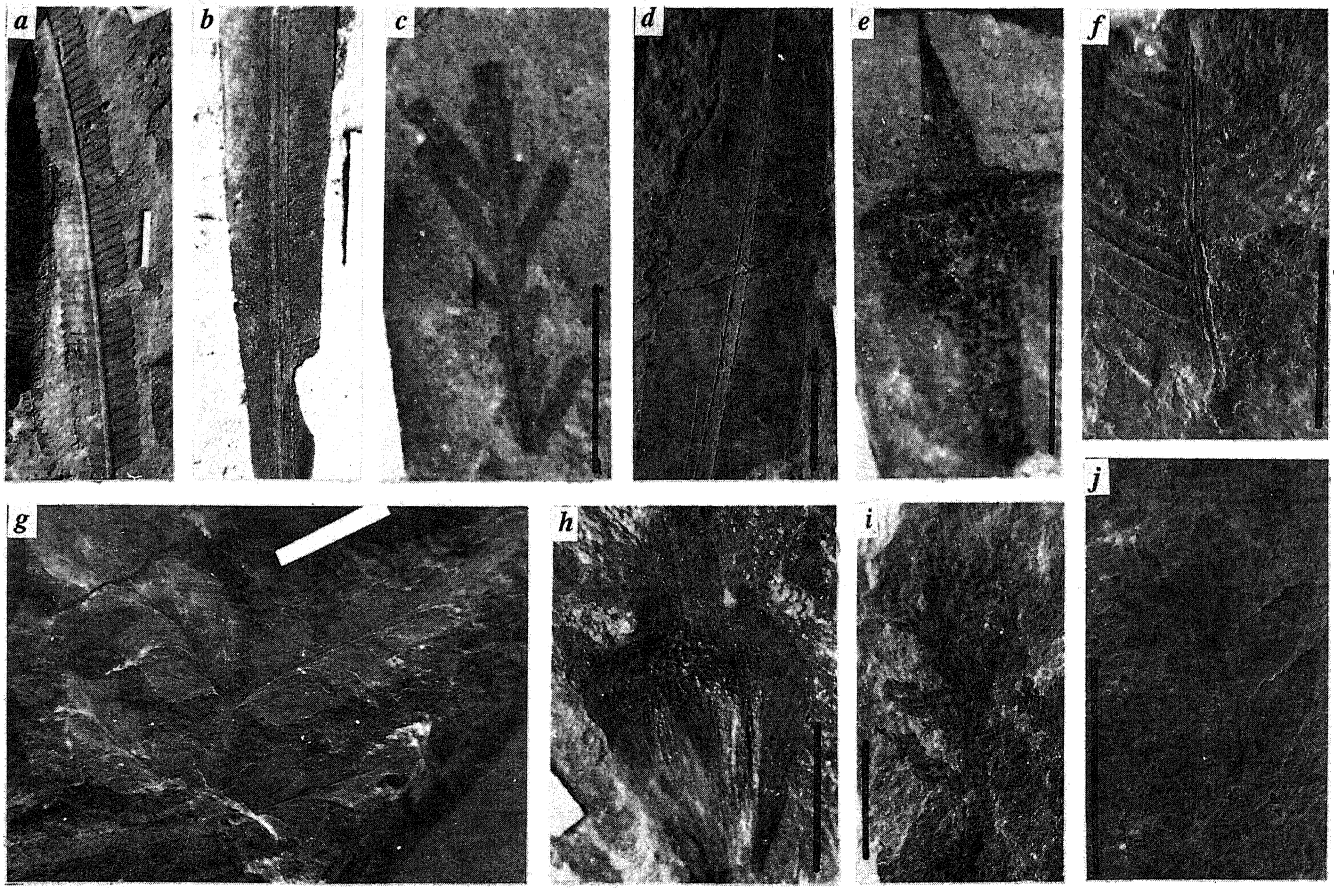

Figure 3. Photographs showing: *a*, *Ptilophyllum*; *b*, *Taeniopteris*; *c*, *Elatocladus*; *d*, *Taeniopteris*; *e*, *Araucarites scale*; *f*, *Matonidium*; *g*, *Sphenopteris*; *h*, *Araucarites*; *i*, *Pagiophyllum*; *j*, *Cladophlebis* (scale: 1 cm).

tive of Early Cretaceous age of the sequence[5]. Hence, the age and correlation proposed so far by the earlier workers is rejected and Early Cretaceous age is assigned.

The climate was warm and humid, as represented by luxuriant growth of Bennettitales and Cycadales[14]. This is also supported by pollen and spores reported from the area[5]. The dominance of cycadophytes over the conifers is also suggestive of tropical to subtropical climate as proposed for Early Cretaceous megafossil assemblage of Dubrajpur[8].

The samples are preserved in the P.G.

Table 2. Comparison of the Amravati plant fossil assemblage with that of other localities known from peninsular India

Genus/Locality	Present locality	Gardeshwar[6] (Early Cret.)	Gangapur[7] (Early Cret.)	Dubrajpur[8] (Late Jura. to Early Cret.)	Gollapalli[9] (Early Cret.)	Jabalpur[1,10,12] (Late Jura. to Early Cret.)	Umia[1,10,12] (Early Cret.)

First report of the Late Permian sporangiate fructification *Nesowalesia* Pant from India

Nesowalesia edwardsii, a Late Permian, sporangiate, monotypic fructification, is instituted by Pant[1] for concave disc-like organs from Newcastle, New South Wales, Australia. *Arberiella* type of sporangia are found attached on the concave side of the disc, while the convex side is smooth. Later on Rigby and Chandra[2] presented additional information concerning *Nesowalesia edwardsii* Pant on the basis of carbonized specimens found from the Late Permian Illawara Coal Measures of the Western Sydney Basin, New South Wales. They also found well-preserved taeniate bisaccate pollen *Striatopodocarpites solitus* (Bharadwaj and Saluja) Foster[3] from the *Arberiella* type of sporangia obtained from a thick crust of carbonaceous concave discs of *Nesowalesia edwardsii*. Rigby and Chandra[2] also proposed a peltate disc type of restoration for this Australian male fructification.

Two such discs having *Arberiella* type of sporangia are recorded for the first time from Late Permian bed exposed in Hinjrida Ghati near Handapa village, district Angul, Orissa. The concave discs are 1.5 cm in diameter and bear a number of *Arberiella* type of sporangia. Since the specimens are in the form of impressions, further studies are not possible. A close comparison between Indian and Australian specimens is also not possible as the

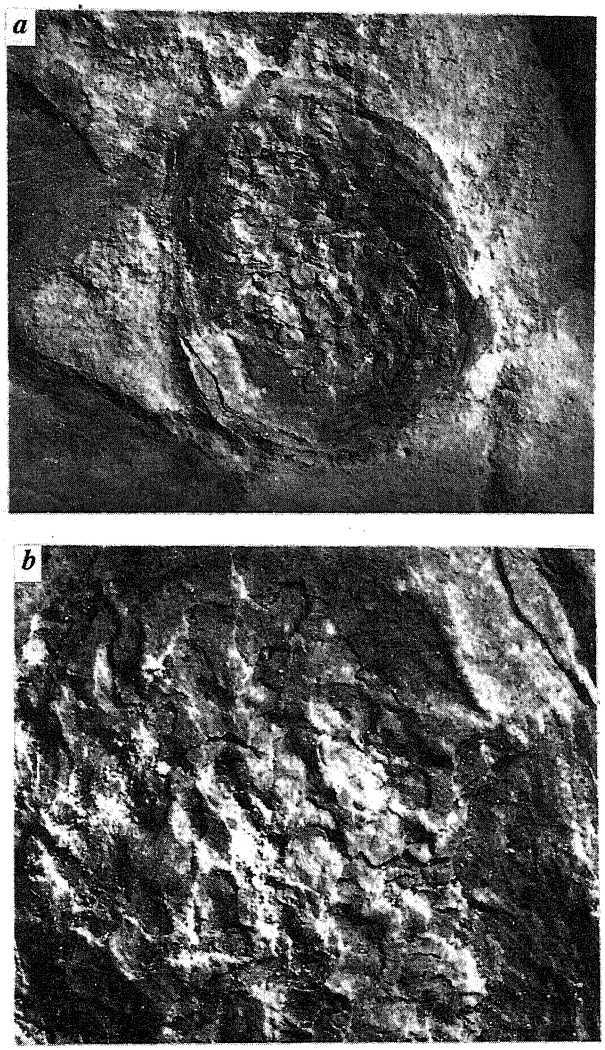

Figure 1. *a*, *Nesowalesia pantii* sp. nov. Specimen showing a concave disc with sporangia. Holotype specimen no. 36869 (×3); *b*, Enlargement of a portion of specimen in *a* showing numerous sporangia (×8).

mode of preservation in the two is different, the Indian ones being impressions while the Australian ones are carbonized. Indian specimens from Handapa are designated as a new species *Nesowalesia pantii* (holotype specimen number 36869, Birbal Sahni Institute of Palaeobotany, Lucknow) with a diagnosis 'concave disc-shaped organs with *Arberiella* type of sporangia' (Figure 1). The Indian specimens closely resemble the specimen described by Pant[4], photographed as Figure 7 on Plate 21.

Report of *Nesowalesia pantii* from Handapa bed is very significant as it is the first report of this sporangiate fructification from India.

COMMENTARY

Whither microbiology?

Ramesh Maheshwari

A distinguished American microbiologist, C. R. Woese, has expressed deep concern at the present state of microbiology. He is of the opinion that all biology should be reorganized around microbiology. The merit of this view is examined. Some examples are given to illustrate the contributions of microorganisms to the understanding of biological principles and formulation of concepts. A possible area of microbiological research is identified which could become the focus of activity involving many young scientists in our country and contribute to the vitalization of microbiology.

In a recent commentary on the state of microbiology, Carl Woese expressed concern thus[1]: 'University microbiology departments are withering. We are eliminating them as entities in their own right, being demoted to ineffectual

"programs" within departments whose names typically begin with "molecular" or "cellular".... In those that remain as microbiology departments in name, the emphasis in both teaching and research is shifting away from microbiology *per se*....' Increasingly, microbiology in these departments is becoming confined to that of growing of microorganisms for 'cloning, sequencing and expressing genes'. Elsewhere[2], Woese says: 'Microbiology is inadequately represented in the funding agencies. Students (and professors) genuinely interested in microbiology are increasingly hard to find. Microbiologists are afraid to teach real microbiology any more.... If microbiology isn't dead today, it definitely is moribund.' One may dismiss these criticisms as prompted from some occupational frustrations, such as the lack of sufficient funds for work, or lack of success in scientific research or the desire to attract attention. I am certain that none of these apply in the case of Woese.

Many biologists would recall that in the last decade somebody had pulled off a coup in biology. We had learned that all living organisms can be classified into two superkingdoms based on fundamental differences in cellular features: the prokaryotes (cells without a nucleus) and the eukaryotes (cells with a true nucleus). The tree of life had two main stems – one stem prokaryotic comprising the bacteria, and the other eukaryotic comprising plants and animals, the latter derived from the former. Woese's studies brought a fundamental revision of this picture. Examining the relationship between prokaryotic microorganisms by comparing the sequences of ribosomal RNA, Woese made the surprising discovery that the world of prokaryotes comprises unusual microorganisms, very different from the typical bacteria found in soil and water. (Imagine Woese's disbelief when, for example, a methane-producing microorganism which had all along been considered a bacterium turned out to be not a bacterium at all!) These microorganisms, which Woese named the archaebacteria (now called the Archaea), are found in unusual places such as hot springs, rumen of cattle, salt pans and brines. They not only differ from most bacteria in sequence of ribosomal RNA but also in biochemical features, such as the absence of muramic acid in cell wall and the presence of ether-linked membrane lipids. The archaebacteria are closer to eukaryotes than to typical bacteria. Their discovery showed that life on earth consists of not two but three primary domains: the Bacteria, the Archaea and the Eucarya. The new tree of life (Figure 1) is a framework for analysing the evolution of all life on earth. Woese placed the study of microbes in an ecological and evolutionary context. In recognition of his contributions, a hyperthermophilic archaeon, *Pyrococcus woesei*, which can grow at near 100°C, was named after him.

The concern expressed by this dedicated and distinguished microbiologist merits serious consideration. Woese contends that all of biology should be reorganized around microbiology. Surely, nobody will deny that microorganisms are important. Microbes cause diseases, make soil fertile, they allow cattle to digest grass, they clean up the environment, and they are used in the manufacture of antibiotics and alcohol. Beer and wine making, which involves alcohol fermentation by the yeasts, are very profitable industries! But, is the general, medical or industrial importance of microorganisms the compelling reason for biology to be reorganized around microbiology? Is the study of microorganisms crucial for learning and formulating biological mechanisms? Although I have no pretensions of being a real microbiologist, I believe that this narrative would demonstrate, at least approximately, the importance of microbiology in *all* biology. The report identifies a possible area of activity which could involve many microbiologists in our country and contribute to the vitalization of microbiology.

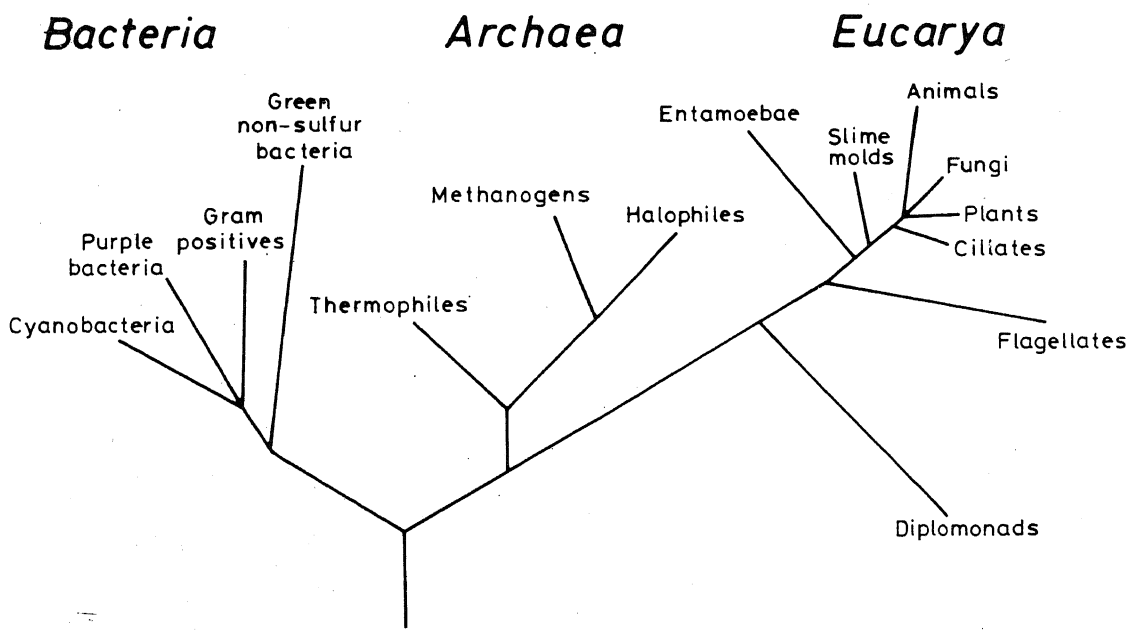

Figure 1. Universal phylogenetic tree determined from ribosomal RNA sequence comparisons showing the three domains, Archaea, Bacteria and Eucarya (based on ref. 2).

Teaching of microbiology

Microbial growth. We begin by the gesture of putting a few cells of a bacterium or yeast in a nutrient medium and measure cell numbers at regular intervals. Let us plot the logarithms of the numbers of cells as ordinate against time. The population displays a characteristic pattern of increase, the S-shaped sigmoid curve. We observe that after a short lag, the amount of living matter increases not in direct proportion to time, but according to geometric progression with time (exponential growth). In other words, the living matter multiplies itself by a constant factor in each successive unit of time. We learn that life is an autocatalytic process. However, the growth which started unrestrictedly stops abruptly when the population runs out of resources[3]. In this planet with dwindling supply of resources, the microbial growth curve has an obvious message for the humans.

Enrichment culture. Next, we prepare a synthetic medium containing a carbon source and mineral salts but lacking in nitrogen. We inoculate this medium with a pinch of garden soil and incubate it at room temperature. We note that microbes with specific metabolic properties develop in this medium. In this particular case, the medium selectively allows growth (enrichment culture) of microorganisms that can fix atmospheric nitrogen to the exclusion of numerous other microbial types present in the soil[3]. This simple exercise strikingly demonstrates the principle of natural selection in just a matter of few hours!

Microbial metabolism. We turn our attention to microbial metabolism and get acquainted with the sequence of reaction steps beginning from glucose and leading to the formation of ethyl alcohol, lactic acid, acetic acid or glycerol, depending upon the microbial species[3]. It suffices to note here that through a comparative, penetrating study of the dissimilatory pathways of microbial metabolism distributed among numerous types of bacteria, the great Dutch microbiologist A. J. Kluyver discerned that the recurring patterns in the variety of metabolic pathways are but few elementary reactions such as transhydrogenation, transphosphorylation, decarboxylation, etc[4]. From this was developed the concept of unity of biochemistry. A certain chemical conversion occupies a predominant position in a particular microorganism. For example, the conversion of pyruvate into acetaldehyde by pyruvate decarboxylase is predominant in yeasts which carry out alcoholic fermentation but is absent in lactic acid bacteria which carry out lactic acid fermentation.

Regulation. The existence of regulatory mechanism can be traced to the discovery in 1861 by Louis Pasteur, who observed that despite the lower consumption of glucose, more yeast is formed in the presence of air than in its absence (Pasteur effect)[5]. It stimulated intensive research on identification of the control sites in catabolism of glucose. Later, the observations that addition of certain amino acids to bacterial cultures shuts off the entire sequence of reactions, leading to the formation of the amino acid, led to the formalization of the concept of feedback inhibition[3]. The phenomena of induced synthesis of enzymes and the existence of specific membrane transport protein (permease) were discovered from studies dealing with growth and nutrition of bacteria[3].

Photosynthesis. The green cover on the earth has inspired many authors to comment that it is because of the remarkable process of photosynthesis invented by the plant chloroplast that man obtains food for himself and his cattle, fibre for his clothing, wood for fuel, his boat and his flute, and the paper for writing his poetry or scribbling his philosophy. A cover-up here? 'Chloroplasts did not evolve as a part of the plant cell; they were acquired by the (evolving) plant cell from the bacterial world through endosymbiosis', says Woese. 'In other words', he says, 'it is the bacteria that have invented photosynthesis, and plant chloroplasts are merely domesticated cyanobacteria'. The cyanobacteria are the most self-sufficient organisms in the biosphere. They not only carry out photosynthesis but also fix gaseous nitrogen from the atmosphere into biologically useful nitrogen compounds – a biochemistry which a vast majority of organisms are incapable of.

'We owe a debt of gratitude to the microorganisms whose peculiarities have provided a general insight into the understanding of photosynthesis', said van Niel[4]. What an ingenious use Engelmann (1880) made of certain motile bacteria as sensitive indicators of oxygen to demonstrate the direct connection between oxygen evolution and light absorption by chloroplasts in *Spirogyra* filaments! By illuminating the alga with light from a prism, he was able to determine the action spectrum of photosynthesis[4].

It was on the basis of the knowledge of a variety of microorganisms and the application of the concept of the unity of biochemistry developed by his master, A. J. Kluyver, and most importantly on the basis of the observations that (a) several types of bacteria can synthesize their cell material from CO_2 without the benefit of radiant energy, (b) the purple sulphur bacteria can grow anaerobically in a minimal medium supplemented with sulphide and bicarbonate, provided they are exposed to light, and (c) photosynthetic activity of the purple bacteria is not accompanied by evolution of O_2, that van Niel was led to conceptualize photosynthesis as a photochemical oxidation–reduction process and formulate his famous equation[4]:

$$\underset{\text{H donor}}{2H_2A} + \underset{\text{H acceptor}}{CO_2} \rightarrow \underset{\text{Oxidized H donor}}{2A} + \underset{\text{Reduced acceptor}}{(CH_2O)} + H_2O.$$

What this equation implied was that plant photosynthesis and bacterial photosynthesis are fundamentally similar light-dependent reactions. The difference is in the hydrogen donors they employ – being H_2S in the case of sulphur bacteria and H_2O in the case of the green plants. A direct consequence of the above-mentioned general formulation was the prediction that O_2 produced during photosynthesis by the green plants must come directly from water and not from CO_2.

Chemosynthesis. It was through the study of the life-style of a number of bacteria (nitrifying bacteria, sulphur bacteria, iron bacteria, etc.) found in nature under aerobic and anaerobic conditions that it was discerned that in addition to photosynthesis there is another process, chemosynthesis. In chemosynthesis the organic matter of the organism is built from CO_2 as the sole source of carbon without the supply of the radiant energy. As was first shown by the Russian microbiologist Winogradsky, a variety of bacteria can derive energy for growth from the oxidation of inorganic compounds[3,6]. That chemical energy can be derived from the biological oxidation of hydrogen, sulphide, sulphur, ammonia, carbon monoxide, ferrous, etc., was a revolutionary idea. It showed the apparently diverse ways in which microorganisms have solved the problem of

providing for their indispensable energy requirements.

Chemosynthesis had been thought to be a rare phenomenon until 1977, when scientists took a submersible at a depth of some 3000 m in the Pacific ocean. They discovered jets of superheated black water ejecting from the ocean floor and mixing with the cold sea water[7,8]. They were astonished to see a luxuriant fauna thriving in the warm water, in the vicinity of the hydrothermal vents (Figure 2). What is the food source for these new forms of animal life in the permanently dark environment? Pioneering work by Holger Jannasch showed that the ecosystems of animal populations are supported by microbial chemosynthesis rather than photosynthesis[7]. A variety of chemoautotrophic bacteria live in dense populations in the animals. The bacteria obtain energy by oxidizing geothermally provided reduced sulphur compounds and fix inorganic carbon through the Calvin–Benson pathway (Figure 3). The organic carbon is taken up by the animal hosts. The hosts are among the few animals on earth that are not fed directly by photosynthetically fixed carbon.

Thermophilic microorganisms. In the last decade another revelation occurred in microbiology. Karl Stetter isolated anaerobic archaea from sulphur-rich, marine volcanic environments that are able to grow at extremes of temperatures[9]. The upper temperature limit of life was pushed up to 110°C. Microbiologists are competing to see who can find microorganisms that beat this record!

The diversity of hyperthermophilic archaea has, in turn, started the race to discover the enzyme which has the highest degree of thermostability. Incredible it may seem, but an α-amylase from *Pyrococcus furiosus* retains enzyme activity even after autoclaving at 120°C for 5 h (ref. 10)! These microorganisms are the focus of the emerging area of biocatalysis at extreme temperatures and for biotechnological opportunities.

Early life. And yet another revelation. Thomas Gold predicted that microbial life is widespread at depth in the crust of the Earth[11]. He believes that in mass and volume the subcrustal life may be comparable with all surface life. Some microbiologists have sampled fluids from borewells drilled some 4000 m into the granitic rock or into the sea bed and have reported finding thermophilic anaerobic bacteria[12,13]! These surprising findings have fundamentally altered the views on the physical setting under which life arose and of the nature of early life on earth. Life probably arose in a hot environment. The ancestor may have been a chemosynthetic thermophile[14].

Figure 2. Giant tubeworms, *Riftia pachyptila*, at hydrothermal vent (courtesy of IFREMER, France).

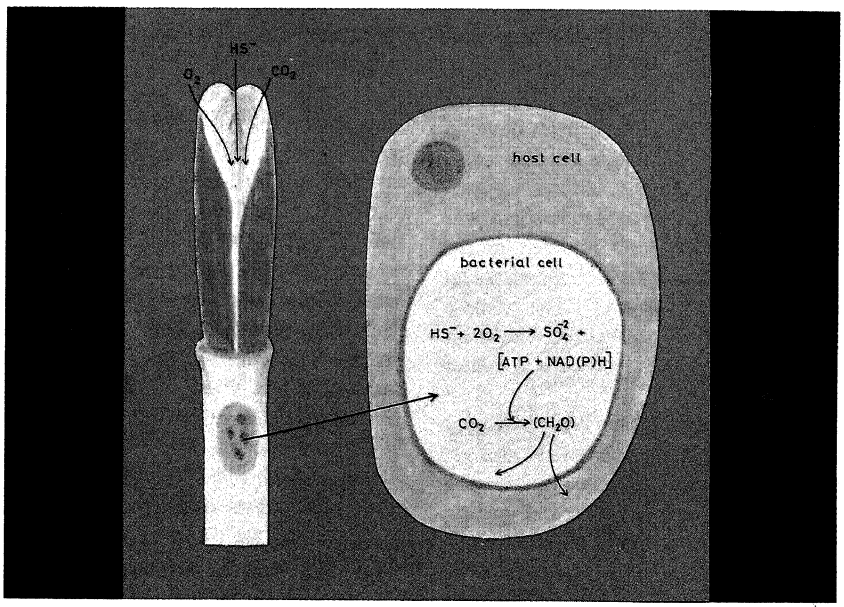

Figure 3. Schematic representation of symbiotic relationship between *Riftia* and chemosynthetic bacteria. Hydrogen sulphide serves as the electron donor, or energy source. The energy is produced when hydrogen sulphide and oxygen are combined and it is used for fixation of CO_2 (based on refs 7, 8).

Microbial diversity. 'The essence of the microbial world lies in its diversity', says Woese[2]. An innovative application of the techniques of molecular biology has been made to estimate how much of microbial diversity had escaped detection by conventional pure-culture technique in an

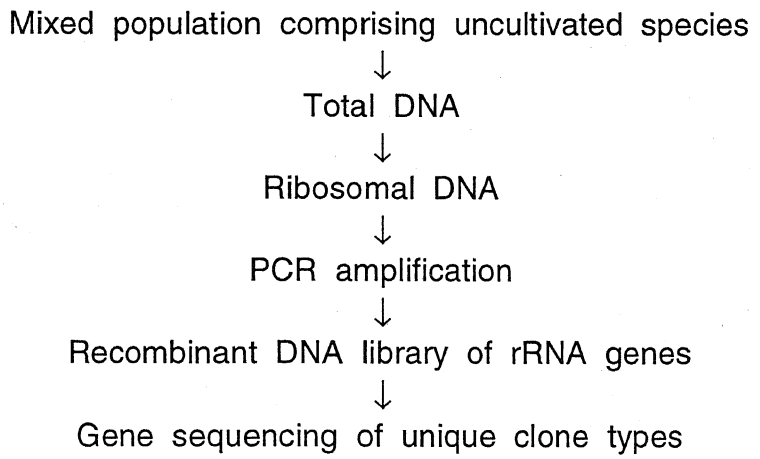

Figure 4. Sampling of microbial populations through isolation and sequencing of ribosomal RNA genes directly from the environment[15].

already well-studied place. Norman Pace took a census based on unique ribosomal RNA genes extracted and cloned directly from a niche (Figure 4)[15]. He demonstrated that more species of archaea were present than suspected.

It has been estimated that of the total number of species of bacteria (40,000) and the fungi (150,000), only about one-tenth have been discovered[16]. The fascination for microbial diversity comes from their strangeness and their exotic habitats. J. R. Postgate[17] gives a fascinating account of the specialized microbes which live at the bottom of deep oceans, in the mud in the estuaries of the rivers, in sewage treatment plants, in the interior of compost heaps, in the rumen of cattle, in near-boiling sulphuric acid conditions, in alkaline environments equivalent to a solution of caustic soda, in strongly salty places, in root nodules of leguminous plants, etc. A generalization that can be made from the results of microbiological sampling of diverse habitats is that no matter how harsh the conditions are in nature, so long as liquid water is available, microbial life will be found.

The importance of studying diversity has been beautifully stated by David Perkins[18]:

'Knowledge of a flute or a kettledrum is not sufficient to understand all the other instruments in a symphony orchestra or to predict their characteristics. Nor is a knowledge of a single species, however complete, adequate for understanding diverse species. Diversity of research organisms in the laboratory must at least dimly reflect the diversity of species in nature if the scope and beauty of evolutionary improvizations are to be appreciated and the genetic manipulation that brought them about are to be understood.'

Some other contributions of microbes. Before this 'refresher' course is closed, let us cast a final breezy look. Other examples where microorganisms contributed to new discoveries are: gene regulatory proteins[19], simplest light-driven proton pumps in halophilic bacteria[19], restriction modification system[19], random and directed mutations[20], checkpoints in cell cycle[21]. Lest we forget, the success in obtaining nutritional mutants in the fungus *Neurospora crassa* had led to the discovery of the relationship between genes and enzymes. The formulation of one-gene–one-enzyme hypothesis by Beadle and Tatum had sparked a revolution in biology.

The study of microorganisms has been central to the effort to understand life. We are still searching for answers to numerous fundamental problems. Where will the answers come from? As in the past, in large part from the study of microorganisms.

Investigation and inquiry

How is it then that in spite of an impeccable record of microbiology, its flag is at half-mast? Surprising as it seems, but professors and students genuinely interested in microbiology are indeed very few, as observed by Woese[2]. Is it that the contributions of microbes to biology is consciously or unconsciously covered up in the teaching of biology? Or, is it that the repeated assertion that 'what is true for *E. coli* is also true for elephants' generated the impression of the futility of gaining fundamentally new information, particularly when encyclopaedic information is already available on *E. coli*[18]?

The major fault in the teaching of microbiology (and other sciences) is that emphasis is placed on facts, instead of on observations and experiments. Invariably, the eminent microbiologists record that their curiosity and interest in microbiology were aroused from the excitement in collecting samples of some pond water or marine sediments or soil from some tropical forests or from some frigid place, from the suspense in waiting for microorganism to appear in an enrichment medium, from the fascination of the diversity of their types, from the microscopic observations of motile bacteria or of the intricate configuration of fungal spore walls, from the challenge of designing conditions for mass culturing a tractable organism, or from puzzling over the special features of the biochemistry which allows a particular microorganism to live in its ecological niche and cope with the environmental stress[22–25]. The eminence of these microbiologists comes from their realization that each microbial species is a unique, intrinsically valuable and a source of new knowledge.

Microbiological research

Extremophiles. Given the widely different level of scientific and technological development, the limited funds for science in our country, can we contribute to the vitalization of microbiology? The answer is a clear yes. I propose that research on extremophiles – the microorganisms which are indigenous to unusual habitats – may be a starting point. Perhaps, a fascination for the extremophiles as source of good biological questions and as new materials for new products and processes may usher a renaissance in microbiology in the country. India, with its diversity of natural habitats (desert, alpine and tropical soils, hot springs, porous rocks, glaciers, lakes, sediments of streams, caves, alkaline soils, brackish marshes, coastal lagoons, ocean, etc.) and a variety of man-created unusual habitats (composts, municipal waste dumps, sewage digestors, stagnant waters,

oil-contaminated areas, areas receiving industrial waste discharge, effluents of acid mines, corroded materials, etc.), presents great opportunities for the investigations of extremophiles. Because unusual habitats occur across the length and breadth of the country, research on extremophiles may well be one of the best ways to reach out and encourage scientists in the remote and less endowed institutions. Moreover, extremophile research is an area in which, because of the paucity of information, these scientists can contribute to the generation of knowledge, accomplish something and not feel frustrated. The pioneering studies of Thomas Brock on thermophilic microorganisms were done in remote places with simple facilities[26]. Could any one have predicted that the bacterium *Thermus aquaticus*, isolated in 1969 by Brock and Freeze from a hot spring in the Yellowstone National Park, USA, would in less than 20 years be exploited as a source of thermostable DNA-copying enzyme (*Taq* polymerase) and make the PCR technology an enormously successful technique? This enzyme and many restriction enzymes discovered from screening of thousands of bacteria and archaea are now churning millions of dollars annually in the developed countries. Witness the *Taq* polymerase controversy[27]. There was a time when people fought for the possession of women or for a piece of land. Now people are fighting for the rights to a bacterial gene product!

An understanding of life cannot be complete without a knowledge of the variations of biochemical design that evolved over many millions of years. Microbes offer unique experimental material for understanding the diversity of adjustments that they make to get adapted to their environment. Let us hope that the traditional areas of microbiology concerned with the study of the diversity of microbes and of their biochemical activities will be pursued vigorously.

Finding *patterns* in nature's maze: An endless quest

K. Chandrashekara

I am writing in response to 'Are patterns a rule in nature?'[1] by K. N. Ganeshaiah (KNG). Without doubt, reading it was quite a stimulating experience. However, I feel compelled to respond to a few issues raised in the paper; as the saying goes, it is better to debate an issue and not settle it rather than settle an issue without debating it.

Patterns: a question of scale

Are patterns a rule in nature? I find the question rather incomplete and bordering on the philosophical. What sort of pattern does the author have in mind? At what level of organization? At what temporal and spatial scales? To a physicist, chemist or for that matter any scientist, the answer to the question will be an assertive 'yes', given the fact that all matter in nature,

animate or inanimate, diamonds or DNA, represents a highly ordered arrangement of atoms. A historian sees a pattern in the evolution of civilization, an economist in share market fluctuations and a Coorg planter in coffee prices in the London market! They may, however, fail to see any pattern in short-range local events such as changing consumer tastes over a period of a few weeks or the variation in the onset of summer showers in April. Clearly, it is important to specify exactly what sort of pattern and scale one is dealing with before asking if patterns are ubiquitous.

What is a pattern: toward a definition

What is a pattern? As pointed out in the article, it is difficult to define what a pattern is. It is further argued that there may be disagreement among scientists on the signal component or specific feature of the system that is considered to reflect the pattern[1]. For this reason, the author says, it is difficult to define a pattern and that this constitutes a major difficulty in pattern finding in science. Perhaps not. Pattern is 'an arrangement or order discernible in objects, actions, ideas or situations' (*New Shorter Oxford English Dictionary*). Many of my colleagues when asked what the term pattern meant to them opined that the term pattern could be used to describe any phenomenon which is predictable. Unlike argued by KNG, it hardly matters what parameters are chosen to identify a pattern, because scientists from varied fields do recognize patterns in each other's fields though they may not fully understand the approach adopted in identifying the pattern.

In my opinion, what we probably have to split hairs about are the scientific merits and the criteria in classifying patterns as 'yes' or 'no' patterns. Taking the help of information theory, we can perhaps classify patterns. Many systems, be they organization of ideas or objects, carry information which has predictive value. Systems with '0' information content can be labelled 'no' patterns and those with information content of '1' as 'yes' patterns. Clearly, the information content will also influence the degree of predictability. Therefore, as pointed out by KNG, the patterns need not be discrete and there could be a continuum, at least in principle.

Patterns: good vs poor?

It is pointed out by KNG that there is a general agreement among scientists that patterns are an all or none phenomenon, notwithstanding his earlier argument that it is difficult to define what a pattern is and that it poses a major problem in pattern finding in science. He then expresses surprise that science immediately recognizes and appreciates '... demonstration of *absolute* "yes" patterns, more easily than that of "poor" or "no" patterns (italics mine)'. That is setting up a straw-man and shooting him down! As pointed out earlier, the crux of the matter is predictability and it is this feature which enables scientists to label something as a pattern. The reason why scientists do not appreciate a 'poor' pattern is because it is not explicitly labelled so. If a phenomenon concerning subatomic particles or stars has an information content which is greater than '0' (however small) and, therefore, has a certain level of predictability, it is labelled as a pattern.

Scientists are always aware of the inadequacy of a 'model' that explains patterns and it is unfair to say that no distinction is made between good, poor and no patterns. It is also true that as our knowledge about a phenomenon increases, the information content of the phenomenon may be revealed in greater detail and the predictability may also improve. This would result in a phenomenon being explicitly labelled as poor with hindsight, but for a given amount of knowledge and at any given moment there is merely a pattern or no pattern. Conversely, with increasing knowledge a 'yes' pattern may turn out to be a 'no' pattern. As an extreme example we can remind ourselves of Ptolemy's geocentric view of the universe, which was replaced by the heliocentric view – the well-known Copernican revolution.

A search for the 'ultimate particle' led Dalton to formulate the notion of indestructible atom; this he is known to have derived from the laws of visible heavenly bodies. But Humphry Davy was not convinced; he argued that 'there is no reason to suppose that any real indestructible principle has yet been discovered'. It took 50 years for science to prove Humphry right. However, by then, the concept of indestructible atom was used and elaborated by Gay-Lussac, Avogadro and Mendeleyev. The blow to indestructibility of atom came from two sources, the study of light and the discovery of electricity, the latter being totally unexpected[2]. The early history of physics and chemistry is peppered with many similar events that tell us three things; (i) that patterns when discovered are questioned; (ii) that even if the pattern is 'poor', considerable progress can be made in understanding nature and (iii) that the poor pattern may turn out to be a good pattern as we acquire more knowledge.

It is, therefore, not quite correct to say that science does not distinguish between good and bad patterns. When subjects in a psychological test are given a choice between various visual patterns and asked to sift the good from the bad, it is understandable, because they have a choice of 'alternatives'. Now how am I to say that the return of the Haley's comet once every 75 years, or the life-cycle of 13-year cicada is a good pattern or a bad pattern? If a good pattern is 'invariant' or has fewer or no 'alternative states', it again boils down to predictability or regularity, fewer the alternatives or alternative states, greater is the predictability. Which means we can now define a pattern in terms of predictability. If the predictability is greater than 0, we can claim to have discerned a pattern, however poor it may be. Once that is done, the scientists would like to take the predictability as close as possible to 1. This represents the range of patterns exemplified by Ganeshaiah's ink blot to a square or a circle. I argue that science has not instinctively picked the good patterns but has only so far described what is obvious; squares and circles – one of the two ends of the continuum. It would take more effort and time for science to traverse the entire range from both ends. Towards this the scientists are justified in using all the tools that are at their disposal and such attempts need not be dubbed 'frustrating search for patterns'.

Patterns and perception

KNG's major criticism is that our ability to detect patterns is limited by our perceptual abilities. This may indeed be so as philosophers right from Plato have emphasized. Given this handicap, how are we ever going to decide what is a 'good' pattern? A martian with better perceptual ability may throw out all our

'good' patterns as 'no' patterns! Our visual sense of a stick held in water deceives us to believe that the stick is bent at the water surface. How can we demonstrate that the stick is straight? Simple, by running our hand down the stick. Herein lies our folly and by extension the general tentativeness of all our discoveries. Because in our eagerness to prove an error in our sense of vision, we have trusted our sense of touch. In other words, how can 'deceptive tools' prove their own deception? However much we dislike it, we have to contend with our limited array of senses, suspect or not, to go about the job of discovering patterns in nature. Though we cannot assert that patterns abound everywhere in nature, we have to tap them using our limited tools. It is likely that as we polish nuggets of information and discover more and more of the hidden treasures, we will carve even more patterns from nature. If all this is the construct of the language and grammar of science, so be it. Roger Boscovich, a mathematician and physicist of the eighteenth century has gone beyond this and argued[3] that exploiting determinism to obtain complete knowledge is not possible because '... our human intellect is not equal to this task ...'.

It has been rightly argued that randomness is in the eye of the beholder and is a function of the power of our models to analyse the phenomena. Most of us have the experience of fitting our observed data points into one or more models. In the process, if we have been successful, it only shows that we have been able to explain the observed phenomena in some predictable way. I see no harm in such an exercise. Data fitting to wrench a pattern is a routine exercise through accepted rules of the game of science. Transformation of data is a legitimate practice. If log-transformation enables me to gather a greater comprehension of my observations (more patterned or less patterned), what is the harm? But for noise filters in radio and television, we would not be enjoying music, a pattern of sound.

Sure, as KNG points out, some amount of data or chips of information may be lost as noise in the process, but is it important? For instance, if a certain method of short-range forecasting of the possibility of rain in a particular week of the year is going to be predicted at some assured level of probability, even if it is not very close to 1, I am willing to lose any amount of information as noise through all the 'frustrating' jugglery!.

It required the mental acumen of great men to unravel patterns in nature about us where none was realized earlier. As Alexander Pope wrote, 'Nature and nature's law hid by night; God said, let Newton be and all was light'. To see woods from forest requires some skill and time. And seen it would be, definitely. So, if a hundred Newtons with their powers of senses identify patterns all around us, why complain. Certainly, it is our naivety to chide them that they are squeezing nature dry of 'no' patterns. Even in arts we need artists who see appealing patterns around them. I would welcome a hundred Michelangelos or Jakanacharis, who imposed *their* patterns onto stone – without their patterns the world would have been such a dull place.

Patterns: stochastic or deterministic?

I do not think that it is a general attitude of science to attribute an order-generating process to any pattern[1]. Science does not underplay or has disregard for the role of randomness in generating order. Stochastic processes are invoked as often, if not more, as are deterministic processes in describing patterns. Indeed, before the notion of chaos became an established concept, scientists addressed a complicated process as a statistical problem – a random process[3]. It is true that it took a long time for science to shed the blinkers of deterministic clockwork of the Newtonian world view – 'laws that never shall be broken'[3]. We now know that in a large number of physical systems, from heart beat to weather, the slightest uncertainty in the knowledge of the system at one moment will result in complete loss of information about the state of the system in a very short time and where randomness appears to prevail.

It is true that only recently have we begun to realize the power of randomness more explicitly in generating order, especially in biological sciences. Even here, for example, the so-called order we see in the evolution of organic diversity is a result of random or chance process. Evolutionary biologists agree that if the tape of evolution were to be rewound and run again, we cannot be certain that we will see an amoeba-like organism again; leave alone *Homo sapiens* or a *Tyrannosaurus rex*! Natural selection is not an order-generating process, it merely represents the success or failure of individuals of a species to respond to randomly changing local conditions.

The ability to find patterns has had a long evolutionary history. It was perhaps the ability of our australopithecine ancestors to find patterns in the movement of animals which helped them hunt, escape predators, and avoid other groups of competing individuals; later on, the same ability must have even enabled them to light fires. The success of australopithecines was due perhaps more to this than their erect posture or the ability to make tools! Human beings are known to make sense of their surroundings by making a 'mental representation' of what they see – an important feature of cognition. Given this it is not surprising that we try to find pattern in everything that impinges on our senses. I would even argue that this constant search for patterns contributed in no small measure toward the enlargement of the forebrain to which *Homo sapiens*, as a species, owes its success today.

I have deliberately not attempted to respond to the philosophical aspects of the question raised by KNG: simply because when I see a brick or a chair, I see *it*. I find it difficult to subscribe to the kind of philosophy which argues that a brick or a chair does not exist – it is only an interpretation of the human mind. It has to be. Even in Ganeshaiah's imaginary planet 'Binearth' we *need* a biologist from earth to study and interpret life on the planet. It is difficult to comprehend how the universe can be visualized without the existence of cognitive beings (for whom and by whom anyway?). The world is, what the mind sees. There is, in my opinion, no question of imposing anything.

Lastly, I do not think that science looks for patterns for its own survival. A very interesting pattern relating to the sounds produced by humans has been discovered recently. It concerns the case of two individuals with mild brain damage who were otherwise normal. It seems these two individuals were unable to pronounce vowels while being perfectly capable of pronouncing consonants. This provides yet another example of the 'pattern' of modular construction of human mind and

also suggests that categorization of sounds into vowels and consonants is a pattern. It may be *imposed* by human mind, so what? It could not be otherwise! Now if such pattern finding is going to ensure the 'survival' of neurologists and the growth of neuroscience, the 'last frontier in biology' we should only be too happy.

With surprises such as the one mentioned above being sprung on us from time to time, it may not yet be time to suspect that patterns are not a rule in nature. As Einstein said, 'the eternal mystery of the world is its comprehensibility', and toward this we should continue our search for patterns.

I am not sure if I have 'not settled' the issue by 'debate', but as Popper said, 'I may be wrong and you may be right and, by an effort, we may get nearer to the truth'.

MEETINGS/SYMPOSIA/SEMINARS

National Workshop on Biodiversity Conservation in Managed Forests and Protected Areas

Date: 29 November –1 December 1995
Place: Bhopal

Topics include: Biodiversity conservation in managed forests; Biodiversity in protected areas; Ethical and ecological considerations; Socio-economic issues; Institutional, policy and planning issues.

Contact: Prof. P. C. Kotwal
Indian Institute of Forest Management
P.O. Box No. 357, Nehru Nagar
Bhopal 462 003
Phone: 575716, 64268, 67851
Fax: 91-755-572878

Xth National Carbohydrate Conference

Date: 8–9 November 1995
Place: Vallabh Vidyanagar

Topics include: Plant and microbial polysaccharides; Isolation, characterization and their biological activity; Carbohydrate synthesis; Industrial polysaccharides; Production and utilization; Carbohydrate fermentation/Biotransformation.

Contact: Prof. M. N. Patel
Convener
Department of Chemistry
Sardar Patel University
Vallabh Vidyanagar, Kaira 388 120

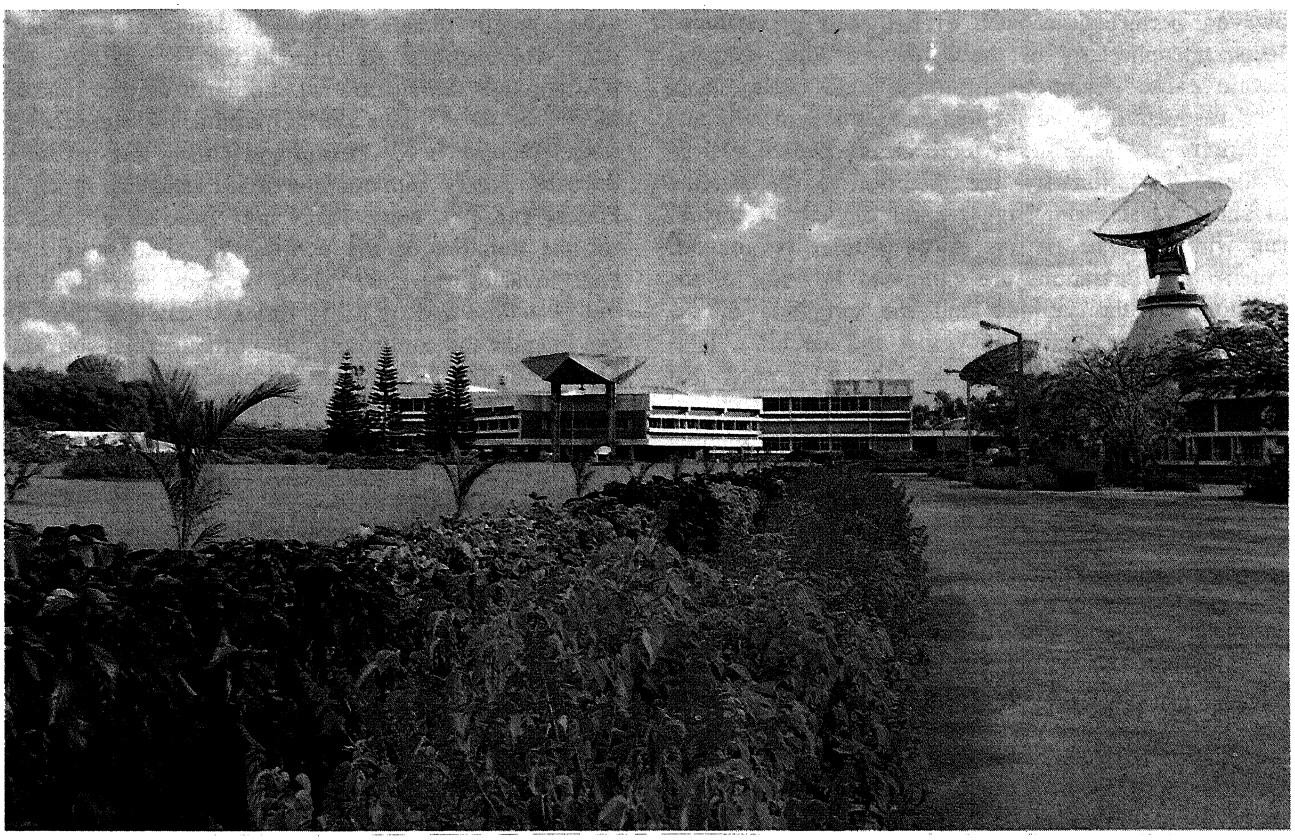
INSAT Master Control Facility: An insight

S. Rangarajan

An overview of the activities at the INSAT Master Control Facility (MCF) located at Hassan is presented. After a brief account of the INSAT services, the major subsystems of the spacecraft and their interrelationships are brought out. Important operations in different phases of the mission are described. The maintenance of these satellites in the geostationary orbit calls for periodic station keeping manœuvres. Facilities exist at MCF for carrying out these operations and also to provide support for the satellite users. A bird's eye view of the facilities is also included in the article.

The Master Control Facility (MCF) is the only mission control centre for the INSAT satellites – past, present and future. It is located about 8 km north of Hassan town on way to the historic monuments of Halebeedu. What immediately catches the eye for a newcomer is the number of antennae looking like giant-sized cups propping up over a green line of trees. Unlike the sunflowers in the fields around, these antennae at MCF seem to be pointed for ever into the vast emptiness of space. Actually they are looking towards and communicating with those satellites which have come to revolutionize our life-styles in the last decade. INSAT satellites are placed in the geostationary orbit, a circular one in the equatorial plane, at an altitude of around 36,000 km, a height at which the period of revolution synchronizes with that of earth's rotation. From there about 42% of earth's surface is accessible for line-of-sight communication using an antenna pointed in a fixed direction.

The services provided by INSAT satellites have grown steadily both in terms of quantity and in terms of new services. In addition to traditional applications in the areas of telecommunication, TV and radio broadcasting and imaging for meteorological purposes, INSAT has several unconventional services like the collection of local meteorological data from remote unattended platforms, relay of zone-specific disaster warning messages, standard time and frequency distribution, tele-education, search and rescue system, etc. In fact, some of the services are not widely known, for example, the high-quality sky radio channels which are being distributed as an add-on to the regional language TV transmissions.



Spacecraft subsystems
